From 1871 to 1873 Stephens edited the *Atlanta Southern Sun*. His published works include *A Constitutional View of the Late War Between the States* (1868-70), perhaps the best statement of the Southern position with reference to state sovereignty and secession; *The Reviewers Reviewed* (1872), a supplement to the preceding work; and *A Compendium of the History of the United States* (1875; new ed., 1883).

See Rudolph Von Abele, *Alexander H. Stephens* (1946).

**STEPHENS, JAMES** (1882-1950), Irish poet and storyteller whose pantheistic philosophy is revealed both in his fairy tales set in the Dublin slums and in his compassionate poems about animals, was born in Dublin on Feb. 2, 1882. He was a solicitor's clerk when *The Crock of Gold* (1912), with its fabulous Celtic theme, established his fame. But he also knew urban poverty (his theme in *The Charwoman's Daughter*, 1912), and his astringent irony suggests affinities with James Joyce. He wrote *The Demi-Gods* (1914) in a similar vein, and (having learned Gaelic) *Deirdre* (1923) in more formal, rhythmic prose. Short stories and lyric poems constitute the remainder of his work. Stephens was actively connected with the Irish nationalist movement. By 1940 he was living in London, and having discovered himself as a broadcaster of genius, was frequently on the air from 1939 until his death in London on Dec. 26, 1950. (P. Ar.)

**STEPHENSON**, the family name of three English engineers prominent in the development of railways.

**GEORGE STEPHENSON** (1781-1848), inventor and founder of railways, was born at Wylam, Northumberland, on June 9, 1781. His early life was spent in extreme poverty, but in 1804 he moved to Killingworth, Northumberland, supplementing his meagre income by repairing watches and clocks, and in 1812, after seriously considering emigrating, was appointed engine-wright of High Pit colliery at a salary of £100 per year. It was there that, in 1815, he designed and produced his version of the miners' safety lamp, while Sir Humphry Davy was still carrying out experiments. When Davy's lamp did appear there was violent controversy as to who should receive the credit for the invention.

About this time also Stephenson was given financial backing to produce for the colliery a "travelling engine" from pit-head to the port. It was a success and when, in 1822, the Stockton and Darlington railway was under construction, he persuaded the directors to use steam instead of animal traction. The railway opened on Sept. 27, 1825, and the first public passenger train in the world was drawn by Stephenson's "Active," later renamed "Locomotion." When the Liverpool and Manchester railway was nearing completion, Stephenson again persuaded the directors to try locomotives; a prize of £500 was offered for a suitable locomotive and was won by his "Rocket." Eight engines in all were employed when this line opened on Sept. 15, 1830, all having been built at Newcastle, in the works he founded with his cousin, Thomas Richardson, and a colleague, Edward Pease. Stephenson was engineer of many other railways in the midlands, but strongly disapproved of the "railway mania" which reached its climax in 1844. He was also consultant to many foreign companies, notably in

Belgium and Spain. His last years were spent in retirement at Tapton house, Chesterfield, where he died on Aug. 12, 1848. (See also RAILWAY: *Locomotives*; STEAM.)

**ROBERT STEPHENSON** (1803-1859), who specialized in the construction of railway bridges, was born at Willington Quay, Northumberland, Oct. 16, 1803, the only son of George Stephenson. Educated at Bruce's academy, Newcastle upon Tyne, and Edinburgh university, in 1819 he was apprenticed to Nicholas Wood at Killingworth. In 1821 he assisted his father in a survey for the Stockton and Darlington and Liverpool and Manchester railways, but failing health in 1824 led to his accepting a mining appointment in South America. Recalled to England in 1827 to take up work on locomotives at Newcastle, he was able to overcome the problem of securing boiler tubes, a problem that had been giving much trouble to the designers, and he was responsible for most of the improvements to locomotives at this time. In 1833 he was appointed engineer of the London and Birmingham railway; while holding this appointment he carried out a number of engineering feats, such as the Blisworth cutting and the Kilsby tunnel. This railway proved to be a great success and was the first to run into London from the industrial north.

Robert Stephenson, however, was particularly concerned with the construction of tubular girder railway bridges and his work extended to Sweden, Denmark, Belgium, Switzerland and Egypt. The more notable examples were the Britannia tubular bridge over the Menai straits, the tubular bridge over the river Conway and the Victoria tubular bridge over the St. Lawrence river at Montreal. In 1847 he entered parliament as conservative member for Whitby, retaining the seat until his death in London on Oct. 12, 1859. (See also RAILWAY.) (T. M. S.)

**GEORGE ROBERT STEPHENSON** (1819-1905), the nephew of George Stephenson (1781-1848), was born at Newcastle upon Tyne on Oct. 20, 1819. After working in colliery workshops near Manchester, he was sent to King William's school, Isle of Man. After his father's death in 1837 he worked for his uncle in the drawing office of the Manchester and Leeds railway. In 1860, when he was consulting engineer to the provincial government of Canterbury, New Zealand, the Lyttelton-Christchurch line was built under his direction. He returned to England and with Sir John Hawkshaw in 1864 built the East London railway. He was partly responsible for the construction of the Victoria tubular bridge across the St. Lawrence and designed many bridges in England and abroad. In 1859 he succeeded his cousin Robert Stephenson at the locomotive works at Newcastle upon Tyne, and at the Snibston and Tapton collieries. He died at Cheltenham on Oct. 26, 1905.

**STERCULIACEAE**, the cacao or chocolate family of plants, consisting of about 50 genera with 1,200 species of tropical or subtropical trees, shrubs and herbs. Five genera (*Ayenia*, *Fremontodendron*, *Hermannia*, *Melochia* and *Waltheria*) have representatives in southern United States. The leaves of Sterculiaceae are alternate and simple or palmately compound; flowers, often unisexual, are solitary or clustered and have three to five sepals and five or no petals. The usually numerous stamens are separate or joined into a column and the superior ovary has two to five cavities or separate parts. The fruit is fleshy, or dry and generally capsular. Important plants of the family include cacao (*Theobroma cacao*), source of cocoa (*q.v.*) and chocolate; cola (see KOLA NUT) (*Cola nitida* and *C. acuminata*), which yields a stimulant used in cola drinks; and a few *Sterculia* species (especially, *Sterculia urens*), which yield karaya gum, an important substitute for tragacanth (see GUMS, PLANT). Species of a few genera are cultivated as ornamentals, notably bottle tree (*Brachychiton*), dombeya (*Dom-*

E. AUBERT DE LA RUE

BOTTLE TREE (*BRACHYCHITON RUPESTRIS*), COMMON TO AUSTRALIA

beya), Chinese parasol tree (*Firmiana*), flannel bush (*Fremontodendron*) and sterculia (*Sterculia*).

In geologic times the family was distributed far beyond the limits of the present tropics and subtropics; e.g., into Alaska.

(J. W. Tr.)

**STEREOCHEMISTRY.** Following are the main sections and divisions of this article:

## I. INTRODUCTION

The term stereochemistry (from Gr. "solid," + chemistry) is applied in a wide sense to all that part of physical science which deals with those properties of chemical compounds which are believed to be due to the relative positions of the different atoms within a single molecule, or to the relative positions of different molecules in a larger aggregate of material. In this article, however, the term is used in a narrower sense.

The following discussion is almost entirely limited to such aspects of the subject as are included in the field of stereoisomerism (see ISOMERISM), and it deals only with the stereochemical properties of individual molecules or ions. (For other aspects of the subject, which are largely ignored here, see CRYSTALLOGRAPHY; Crystal-Structure Analysis; ELECTRON DIFFRACTION; SPECTROSCOPY.)

One important goal of the structural theory of organic chemistry (knowledge of which is here assumed, see CHEMISTRY: Organic Chemistry; ISOMERISM) is to associate with the molecule (or with each of the ions, see MOLECULE) of each distinct compound a diagram, known as its structural formula or structure. The purpose of such a diagram is not to represent the true Euclidean geometry of the molecules of the substance; it is rather to specify the valences of the various atoms (i.e., the numbers of lines which terminate at the corresponding atomic symbols) and the numbers of bonds between the various pairs of atoms (i.e., the numbers of lines drawn between the corresponding pairs of atomic symbols).

About the middle of the 19th century, it was discovered that in certain instances the methods of structural chemistry led to the assignment of the same structural formula to more than one compound. It was, therefore, evident that the rules of structural chemistry were, in these instances, insufficient for the complete

identification of the compounds in question. The theories of stereochemistry (in the narrower sense) were devised as the corrections necessary to remedy this defect. It proved possible to account for the number of distinct compounds to be associated with each structural diagram if two molecules of the same substance were assumed always to have not only the same structure, but also the same arrangement of their atoms in space. This geometrical interpretation has received independent support from the data derived from studies of X-ray and electron diffraction and of spectra. Consequently, although the possibility of an alternative, non-geometrical explanation of the observed numbers of isomers had not been seriously explored, the correctness of the geometrical interpretation was generally accepted without question in the 1960s. In the present article it is assumed explicitly.

For the sake of definiteness, but at the expense of anticipating and duplicating a small part of the discussion in subsequent sections, a specific example of the way in which stereoisomers are considered to differ geometrically may be given here. The two different 1,2-dichloroethylenes, which possess the same structure  $\text{CHCl}=\text{CHCl}$ , are thought to have the different geometrical forms represented by the following planar diagrams.

## II. EARLY HISTORY OF STEREOCHEMISTRY

**1. Optical Activity.**—The original approach to the subject of stereochemistry arose from a study of certain optical phenomena. In 1811 D. F. Arago discovered that crystals of quartz are optically active (i.e., that they rotate the plane of polarization of plane polarized light). That this optical activity (or rotatory power) is not restricted to crystalline solids was demonstrated by J. B. Biot, who found in 1815, and later, that oil of turpentine and aqueous solutions of tartaric acid or of sugar are optically active, and in 1817 that even gaseous turpentine is also active.

**2. Specific Rotation.**—For the characterization of an optically active substance, the so-called specific rotation (introduced by Biot in 1836) has proved useful. This quantity is defined by the equation

$$[\alpha]_{\lambda}^t = \frac{\alpha}{ld}$$

where  $[\alpha]_{\lambda}^t$  is the specific rotation for light of wavelength  $\lambda$  at the temperature  $t^\circ$ ; and  $\alpha$  is the rotation (in degrees) produced by passage of the light through a tube  $l$  decimetres in length, which is filled with the optically active substance (either pure or in solution) at a concentration of  $d$  grams per cubic centimetre. The rotation is taken with the positive sign if it is to the right (i.e., in the sense which is clockwise when regarded in the direction contrary to that in which the light is traveling), and with the negative sign if it is to the left (i.e., in the opposite, counterclockwise sense).

Ideally the specific rotation, as so defined, should be a characteristic property of the substance to which it applies, and its value should be independent of the experimental conditions. In practice, however, it varies somewhat in magnitude with the wavelength of the light, with the temperature, with the solvent (if any) and with the concentration. In a few instances, even the sign of rotation is found to change with conditions.

With colourless compounds, the variation in specific rotation with the wavelength of the light used is ordinarily small, but nevertheless great enough to make necessary the precise statement of the wavelength. The remaining variations are usually counteracted by standardization of the experimental procedure to as great an extent as possible. Thus, unless statements are made to the contrary, specific rotations are considered to apply to room temperature and to dilute solutions in specified solvents. Within these limitations, specific rotations may be employed for the

characterization, identification and even quantitative analysis of optically active substances.

**3. The Work of Pasteur.**—After the discoveries of polarized light and of optical activity, the next important advance toward the modern stereochemical theories was made by Louis Pasteur in a series of investigations on tartaric and racemic acids, carried out chiefly during the years 1849–53. These two acids not only have identical chemical compositions but also possess the same structure  $\text{HO}_2\text{C}-\text{CHOH}-\text{CHOH}-\text{CO}_2\text{H}$ . Yet they show certain marked differences in properties. For example, racemic acid is much less soluble in water than tartaric acid and crystallizes with water of crystallization, whereas tartaric acid separates in anhydrous crystals; the most remarkable difference between the two substances, however, is in their effect on plane polarized light. Tartaric acid and its salts (the tartrates) are optically active; more specifically, they are dextrorotatory (*i.e.*, their aqueous solutions rotate the plane of polarization to the right). On the other hand, racemic acid and its salts (the racemates) are optically inactive.

Pasteur's discoveries arose out of a crystallographic investigation of tartaric acid. He observed that there was a certain lack of symmetry in the crystalline form of this substance of such a kind that the crystal was nonsuperposable on its mirror image.

FROM STEWART, "STEREO-CHEMISTRY"; REPRODUCED BY PERMISSION FROM LONGMANS GREEN & CO.  
FIG. 1.—(A AND B) ENANTIOMORPHOUS CRYSTALS OF SODIUM AMMONIUM TARTRATE

The crystal and its image thus differ in the same kind of way as the right and left hands. He prepared and examined 19 different salts of tartaric acid and found that each of these showed a similar lack of symmetry in its crystalline form. Thus fig. 1(A) represents the crystalline form of one of these salts, sodium ammonium tartrate. If the crystal possessed the full symmetry of the system to which it belongs, two faces, corresponding with the two shaded areas, should be found in the positions indicated by broken lines. These faces, instead of occurring eight times in the crystal, occur only four times (there are of course two corresponding faces on the back of the crystal not shown in the figure); such faces, occurring only half as frequently as the full symmetry of the crystal demands, are termed hemihedral faces. The sodium ammonium tartrate crystal, because of the presence of these hemihedral faces, is evidently nonsuperposable on its mirror image represented in fig. 1(B). In contrast to tartaric acid and the tartrates, racemic acid and such of its salts as Pasteur examined (with the exception of sodium ammonium racemate, *see below*) crystallize in symmetrical forms superposable on their mirror images. The optically active tartrates thus crystallize in dissymmetric forms, whereas the optically inactive racemates yield symmetrical crystals. (According to accepted terminology, an object is said to be dissymmetric if it is not superposable on its mirror image, and to be asymmetric if it possesses no element of symmetry whatever, *see below*. In discussions of stereochemistry, the word asymmetric is often used loosely in places where dissymmetric is intended; in the present article, however, the distinction is observed.)

Pasteur's chief discovery was made through investigating the exceptional racemate, sodium ammonium racemate, referred to above. Crystallized from water at a temperature below  $28^\circ\text{C}$ ., this salt yields crystals which, unlike those of the other race-

mates, exhibit hemihedral faces; the crystals, however, are of two kinds. Some are identical in form with those of dextrorotatory sodium ammonium tartrate (fig. 1(A)) and are in fact crystals of that salt. The other crystals differ from these only in that their hemihedrism is in the opposite sense; they are thus the realization of the mirror image of sodium ammonium tartrate and have the form represented in fig. 1(B). When picked out from the mixture and dissolved in water, they give a levorotatory solution (*i.e.*, a solution which rotates the plane of polarization to the left). The acid obtained from these crystals has a crystalline form which is the mirror image of that of tartaric acid, and its solutions are levorotatory. It is to be regarded as a second variety of tartaric acid.

This new form of tartaric acid and the original one have exactly the same melting point and specific gravity; moreover, they exhibit exactly the same chemical reactivities toward all optically inactive reagents. Two substances related in this manner are said to be enantiomorphs of each other. (The further expressions antimers and optical antipodes are also frequently used.) A more detailed discussion of the ways in which such pairs of substances resemble each other, and of those in which they differ from each other, is given below (*see Enantiomorphs*, below).

On the basis of his discoveries, Pasteur postulated that, in consequence of the arrangement of their constituent atoms in space, the individual molecules of any optically active substance must be nonsuperposable on their own mirror images (*i.e.*, that they must be dissymmetric). Moreover, he postulated further that the molecules of any optically active substance must be superposable on the mirror images of the molecules of the enantiomorph of that substance. The situation visualized by Pasteur can be made more concrete with the aid of a rough analogy. The molecules of, say, dextrorotatory tartaric acid may be compared with right-hand gloves, whereas those of its levorotatory enantiomorph may be compared with left-hand gloves. No glove is identical with its own mirror image, but any right-hand glove is identical with the mirror image of any left-hand glove, and vice versa. If the analogy is carried a step further, a crystal of racemic acid can be compared with a large package of pairs of gloves; since each pair consists of one right-hand and one left-hand glove, the package as a whole may be considered superposable on its mirror image. These postulates of Pasteur form the basis of the following discussion; their justification lies in the fact that, as is shown below, they permit uniformly correct predictions to be made regarding the properties of, and relationships among, optically active substances.

### III. GENERAL DISCUSSION OF STEREOISOMERISM

**1. Symmetry Elements of Molecules.**—It is desirable at this point to examine the characteristics of a molecule which make it dissymmetric, or prevent its being so, as the case may be.

The symmetry of any rigid body can be described with the aid of its so-called symmetry elements. These elements are of several different kinds, of which only the following need be mentioned here. (1) An object is said to possess a plane of symmetry if a plane mirror can be imagined passing through it so that one half of the object coincides with the reflection in the mirror of the other half. The plane of the mirror is then the plane of symmetry. (2) An object is said to possess an  $n$ -fold axis (or an axis of order  $n$ ) if it possesses an axis, about which rotation by  $360^\circ/n$  brings the object into a position indistinguishable from its original one. The order  $n$  can take on any positive integral value, or it may be infinite if the object has, for example, the symmetry of a right circular cylinder. In general,  $n$  rotations by  $360^\circ/n$  bring the object into a position identical with, and not merely indistinguishable from, the original one. Any straight line passing through any object is clearly a onefold axis; such onefold axes may usually be ignored, however, in discussions of symmetry since an infinite number of them are always present. (3) An object is said to possess a centre of inversion (or of symmetry, or of reflection) if it contains a point within it, such that any straight line through that point encounters exactly the same environment in each of its two directions. Further discussion,

with examples, of each of these types of symmetry element is given in the article CRYSTALLOGRAPHY. A number of additional examples are also mentioned below.

The above-mentioned plane and centre of symmetry are examples of elements with what may be termed reflection symmetry. The most general type of element possessing this kind of symmetry is the so-called alternating (or mirror) axis, of which the plane and centre of symmetry are only special cases. Although no detailed description of alternating axes need be given here, mention should be made of the fact that an object may possess such an axis without having either plane or centre of symmetry. (See below.)

Mathematical analysis has shown that an object is superposable on its mirror image if, and only if, it possesses reflection symmetry of some sort. In stereochemistry, this rule finds its only important applications in those instances in which the molecules have either planes or centres of symmetry, or both. Not until 1955 was there reported (G. E. McCasland and S. Proskow) the preparation of an optically inactive substance with neither of these two symmetry elements, but with a fourfold alternating axis. Accordingly, the statement that a compound must be optically active unless it is a mixture of enantiomorphs (like racemic acid) or else its molecules possess either planes or centres of symmetry is adequate for most purposes. It is especially to be noted that the presence of simple (not alternating) axes of symmetry is not sufficient to ensure optical inactivity; or, in other words, that a molecule may possess an axis of symmetry and still be dissymmetric. (For an example of a dissymmetric molecule with both twofold and threefold simple axes, see the cobalt compound XXXII in the section below, *Elements of Co-ordination Number 6*.)

**2. Enantiomorphs.**—Since enantiomorphs have not only identical structures but also very similar configurations (*i.e.*, atomic arrangements in space), such pairs of substances should possess extremely similar properties. Indeed, in consequence of the mirror-image relationship assumed to exist between enantiomorphs, each property of either enantiomorph must be (in the sense discussed below) the mirror image of the corresponding property of the other enantiomorph; in other words, two enantiomorphs must be identical with respect to all those properties which are themselves (in this same sense) identical with their own mirror images, and can differ with respect to only those other properties which are different from their mirror images. For example, the melting point of any substance may be considered identical with that of its mirror image, since the temperature at which solid and liquid are in equilibrium must be the same whether the experiment is viewed directly or by reflection in a mirror. Consequently, two enantiomorphs must have identical melting points. In a similar way, it can be shown that two enantiomorphs must also have identical vapour tensions at any specified temperature, identical boiling points at any specified pressure, identical densities under the same conditions, identical solubilities in any specified optically inactive solvent, identical rates of reaction with any specified optically inactive reagent (or reagents), identical equilibria in their reactions with any specified optically inactive reagent (or reagents), and so on. On the other hand, the mirror image of a rotation of the plane of polarization by a specified number of degrees to the right (or left) may be considered to be a rotation by exactly the same number of degrees to the left (or right), respectively. Consequently, two enantiomorphs, under identical conditions, must rotate the plane of polarization by equal amounts but in opposite directions. Similarly, the mirror image of right (or left) circularly polarized light is identical not with itself but instead with left (or right) circularly polarized light. Consequently, two enantiomorphs may be expected to possess different optical properties (*e.g.*, absorption spectra, indexes of refraction, etc.) when examined with circularly polarized light, but not when examined with ordinary light or even (except for the optical rotation) when examined with plane polarized light; conversely, the optical properties of a single optically active substance may be expected to be different with right and left circularly polarized light. The expected differences in spectrum have been

observed experimentally (circular dichroism, Cotton effect); and the differences in index of refraction, although so small that their direct observation is difficult, are known always to exist since the observed angle of rotation by an optically active substance can be shown to be proportional to the difference in the indexes of refraction for right and left circularly polarized light. Also, measurable differences have been found in the rates and extents of adsorption (*q.v.*) of enantiomorphs upon optically active solid adsorbents, and in the rates and equilibria of their reactions with optically active reagents (see *Asymmetric Syntheses and Decompositions*, below). Finally, the crystals of two enantiomorphs may be nonsuperposable mirror images of each other (*cf.* the enantiomorphs of tartaric acids and tartrates, above); in many instances, however, the forms of the crystals of enantiomorphs are symmetrical and identical.

**3. Diastereomers.**—Examples of stereoisomers which are not enantiomorphs of each other are well known. In 1853 Pasteur discovered that the cinchonine (see CINCHONA BARK, ALKALOIDS or) salt of either tartaric or racemic acid, when heated for several hours at 170° C., is transformed into the salt of still a different stereoisomeric acid. This acid, known as mesotartaric acid, resembles racemic acid in being optically inactive, but it differs from racemic acid in having a different melting point, different solubilities, etc., and also in not being separable into two enantiomorphs. The individual molecules of mesotartaric acid, therefore, must be symmetrical (*i.e.*, superposable on their mirror images). The substance, although a stereoisomer, is not an enantiomorph, of either of the active tartaric acids.

In subsequent years, a large number of nonenantiomorph stereoisomers have been discovered. An extreme example of this is provided by the aldohexoses (see CARBOHYDRATES), of which the pyranose structure permits no less than 32 stereoisomeric forms, divisible into 16 pairs of enantiomorphs; all are known.

No general term has come to be universally adopted for the description of the relationship between two stereoisomers which are not enantiomorphs of each other. The word "diastereomer" (or diastereoisomer, or diamer) is often applied to certain, but usually not to all, such pairs of substances. For purposes of brevity and convenience throughout the remainder of this article, any nonenantiomorph stereoisomer will be termed a diastereomer. It is to be noted, however, that, in this respect, the present article departs somewhat from the most customary terminology.

Unlike enantiomorphs, diastereomers (in the sense just defined) need not have closely similar physical and chemical properties. Indeed, they may differ as greatly as do structural isomers. For example, either of the optically active tartaric acids melts at 187° C., whereas mesotartaric acid melts at 143° C.

**4. Meso Forms.**—As with the tartaric acids, it frequently happens that a set of stereoisomers contains both optically active and optically inactive members. The inactive members of such sets are frequently distinguished from their active isomers by being called meso forms. (This is, of course, the significance of the name mesotartaric acid.)

**5. Racemic Modifications.**—A mixture of equal quantities of two enantiomorphs, which is optically inactive, is known as a racemic modification. The name is derived from racemic acid, the first example of such a mixture to be carefully studied. (The double use of the word racemic is found in practice to lead to little if any confusion.) Any process by which an optically active substance is transformed into the corresponding racemic modification is known as a racemization; conversely, any process by which a racemic modification is separated into the two enantiomorphs is known as a resolution. (See *Racemization and Resolution*, below.)

In the liquid and gaseous states, a racemic modification seems always to be merely a mechanical mixture of its two components. In the solid state, however, three different situations have been encountered. (1) Sometimes, as with sodium ammonium racemate crystallized from water at a temperature below 28° C. (see above), the solid is a conglomerate (or racemic mixture) consisting of separate crystals of the two enantiomorphs. (2) Sometimes, as with the dimethyl ester (see ESTERS) of a

cemic acid, the two enantiomorphs form a 1:1 compound (or racemate) with each other. Such compounds, however, decompose into their constituents at temperatures above their melting points. (3) Sometimes, as with camphor oxime (see OXIMES), the enantiomorphs form a solid solution (or pseudoracemic mixed crystal).

**6. A Word About Nomenclature.**—Dextrorotatory and levorotatory enantiomorphs were originally designated by the prefixes *d* and *l*, respectively, so that the dextrorotatory and levorotatory tartaric acids, for example, were called *d*-tartaric acid and *l*-tartaric acid, respectively. Somewhat later, however, these prefixes were made to refer also to the so-called optically active series to which the substances belonged, as well as to the directions of rotation. (For the significance of these series, see *Optically Active Series*, below.) As a result of this ambiguity in nomenclature, there were found to be many substances which had to be assigned the prefix *d* because they were dextrorotatory, and, at the same time, the prefix *l* because they belonged to the *l*-series (or the opposite). The confusion which was thus caused has been alleviated to some extent by the adoption of the convention that the prefixes *D* and *L* are used for the designation of the optically active series, and that the further prefixes (+) and (−) are employed to represent dextrorotation and levorotation, respectively.

Unfortunately, the convention just discussed is not always followed consistently by all chemists. If a substance does not belong to any of the accepted optically active series, the prefixes *d* and *l* are often used, as originally, to indicate the direction of rotation. Thus, the naturally occurring levorotatory quinine (*q.v.*) is often referred to as *l*-quinine rather than as (−)-quinine. No confusion can arise in such instances since no *d*- and *l*-series, or *D*- and *L*-series, have been defined for alkaloids like quinine. However, an expression like "*d*-lactic acid" may refer either to the dextrorotatory form, which belongs to the *L*-series (see above), or to its enantiomorph in the *D*-series. Consequently, such an expression is configurationally meaningless, unless accompanied by a statement as to which convention is being employed. In this article, the prefixes *D* and *L* are used to represent the optically active series, and the prefixes (+) and (−) are used to represent the direction of rotation (even for substances like quinine, for which no series have been defined).

Optically inactive meso forms are frequently designated by the prefix *i* (for inactive) or *m* (for meso). Thus mesotartaric acid may be called either *i*-tartaric acid or *m*-tartaric acid. Racemic modifications are similarly designated by the prefix *r* (for racemic) or (±) or DL (to indicate that the compound is a mixture of the two enantiomorphs). Thus, racemic acid may be called *r*-, (±)-, or DL-tartaric acid.

**7. Racemization.**—The ease with which an optically active substance can be transformed into the racemic modification varies within wide limits. On the one hand, the racemization of certain compounds (for example, an optically active paraffin hydrocarbon) is extremely difficult; on the other hand, the racemization of certain other compounds (for example, a tertiary amine, see *Stereochemistry of Nitrogen*, below) is so easily accomplished that the optically active forms cannot be obtained. With innumerable further compounds, however, the ease of racemization lies between these two extremes. Such compounds can be separated (see *Resolution*, below) into the active enantiomorphs, which can then be racemized more or less readily.

The experimental conditions under which the racemization of racemizable substances can be effected also vary widely. In all instances, however, the racemization is presumed to occur as a result of a reversible transformation into an unstable substance which is symmetric and so incapable of optical activity; the reverse transformation back from this hypothetical inactive intermediate then leads to the inactive (*i.e.*, racemic) modification of the original substance.

The transformations which thus lead to racemization are considered most commonly to involve chemical reactions of a familiar type, but occasionally to involve merely geometrical deformations.

**8. Resolution.**—Whenever a substance capable of optical ac-

tivity is prepared under the usual experimental conditions from exclusively inactive reagents, the product obtained is always the inactive racemic modification. This is because, in view of the complete symmetry of the experimental situation, the probability that a molecule of the dextrorotatory enantiomorph will be formed is exactly the same as the probability that one of the levorotatory enantiomorph will be formed. Consequently, equal numbers of molecules of the enantiomorphs must be formed, so that the product must be racemic. If an optically active product is desired instead a resolution must therefore be performed.

The separation of a racemic modification into its two optically active components is made rather difficult by the close similarity of enantiomorphs in nearly all their properties. Two important methods of resolution were developed by Pasteur. The first of these, known as the method of spontaneous separation, has already been described in connection with Pasteur's work on sodium ammonium racemate. It can be employed if the solid racemic modification is a conglomerate composed of observably different crystals. Only a few instances in which this condition is satisfied have been reported in the organic chemical literature. Consequently, this method, although of great historical and theoretical interest, is seldom applicable.

Pasteur's second method of resolution is of much greater generality than his first, and it is the only one commonly used. It is based upon the transformation of the mixture of enantiomorphs into a mixture of diastereomers, which, since they differ in physical properties, can be separated relatively easily. This transformation requires the use of some previously obtained optically active substance. For example, Pasteur showed in 1853 that when racemic acid is treated with a naturally occurring optically active base, such as cinchonine, strychnine, brucine or quinine (see ALKALOIDS), the resulting salt is a mixture of diastereomers and no longer one of enantiomorphs. This is because (if, for definiteness, the base is assumed to be dextrorotatory) the salt formed from the (+)-acid and (+)-base is not the mirror image of the one formed from the (−)-acid and the same (+)-base. (The mirror image would instead be the salt formed from the (−)-acid and (−)-base.) The two salts present in the mixture may, therefore, be expected to have different solubilities and so to be separable by crystallization. After the separation has been carried out, the salt from the (+)-acid and (+)-base gives the pure (+)-acid when treated with a strong mineral acid, and the other salt gives the pure (−)-acid when treated similarly.

In the form just outlined, Pasteur's second method can be applied to the resolution of only racemic acids. Various modifications have been developed, however, and these permit it to be greatly extended. Thus, a racemic base can be resolved by means of salt formation with an optically active acid, a racemic aldehyde or ketone can be resolved by means of hydrazone formation with an optically active hydrazine, and so on. Moreover, a racemic alcohol can be resolved if it is first transformed into the acid ester of a dibasic acid (such as phthalic acid, *q.v.*), which is neutralized as before with an optically active base; the resulting ester salt can then be separated into the diastereomeric forms and finally hydrolyzed back to the alcohol.

Similar schemes of greater or less complexity can be devised for most remaining types of substance.

**9. Asymmetric Syntheses and Decompositions.**—If a compound capable of optical activity is prepared in a dissymmetric environment, the product obtained need not be completely racemic since factors are present which may favour the formation of one enantiomorph over that of the other. Such reactions are known as asymmetric syntheses (although dissymmetric syntheses might seem a more appropriate expression). For example, although the reduction of inactive phenylglyoxylic acid  $C_6H_5-CO-CO_2H$  leads to completely racemic mandelic acid  $C_6H_5-CHOH-CO_2H$ , the reduction of the (−)-menthyl ester of the acid, followed by hydrolysis of the resulting menthyl mandelate gives a mandelic acid which is levorotatory although it contains a considerable amount of the (+)-enantiomorph. This slightly active acid can be separated by crystallization into the optically pure (−)-mandelic acid and *r*-mandelic acid. A different type of asymmetric syn-

thesis is illustrated by the base-catalyzed reaction between benzaldehyde  $C_6H_5-CHO$  and hydrogen cyanide  $HCN$  to give mandelonitrile  $C_6H_5-CHOH-CN$ . Since the reagents are optically inactive, the product is necessarily racemic if the basic catalyst is also inactive; however, if an optically active catalyst, such as the alkaloid quinine, is used instead, the resulting mandelonitrile is somewhat optically active.

The asymmetric syntheses mentioned above are relative, since they require the previous existence of at least one optically active substance. A few absolute asymmetric syntheses, which are not subject to this requirement, have been reported. These syntheses are based upon photochemical reactions (see PHOTOCHEMISTRY) initiated by circularly polarized light; since circularly polarized light is not identical with its own mirror image (see above), it provides the necessary dissymmetric environment.

Asymmetric decompositions, either relative or absolute, can be performed under conditions analogous to those employed with the above asymmetric syntheses.

Asymmetric syntheses and decompositions are of especially great importance in biological reactions, since the reactions which occur in living systems are so frequently brought about by optically active reagents or are catalyzed by optically active catalysts (enzymes). For example, the fact that green plants are able to transform inactive water and carbon dioxide into active carbohydrates (see PHOTOSYNTHESIS) is due to the occurrence of asymmetric syntheses. Similarly, the fact that the natural  $D(+)$ -glucose is easily metabolized by animals and is fermented by yeast, whereas its enantiomorph undergoes neither reaction, must be attributed to the occurrence of asymmetric decompositions. An important application of such biological reactions was discovered by Pasteur, who found (1856-60) that the mold *Penicillium glaucum*, when allowed to grow in the presence of racemic (tartaric) acid, destroys the  $(+)$ -enantiomorph preferentially, so that the acid which remains becomes levorotatory. This method of obtaining optically active substances is of considerable generality since other microorganisms have been found to have similar effects, and since other racemic modifications have been made active in similar ways; it has, however, serious limitations since many substances are not attacked by any known organisms, and since often the organism destroys just the enantiomorph which is desired. It should be noted that the method cannot be called a resolution since one of the two enantiomorphs is always destroyed. (See also CARBOHYDRATES.)

#### 10. The Origin of Optically Active Substances in Nature.

—The frequent occurrence of optically active substances in animal and vegetable sources can be explained only as the result of asymmetric syntheses or decompositions. These reactions are made possible by the presence of pre-existing optically active substances, which must themselves have been made by asymmetric syntheses or decompositions; and so on. If life started on this earth many millions of years ago by the coming together of simple inorganic and optically inactive materials, there must have been a time at which the optical activity began. The question therefore arises how it came into being in the absence of any pre-existing optically active substance. (If life is assumed not to have started on this planet but to have come from some other body, the difficulty is merely pushed back in time and not avoided.) Naturally, the answer to this question is unknown, and possibly unknowable. Scientists have nevertheless speculated about it for many years.

Two types of theory have been advanced to explain the origin of optical activity. The first of these is based upon the fact of spontaneous-separation. It is not inconceivable that an optically active substance produced in small amount in this way may have been involved somehow in the origin of life. An objection raised to this explanation is that it depends too much upon the operation of chance. The supposition that the universal and uniform occurrence of optical activity could have arisen in such a manner seems unlikely a priori.

The second kind of theory is based upon the existence of absolute asymmetric syntheses and decompositions. For example, since light can be circularly polarized by reflection, life may conceivably have started at such a time and place that the first

organisms were more or less constantly subjected to the action of either right or left circularly polarized light. This theory avoids the difficulty of assigning too great a role to chance. It encounters a different one, however, in that the activities producible photochemically in the laboratory have always been extremely small, and also in that the natural circular polarization of light could at most be slight. A further theory, which assumes that the earth's magnetic field produced the necessary dissymmetric environment, enjoys a similar advantage, but it suffers from similar disadvantages.

### IV. THE STEREOCHEMISTRY OF CARBON

**1. The Tetrahedral Carbon Atom.**—The above extremely general considerations require no assumptions in regard to the actual geometrical forms of the molecules under discussion. Such assumptions become necessary, however, if the attempt is made to account for the numbers of stereoisomers corresponding to each structural formula. The first successful theory based upon explicit geometrical assumptions was brought forth simultaneously and independently in 1874 by J. H. van't Hoff and J. A. Le Bel. The ideas of van't Hoff were somewhat more definite than those of Le Bel, but they differed in no respect important to the present article. The following discussion makes no effort to follow either van't Hoff's or Le Bel's development very closely; it attempts instead to present the fundamental principles in logical rather than in historical order.

For the molecular formula  $CH_4$ , only the single structure I can be drawn (if, as usual, carbon and hydrogen are considered to be quadrivalent and univalent, respectively), and only the

single substance, methane, is known. Similarly, for the formula  $CH_3Cl$ , only the single structure II can be drawn, and only the single substance, methyl chloride, is known. Now, if one hydrogen atom in methane were different from any one of the others in any respect, the substance produced by the replacement of the first hydrogen atom by a chlorine atom should be different from the one produced by the replacement of the second hydrogen atom. Consequently, at least two distinct substances,  $CH_3Cl$  should exist. The fact that only one such substance is known strongly suggests, therefore, that all four hydrogen atoms of methane are completely equivalent to each other, not only structurally but also geometrically.

The requirement that all four hydrogen atoms of methane be geometrically equivalent restricts the atomic arrangements to the following: (1) The hydrogen atoms might lie at the corners of a rectangle, with the carbon atom at the centre, as in III. The dotted lines outlining the rectangle are given only for the sake of clarity; they do not represent valence bonds of any kind. This model is known as the planar model. (2) The hydrogen atoms might lie at the corners of the base of a square pyramid, with the carbon atom at the apex, as in IV. (It should be noted that,

if the base of the pyramid were rectangular rather than square, two enantiomorphic forms of each monosubstituted derivative  $CH_3R$  would be possible. Such a configuration can, therefore, be excluded.) The dotted lines are again given only for the sake of clarity. This model is known as the pyramidal model. (3) The hydrogen atoms might lie at the corners of a tetrahedron, with

the carbon atom in the centre, as in V. The dotted lines which outline the imaginary tetrahedron are given, as before, only for the sake of clarity. A more convenient, but equivalent, representation of this so-called tetrahedral model, which is employed throughout the remainder of the article, is shown in the diagram VI. The two broken lines in this latter figure represent valence bonds to hydrogen atoms lying behind the plane of the paper; the two heavy lines represent bonds to hydrogen atoms lying in front of the plane of the paper.

The decision among the planar, pyramidal and tetrahedral models is made possible by a consideration of the numbers of isomeric substances  $\text{CH}_2\text{RS}$ , where R and S represent any two specified, but not necessarily different, atoms or groups. Only one known substance, methylene chloride, exists with the formula  $\text{CH}_2\text{Cl}_2$ ; only one, chloroacetic acid, exists with the formula  $\text{CH}_2\text{Cl}-\text{CO}_2\text{H}$ , etc. For no formula of this type is more than a single substance known. Now, the planar model would lead to the three distinct spatial arrangements or configurations VII, VIII and IX, of which VII and VIII are identical if the rectangle

is a square. Since IX cannot be identical with VII or VIII under any circumstances, however, this model requires the existence of at least two stereoisomeric forms and so can be excluded from further consideration.

The pyramidal model might be expected, like the square planar one, to permit two stereoisomeric substances. Thus, the two configurations X and XI are possible. If R and S are not identical, however, the configuration X is dissymmetric, and so its nonsuperposable mirror image (enantiomorph) XII represents still a third stereoisomer. Since stereoisomerism has never been observed with structures of the present type and, moreover, since optical activity has never been encountered, the pyramidal model must also be incorrect.

Only the tetrahedral model remains. If the tetrahedron is regular, this model permits only a single substance  $\text{CH}_2\text{RS}$ , whether R and S are identical or different. In particular the configuration, as shown in XIII, is symmetrical since it has a plane of symmetry passing through R, S and C, and so no optical activity is possible and no enantiomorphs can exist. The regular tetrahedral model, therefore, reproduces the experimentally observed numbers of isomers.

The regular tetrahedral model is the only one in agreement with the observed numbers of isomers; consequently, it must be assumed correct. Confirmation of this model is provided by the fact that it correctly predicts the occurrence of optical activity, and hence also of enantiomorphs, with substances with the formula  $\text{CPRST}$ , where no two of the atoms or groups P, R, S and T are identical. Lactic acid,  $\text{CH}_3-\text{CHOH}-\text{CO}_2\text{H}$ , for example, occurs

in enantiomorphous dextrorotatory and levorotatory forms. For the molecules of these substances, the nonsuperposable, mirror-image configurations XIV and XV are possible. One of these must therefore represent the molecule of the dextrorotatory lactic acid, and the other must represent that of the levorotatory form. Although it was long uncertain which of these two configurations belongs to each isomer, the problem was finally solved in 1951 by J. M. Bijvoet and his coworkers. By means of a complex and unusual modification of the methods of X-ray crystal-structure analysis, these authors showed that configurations XIV and XV describe, respectively,  $(-)$ - and  $(+)$ -lactic acid.

Physical evidence has confirmed the conclusions reached above. Studies of spectra and of X-ray and electron diffraction have shown that a saturated carbon atom is indeed tetrahedral, in the sense that the four single bonds which it forms are directed toward the corners of a tetrahedron, of which it occupies the centre. (The tetrahedron itself, of course, is only an intellectual construction without physical reality.) Moreover, the tetrahedron has been found to be regular, or very nearly regular, so that the angle between any two of the single bonds formed by the central carbon atom has the so-called tetrahedral value of  $109^\circ 28'$ , or very nearly that value. When the four atoms or groups joined to the carbon atom are of the same kind, as in methane  $\text{CH}_4$  or carbon tetrachloride  $\text{CCl}_4$ , the tetrahedron seems always to be strictly regular, but, when the atoms or groups are not of the same kind, as in methylene chloride,  $\text{CH}_2\text{Cl}_2$ , some small distortions may occur.

**2. Asymmetric Carbon Atoms.**—A carbon atom is said to be asymmetric if it is joined by four different atoms or groups. Thus, of the three carbon atoms in lactic acid, the central one is seen to be asymmetric. (The terminology here is correct since an asymmetric carbon atom possesses no element of symmetry and so is actually asymmetric, and not merely dissymmetric.) The majority of all known optically active substances consist of molecules which contain one or more asymmetric carbon atoms. However, the presence of such atoms is neither necessary nor sufficient for optical activity. As will be discussed below, many substances containing no asymmetric atoms are active. Conversely, many containing asymmetric atoms are inactive. Optical activity arises from the dissymmetry of each individual molecule as a whole; the presence or absence of asymmetric atoms is important only insofar as it determines the symmetry or dissymmetry of the molecule.

**3. The Stereochemistry of Olefinic Compounds.**—Van't Hoff assumed that the carbon atoms in unsaturated compounds have the same tetrahedral form as those in the saturated substances. The configuration of ethylene,  $\text{H}_2\text{C}=\text{CH}_2$ , thus becomes XVI. If this configuration is correct, the six atoms in the molecule

lie in the same plane (the plane of the paper in XVI), the  $\text{H}-\text{C}-\text{H}$  bond angles have the tetrahedral value of  $109^\circ 28'$ , the  $\text{C}-\text{C}-\text{H}$  angles (or, more precisely, the angles between the carbon-hydrogen bonds and a straight line passing through the carbon atoms) are  $125^\circ 16'$ , and the carbon-carbon distance is 0.58 times that in ethane,  $\text{CH}_3-\text{CH}_3$ .

Although erroneous in some respects (see below), van't Hoff's configuration of ethylene appears to be correct in all essential stereochemical details. In particular, it leads to correct predictions of the numbers of stereoisomeric forms of suitably substituted ethylenes. Indeed, its significant features can be deduced directly, and without reference to the tetrahedral carbon atom, from considerations of isomer numbers. For example, with a molecule with the structure  $\text{HRC}=\text{CHR}$ , this planar model permits the two configurations XVII and XVIII. Now, XVII and XVIII must represent optically inactive diastereomers since, with each, the plane of the molecule is a plane of symmetry.

In the particular case in which R is the carboxyl group,  $\text{CO}_2\text{H}$ , two substances, fumaric and maleic acids (*q.v.*), are known; each of these acids is optically inactive, and the two differ markedly

in nearly all their properties (*see above*). Consequently, they must be diastereomers and cannot be enantiomorphs. Since numerous further examples of similar type are known, and since optical activity has never been encountered in substances with the structure  $\text{HRC}=\text{CHR}$  (unless R represents a dissymmetric group), the necessary conclusion is that the planar model is correct, in agreement with van't Hoff. The configuration XVII is commonly said to be *cis* (Lat. *cis*, "on this side"), whereas XVIII is said to be *trans* (Lat. *trans*, "across").

From considerations of isomer number alone, no information can be obtained regarding the values of the bond angles or of the interatomic distances in ethylene and its derivatives; consequently, the angles and distances derived from van't Hoff's configuration, with the tetrahedral carbon atoms, cannot be verified by purely chemical procedures.

Physical investigations (*see SPECTROSCOPY; ELECTRON DIFFRACTION*) have shown, however, that it is precisely in such respects that van't Hoff's model is incorrect. Thus, in ethylene, the  $\text{H}-\text{C}-\text{H}$  and  $\text{C}-\text{C}-\text{H}$  angles are more nearly equal to  $120^\circ$  than to  $109^\circ 28'$  and  $125^\circ 16'$ , respectively; and the carbon-carbon distance is more nearly 0.87 than 0.58 times that in ethane. Moreover, the modern quantum-mechanical picture of the double bond is rather different from that provided by the tetrahedral model XVI. Nevertheless, these defects in no way limit the usefulness of the simple model for the prediction and interpretation of the observed numbers of stereoisomers.

**4. The Stereochemistry of Acetylenic Compounds.**—Just as with ethylene, van't Hoff assumed that the carbon atoms in acetylene,  $\text{H}-\text{C}\equiv\text{C}-\text{H}$ , are tetrahedral. He accordingly wrote the configuration as XIX. This linear model is in agreement with

the observed numbers of isomeric substitution products and also with recent physical evidence. Consequently, although van't Hoff's model of acetylene is inaccurate in several respects (analogous to those in which his model of ethylene is inaccurate, *see above*), it leads always to correct predictions of the numbers of isomers.

**5. Free Rotation.**—Certain limitations must be imposed upon the general statement that two molecules correspond to different substances unless they are exactly alike with respect to the relative positions in space of all their atoms. For the structure  $\text{H}_3\text{C}-\text{CH}_3$ , for example, an infinite number of geometrical arrangements (or conformations) are consistent with the assumption of tetrahedral carbon atoms; these include the two represented by XX and XXI, as well as all the further ones obtainable from

either XX or XXI by rotation of one  $\text{CH}_3$  group with respect to the other about the carbon-carbon bond. If each of these

conformations represented a distinct substance, then an infinite number of stereoisomers with the structure in question should exist. Only a single substance, ethane, is known however. Similar considerations apply to nearly all further structures in which multivalent atoms are joined by single bonds. It is evident, therefore, that, if the geometrical interpretation of stereoisomerism is to be maintained, some further assumption, which restricts the predicted numbers of isomers, is required.

The assumption generally adopted for this purpose is contained in the rule that any two conformations (such as XX and XXI, or any other two of the infinite number of possible ones) are to be considered equivalent if they differ only by the rotation of one or more parts of the molecule about one or more single bonds. Thus, XX, XXI, etc. are equivalent; all these conformations correspond to the same substance, ethane, and all are said to represent the same configuration. Although this rule has a number of exceptions (*see Optically Active Biphenyls*, below), it is sufficiently general to find application throughout the entire field of stereochemistry. It has indeed already been assumed implicitly at several points of the preceding discussion, and it is assumed hereafter throughout the following discussion without further comment (except in those instances in which it is invalid).

A common alternative statement of the above rule is that rotation about single bonds is free. The use of the term "free rotation" suggests that, in ethane for example, no forces operate to make any one conformation more stable than any other, so that each molecule of the substance spends equal fractions of its time in each of its possible geometrical arrangements. This interpretation is obviously consistent with the fact that stereoisomeric forms of ethane, differing by rotation about the carbon-carbon bond, do not occur; nevertheless, it is probably incorrect. From a combination of spectroscopic and thermochemical data, the conclusion has been drawn that the "eclipsed" conformation XX is less stable (*i.e.*, has a higher energy) than the "staggered" one XXI by about 3,000 cal. per mole. If this conclusion is correct, most of the molecules at any one time must have arrangements rather close to the staggered one XXI. Stereoisomerism is still impossible, however, since each molecule must spend part of its time in each of the conformations, and since the transition from any one conformation to any other is rapid and easy.

In nearly all other substances for which data are available, the situation seems to be similar to that in ethane. Certain conformations always seem to be appreciably more stable than others differing from them by rotation about one or more single bonds, but stereoisomers are not encountered because the transition from one conformation to another is easy. In general, stereoisomers can be expected to occur only if there are two or more essentially different geometrical arrangements of the atoms, and if transitions between these arrangements are not easy. A transition may be considered easy at ordinary temperatures if it can be undergone by a molecule possessing an energy much less than about 20,000 cal. per mole above the average. This is because, as a result of the statistical variations in energy (*see KINETIC THEORY OF MATTER*), the number of molecules possessing the required excess energy is then sufficiently great to permit an appreciable rate of interconversion; consequently, the separation of the isomers would be difficult or impossible. Stereoisomerism is, therefore, impossible in ethane, since a molecule of this substance requires an excess energy of only approximately 3,000 cal. per mole for a complete rotation of  $360^\circ$  about the carbon-carbon bond. On the other hand, the existence of the stereoisomeric maleic and fumaric acids, to which the configurations XXII and XXIII, respectively, have been assigned, shows that only such

molecules as possess at least 20,000 cal. per mole of excess energy can undergo the transition. Just as the nonexistence of stereoisomers in ethane (and the like) is attributed to the freedom of

rotation about the carbon-carbon single bond, so also the existence of stereoisomerism between maleic and fumaric acids (and the like) is attributed to the lack of free rotation about the double bond.

It is interesting that van't Hoff's models of ethane and ethylene (XX and XVI, respectively) are consistent with the presence of free rotation about the single bond and the lack of it about the double bond. Since the two carbon atoms in ethane are joined by just one linkage, no forces exist in the model XX to favour any one conformation over any other. Consequently, rotation might be expected to be easy in the molecule also. On the other hand, since the two carbon atoms in ethylene are joined by two bonds, the model XVI is held rigidly in the planar form. Consequently, rotation might be expected to be impossible in the molecule. The modern quantum-mechanical pictures of the single and double bonds are rather different from those provided by the models of van't Hoff, but they are equally in agreement with the observed freedom and restriction, respectively, of rotation.

**6. Plane Projection Diagrams.**—The use of three-dimensional models of the sort employed by van't Hoff becomes extremely cumbersome if the molecule to be represented is even moderately complicated. Moreover, such models cannot be depicted very conveniently on a plane surface, such as a printed page; even the relatively simple diagrams XX and XXI, for example, are not too easily intelligible, and the situation rapidly becomes worse as the complexity of the molecule increases. Consequently, some simpler method of representation is highly desirable.

It has become conventional to represent the three-dimensional models by what are called plane projection diagrams or, more simply, plane configurations. Thus, by definition, the diagrams XXIV and XXV represent the dextrorotatory and levorotatory forms,

respectively, of glyceraldehyde. It is to be noted that these diagrams do not in themselves specify the absolute configurations (i.e., the true three-dimensional forms of the actual molecules). The diagram XXIV, for example could be considered the projection of either XXVI or XXVII; similarly, XXV can be considered the projection either of XXVIII (identical with XXVII) or of its enantiomorph XXIX (identical with XXVI). Nevertheless, the

work of Bijvoet *et al.* (see above) has shown that the plane configurations XXIV and XXV actually correspond to the absolute configurations XXVII and XXIX, respectively.

The usefulness of plane configurations like XXIV and XXV lies in the fact that they make possible the unique representation of relative configurations. In other words, the plane projection diagrams define the configurations of the substances to which they refer by comparing them with those of the glyceraldehydes. Since the absolute configurations of the glyceraldehydes are now known, the relative configurations of other substances define the absolute ones.

Considerable care must be exercised in the use of the plane configurations, since errors and inconsistencies can easily be introduced. It might appear, for example, that the diagrams XXIV and XXV are identical since a rotation of  $180^\circ$  about a vertical axis lying in the plane of the paper would transform either into

the other. Consequently, if XXIV and XXV are to represent enantiomorphs, a rotation which takes the figure out of the plane in which it is drawn must be considered to invert the configuration (i.e., to change it into that of the enantiomorph). Although a rotation of  $180^\circ$  out of the plane of the paper inverts the configuration, as stated above, any rotation within the plane of the paper leaves the configuration unchanged. Thus, XXX, XXXI and XXXII are equivalent to XXIV and, like it, represent dextrorotatory glyceraldehyde.

It is to be noted that freedom of rotation does not in general exist about the single bonds in plane projection diagrams of the present type (see *Free Rotation*, above). This is because a rotation about any bond in such a diagram requires that that part of the diagram which is rotated leave the plane of the paper. If this part is dissymmetric, then, according to the convention adopted, it is inverted in the process, so that the resulting configuration is not equivalent to the original one. For example, a rotation by  $180^\circ$  of the lower part of XXIV about the upper carbon-carbon bond changes this configuration into the enantiomorph one XXV. (The  $\text{CH}_2\text{OH}$  group is not affected by the rotation since it is symmetric and so identical with its own mirror image.) These remarks do not imply any corresponding lack of freedom of rotation about the single bonds in the actual molecules or in the three-dimensional models; they have reference instead only to the conventions which must be adopted if the plane configurations are not to lead to self-contradictions.

If a molecule contains a ring of atoms, its configuration may be expressed on a plane surface in either of two ways. When one of these methods is used, the diagram is written as if no ring were present, and then the fact that a ring is present is indicated, more or less as an afterthought, by the drawing in of the necessary bonds as long, and frequently curved, lines. Thus, the configuration of  $\alpha$ -D-glucose (see CARBOHYDRATES) is often written as XXXIII. When the second method of representation is employed, the ring is drawn as if it were a plane polygon approximately at right angles to the plane of the paper, and the substituents attached to the ring atoms are represented by the appropriate symbols above and below the plane of the ring. Thus, the configuration of  $\alpha$ -D-glucose can be written as XXXIV; this diagram is to be considered equivalent to XXXIII. Plane projection dia-

grams like XXXIV do not imply knowledge of the corresponding absolute configurations. A molecule of glucose in which the upper horizontal line (of XXXIV) is in front of the paper, and the lower line is behind it, would be the enantiomorph of a molecule in which the upper line is behind the plane of the paper, and the lower line is in front of it. Nevertheless, since determination of the absolute configurations of the glyceraldehydes (see above) has shown that the hydrogen atoms and hydroxyl groups which are joined to the asymmetric carbon atoms lie in front of the plane of the paper in diagram XXXIII, consistency requires that the lower horizontal

line of XXXIV be in front of, and that the upper horizontal line be behind, the paper. These diagrams do not imply that the rings are completely planar (see *Strain Theory*, below); they imply rather that the average positions of the atoms of the ring lie within a single plane.

The representation of an ethylenic compound is relatively easy since the two carbon atoms joined by the double bond, and the four other atoms joined by single bonds to these two, lie in the same plane. Consequently, diagrams like XXII and XXIII for maleic and fumaric acids, respectively, represent the absolute configurations. Such diagrams need no further discussion.

If a molecule contains several rings, several double bonds, or both rings and double bonds, the representation of its configuration may be rather difficult. In such instances, the conventional scheme just outlined often must be supplemented by the use of heavy and broken lines to represent bonds to atoms in front of and behind the paper, respectively, or by other devices analogous to those employed in preceding sections of this article. Examples of such molecules are given below.

**7. Use of Plane Projection Diagrams for the Prediction of the Number of Stereoisomers.**—The foregoing rather general considerations can be made more definite by a discussion of some specific examples of stereoisomerism. The dextrorotatory and levorotatory glyceraldehydes are represented by the diagrams XXIV and XXV, as has already been mentioned. That these two diagrams correspond to enantiomorphs is shown (according to the conventions adopted) by the fact that each can be considered identical with the reflection of the other in a mirror which is halfway between them and perpendicular to the plane of the paper. Since there is only one asymmetric atom in the molecule, and no further source of molecular dissymmetry, these two enantiomorphs are the only possible stereoisomeric forms.

A molecule of tartaric acid,  $\text{HO}_2\text{C}-\overset{*}{\text{CHOH}}-\overset{*}{\text{CHOH}}-\text{CO}_2\text{H}$ , has two asymmetric carbon atoms (the two designated by asterisks). Since there are two possible configurations about each such atom, one might anticipate altogether  $2 \times 2$ , or 4, distinct stereoisomers, which could be represented by the diagrams XXXV–XXXVIII. Of these, however, the first two are equivalent inasmuch as either is transformed into the other by a rotation

of  $180^\circ$  in the plane. Since these two equivalent diagrams are mirror images of each other, they must represent a substance which is identical with its own mirror image, and so optically inactive; they are, therefore, equivalent forms of the plane configuration of mesotartaric acid (see above). The optical inactivity of this substance follows also from the presence of a plane of symmetry in either of the two diagrams (i.e., from the fact that the upper half of either diagram is identical with the reflection of the lower half in a mirror perpendicular to both the plane of the paper and the central carbon-carbon bond). On the other hand, the last two configurations, XXXVII and XXXVIII, are not equivalent since neither can be transformed into the other by any rotation in the plane. Since they are mirror images of each other, they must be enantiomorphs, and so one must represent the dextrorotatory, and one must represent the levorotatory, tartaric acid. In a way which cannot be described in this article, XXXVII has been shown to belong to the dextrorotatory enantiomorph, and XXXVIII has been shown to belong to the levorotatory one. Thus, the existence of the three known tartaric acids can be explained.

The trihydroxyglutaric acids,  $\text{HO}_2\text{C}-\overset{*}{\text{CHOH}}-\overset{*}{\text{CHOH}}-\overset{*}{\text{CHOH}}-\text{CO}_2\text{H}$ , have the three asymmetric carbon atoms marked by

asterisks. (The central carbon atom may appear not to be asymmetric since two of the groups attached to it are structurally identical. It is customary, however, to regard such atoms as asymmetric since the attached groups may differ in configuration.) Atoms of this type are sometimes said to be pseudoasymmetric. One might expect  $2^3$ , or eight stereoisomeric forms, but, as with the tartaric acids, the number is reduced somewhat by the occurrence of meso forms. Only the four nonequivalent configurations XXXIX–XLII can be drawn, and, in agreement with prediction, only four stereoisomeric substances are known. It is easily seen that XXXIX and XL represent two different meso forms since each has a plane of symmetry (passing through the central CHOH group and perpendicular to the paper), and that XLI and XLII represent a pair of enantiomorphs.

The aldohexoses (see CARBOHYDRATES) have five asymmetric atoms in the pyranose structure (cf. the configurations XXXIII and XXXIV of  $\alpha$ -D-glucose). Since no meso forms are possible,  $2^5$ , or 32, different optically active stereoisomers should exist. As has already been mentioned, all these forms are known.

The cyclohexane-1,2-dicarboxylic acids, like the tartaric acids, contain two equivalent asymmetric carbon atoms; consequently, they also exist in two enantiomorphous forms, XLIII and XLIV, and one meso form XLV. It is readily verified that the configurations XLIII and XLIV are mirror images of each other, and that neither possesses a plane or centre of symmetry. On the other hand, XLV has a plane of symmetry perpendicular both to the ring and to the bond joining the two asymmetric atoms; it is, therefore, identical with its mirror image.

The isomerism of the cyclohexane-1,2-dicarboxylic acids (as well as that of other analogous cyclic compounds) is frequently described by the statement that the optically active forms XLIII and XLIV are trans, whereas the meso form XLV is cis. This nomenclature is convenient since it expresses clearly and concisely the relative positions of the substituent groups with respect to the plane of the ring. However, it has given rise to much confusion since it suggests a false analogy with the cis-trans isomerism in ethylenic compounds like maleic and fumaric acids (see above). In cyclohexane-1,4-dicarboxylic acid, cis and trans forms again exist. Here, however, both the cis form XLVI and the trans form XLVII have planes of symmetry and so are optically inactive. The isomerism of these two substances (like that of the 1,2-di-

carboxylic acids) is not due to the rigidity of the ring; no conceivable rotation about any bond or bonds in the ring could

XLVI

XLVII

transform either isomer into the other, even if the ring were perfectly flexible.

Alanine anhydride (dimethyldiketopiperazine), with a six-membered ring, exists in cis and trans forms. Here, the trans form XLVIII has a centre of symmetry (at the centre of the ring) and

XLVIII

so it is optically inactive. (The presence of the centre of symmetry is apparent if the ring in XLVIII is visualized as lying in a plane perpendicular to that of the paper.) The cis form has neither plane nor centre of symmetry, and so it exists in the two enantiomorphic forms XLIX and L.

XLIX

L

**8. Optically Active Allenes and Their Analogues.**—Van't Hoff pointed out that, if his tetrahedral model of the double bond (see above) is correct, the two  $\text{CH}_2$  groups in allene,  $\text{H}_2\text{C}=\text{C}=\text{CH}_2$ , should lie in planes which are at right angles to each other; and that a substance with the structure  $\text{RSC}=\text{C}=\text{CRS}$ , where R and S are any two different atoms or groups, should exist in the enantiomorphic forms LI and LII. It was not until 1935, however,

LI

LII

that this prediction was verified by P. Maitland and W. H. Mills, who obtained the optically active diphenyldi- $\alpha$ -naphthylallene LIII. In the same year, E. P. Kohler, J. T. Walker and M. Tishler reported the preparation of the similar optically active allene LIV.

LIII

LIV

It is of interest that neither of these substances contains an asymmetric atom.

Although the existence of optically active allenes was not confirmed until comparatively recently, several analogous substances have been known for a longer time. These substances may be considered related to the allenes proper by the replacement of one or both of the two-membered rings (i.e., double bonds) by larger rings. Two typical pairs of enantiomorphs are represented

by the configurations LV and LVI, and LVII and LVIII. As with the allenes, none of these substances contains an asymmetric atom.

LV

LVI

LVII

LVIII

**9. Optically Active Biphenyls.**—In 1922 G. H. Christie and J. Kenner found that the dinitrodiphenic acid LIX can be separated into a pair of enantiomorphs. The present interpretation of this fact is that the molecules of the two substances have the configurations LX and LXI. The two rings here are considered to lie in approximately perpendicular planes. Since a rotation of  $180^\circ$  about the central carbon-carbon bond would transform either enantiomorph into the other, such rotation must be assumed to be impossible. The factor responsible for this restriction of rotation is presumed to be the size of the four substituents attached to the rings. In order for a molecule to pass from one enantiomorphic form to the other, it must, at some time during

LIX

LX

LXI

the process, assume a configuration in which the two rings are coplanar; if this should happen, however, the substituent groups mentioned would be forced to come so close together that they would get in one another's way. In other words, it is difficult, or impossible, for the large nitro and carboxyl groups to slip past each other.

As with the allenes and their analogues, neither this substance nor any of the numerous other ones similar to it possesses an asymmetric atom.

**10. Optical and Geometrical Isomerism.**—Stereoisomerism is often subdivided into optical and geometrical isomerism. The distinction between these two types of isomerism does not appear to be so significant as when it was first introduced; nevertheless, it has been retained by most chemists for historical reasons. A simple and precise definition of optical and geometrical isomerism appears to be impossible. On the one hand, many pairs of substances must be considered both optical and geometrical isomers of

each other at the same time; and, on the other hand, there is no complete unanimity as to exactly where the dividing line between these two types of isomerism is to be drawn.

A typical example that is usually classified as illustrating geometrical isomerism is provided by maleic and fumaric acids, to which, as was stated above, the configurations XXII and XXIII, respectively, have been assigned. The characteristic feature of

these two substances which is of interest here is that, as a result of the rigidity of the double bond, the two carboxyl groups, the two remaining carbon atoms and the two remaining hydrogen atoms are held in the same plane. In many other instances also, two stereoisomers are said to be geometrical isomers of each other if they differ only in the relative positions in space of six coplanar atoms or groups of atoms. (With certain nitrogen compounds, either one or two of these atoms or groups may be missing. See *Stereochemistry of Nitrogen*, below.)

**11. Walden Inversion.**—In 1893, P. Walden discovered the cycle of reactions indicated below:

Thus, by treating either of the optically active malic acids first with phosphorus pentachloride (in chloroform solution) and then with silver oxide (in aqueous solution), he was able to transform it into its own enantiomorph; similarly, by treating either of the active chlorosuccinic acids first with silver oxide and then with phosphorus pentachloride, he was able to transform it also into its enantiomorph. (In each sequence of reactions, considerable racemization occurs, so that the activities of the final products are not great. In other similar sequences that have been discovered subsequently, however, relatively little racemization occurs.)

It is evident that, in one (and only one) reaction of the two in each of these sequences (*i.e.*, in either the reaction with silver oxide or the one with phosphorus pentachloride, but not in both), the entering substituent at the asymmetric atom does not take up the same relative position in space as that formerly occupied by the substituent which it replaces. The change in configuration which thus results is called an inversion or, more precisely, a Walden inversion. (The expression Walden inversion was introduced by E. Fischer in 1906. Originally it referred to the complete sequence of reactions by which the optically active substance is converted into its enantiomorph, and not to the single reaction in which the inversion of configuration occurs. Later, however, the expression seems more usually to refer to the single reaction; it is so used in this article.) The problem of identifying the particular reaction in which the inversion occurs is a difficult one. From evidence which cannot be described here, however, it has been shown that inversions occur in the reactions of the above scheme in which phosphorus pentachloride and potassium hydroxide participate, but that there is retention of configuration in the ones with silver oxide. It is to be especially noted that the fact that the sign of rotation changes in the first two types of reaction but not in the last is purely accidental; the sign of rotation often changes in reactions which are considered to proceed with retention of configuration, and, conversely, it often remains the same in reactions which are considered to proceed with inversion. No necessary general relation exists between the configurations and signs of rotation of nonenantiomorphous substances.

With relatively few exceptions every reaction in which one substituent atom or group is replaced by another is believed to be

accompanied by an inversion of configuration about the atom at which the replacement occurs. Reactions, like that between chlorosuccinic acid and silver oxide, in which no net inversion is considered to occur, are interpreted as proceeding in two steps, with an inversion in each; two inversions, of course, are equivalent to a retention. No inversion is considered to occur at atoms at which no substitution takes place.

A probable mechanism of the Walden inversion is shown schematically in fig. 2. In fig. 2(A), representing an early stage of the reaction, the reagent R approaches the carbon atom from the side opposite the substituent S; in fig. 2(B), representing the mid-point of the reaction, the atoms or groups R and S are equidistant from the carbon atom, which is no longer tetrahedral; and in fig. 2(C), representing the conclusion of the reaction, the displaced substituent S is departing, and the entering one R has become attached to the carbon atom. In the process, the molecule has been "turned inside-out" like an umbrella in a high wind.

FIG. 2.—A PROPOSED MECHANISM OF THE WALDEN INVERSION  
(A) An early stage; (B) mid-point; (C) conclusion

**12. Optically Active Series.**—The sign of the rotation produced by an optically active substance can occasionally be reversed by a change in the experimental conditions (see *Specific Rotation*, above). A further factor which introduces confusion into stereochemical classification is that a parent substance often gives derivatives of identical configuration but with opposite sign of rotation. For example, the salts and esters of the levorotatory lactic acid,  $\text{CH}_3-\text{CHOH}-\text{CO}_2\text{H}$ , are dextrorotatory; those of the dextrorotatory acid are levorotatory. For these reasons, it would seem desirable to include in the complete name of an optically active substance a symbol which refers directly to the configuration of the substance and is independent of the sign of rotation. This symbol would then remain unchanged when the substance, under different conditions, exhibits different signs of rotation, or when it forms derivatives of opposite rotation.

It may be doubted whether any completely general and completely unambiguous classification of configurations of the type desired is possible; certainly, no such classification has as yet been devised. Nevertheless, a scheme has been developed which permits the classification of configurations (but not without some ambiguity) within certain narrowly defined groups of compounds. This scheme consists in dividing configurations into those of the so-called D-series and those of the L-series on the basis of the genetic relationships among them. A substance is then said to belong to the D-series (or to the L-series) if it is a derivative of a substance belonging to the D-series (or L-series), respectively, and so on.

In order that an optically active series may be set up, some particular substance must be defined as belonging to the D- or L-series, so that the remaining substances may be related to it. Originally, Emil Fischer chose the naturally occurring sugars and their derivatives as the prototypes of the series. Later, the glyceraldehydes, XXIV and XXV, were chosen instead (M. A.

Rosanoff, 1906); the two conventions lead to the same assignment of series, so that no ambiguity results.

The way in which the optically active series are built up can be illustrated by a few examples. As has been mentioned before

(+)- and (-)-glyceraldehyde are by definition assigned the configurations XXIV and XXV, respectively. Also by definition, they are said to belong to the D- and L-series, so that their complete names are D(+)- and L(-)-glyceraldehyde, respectively. By well-known methods (see CARBOHYDRATES), the aldehyde group (CHO) of each of these substances can be changed into a CHOH-CHO group. Since this larger group contains an asymmetric carbon atom not present in the original, each of the glyceraldehydes can give rise to two products (which, not being enantiomorphs, need not be formed in equal amounts). Thus D(+)-glyceraldehyde gives rise to LXII and LXIII, which are, therefore, said to belong to the D-series. Similarly, L(-)-

glyceraldehyde gives rise to LXIV and LXV, which are said to belong to the L-series.

The procedure can be continued further. Each of the tetroses LXII-LXV can be transformed into two pentoses, each of which can in turn be transformed into two hexoses, and so on. In each reaction, the two products belong to the same optically active series as the substance from which they were made. In general, and without explicit reference to the sequence of reactions starting with the glyceraldehydes, the optically active series to which any monosaccharide belongs may be said to be determined by the configuration about the asymmetric carbon atom farthest removed from the carbonyl group (C=O); when the chain of carbon atoms is written vertically and with the carbonyl group at the top, the hydroxyl group upon the atom in question is to the right of the chain in the D-series, and to the left in the L-series.

If the glyceraldehydes are oxidized, they give the glyceric acids LXVI and LXVII. The first of these, even though it is levorota-

tory, is said to belong to the D-series because of its genetic relationship to D-glyceraldehyde, it is accordingly called D(-)-glyceric acid. Similarly, the substance LXVII is called L(+)-glyceric acid.

With the  $\alpha$ -amino acids, and frequently also with the  $\alpha$ -hydroxy acids, the optically active series to which a given substance is assigned is determined by the configuration of the carbon atom adjacent to the carbonyl group, and not by that of the one farthest from this group. The two conventions are distinguished by the subscripts *s* and *g* which refer, respectively, to the simple amino acid serine,  $\text{HO}-\text{CH}_2-\text{CN}(\text{N}+\text{H}_3)-\text{CO}_2^-$ , and to the simple sugar, glyceraldehyde XXIV (or XXV). For example, the substance with configuration LXVIII may be described either as D<sub>s</sub>- or as L<sub>g</sub>-trihydroxybutyric acid.

cyclic compounds with only carbon atoms in the ring, or rings) contained either five- or six-membered rings. To explain this fact, he brought forth a group of ideas now called the strain theory. The angle between any two single bonds formed by a saturated carbon atom had been postulated by van't Hoff to have the tetrahedral value of  $109^\circ 28'$  (see above). Consequently, Baeyer considered that an angle of this magnitude is most stable, so that, if one or more angles in a molecule were forced in some way to have a widely different value, the molecule would be "strained," and, therefore, unstable. Now, in cyclopropane LXIX, the C-C-C angles of the three-membered ring must be equal to  $60^\circ$ ; since this value is much smaller than the preferred  $109^\circ 28'$ , the molecule is strained. Thus, Baeyer considered that the difficulty of preparing such a substance is accounted for. Similarly in cyclobutane LXX, the angles would have to be equal to  $90^\circ$  if the four-membered ring is planar; again considerable strain is present, and again the difficulty of preparing the substance appears to be explained. The minimum strain is reached with cyclopentane LXXI, in which the planar ring requires bond-angles of  $108^\circ$ , almost identical with the tetrahedral value. With still larger rings, the strain increases regularly with the size if, as before, the rings are considered to be planar. The six-membered ring of cyclohexane LXXII requires an angle of  $120^\circ$ , the seven-membered ring of cycloheptane requires one of  $128^\circ 34'$ , and so on. Thus,

the least strain occurs in just those rings which are easiest to prepare and best known.

Baeyer's original ideas, although still considered essentially correct, have undergone extensive modification (H. Sachse, 1890). The strain postulated by Baeyer apparently exists only in the three- and four-membered rings, but no strain exists in the rings of six or more atoms. With the small rings, the least strain results if the rings are planar as assumed by Baeyer, but, with the larger rings, the strain can be relieved completely if the ring is permitted to be puckered. With cyclohexane, for example, two different strain-free configurations are possible; these are shown in LXXIII (the so-called boat-form or C-form) and LXXIV (the so-called chair form or Z-form). Transitions among the various

forms of these puckered rings are so easy that isolation of stereoisomeric substances, differing only in the form of the ring, is impossible.

The assumption that the rings with six or more atoms are puckered and strain-free permits the conclusion that such large rings should be as stable as those with five atoms, and, in fact, as stable as the noncyclic chains. This conclusion is verified experimentally. There is no significant difference, referable to strain, between, say, cyclotriacontane, with 30 atoms in the ring, and cyclopentane, with only 5; nor is there any significant difference between either of these substances and any of the typical paraffin hydrocarbons (see PARAFFIN HYDROCARBONS). In particular, neither ring can be broken easily by ordinary chemical reagents, and the heats of combustion of the two cyclic substances (see THERMOCHEMISTRY), per  $\text{CH}_2$  group, are practically identical. (In contrast, the three-membered ring in the strained cyclopropane LXIX is easily broken by reagents like bromine, hydrogen in the presence of a platinum catalyst, and hydrogen chloride,

**13. Strain Theory.**—In 1885 A. Baeyer called attention to the fact that nearly all the then known carbocyclic compounds (*i.e.*,

which have no similar effects upon cyclopentane, cyclotriacontane, or a paraffin hydrocarbon; and the heat of combustion of cyclopropane, per  $\text{CH}_2$  group, is appreciably higher than that of either cyclopentane or cyclotriacontane.)

The reason that Baeyer was misled into believing the large rings to be strained was that, experimentally, such rings are difficult to prepare. More recently this fact has been interpreted differently. The difficulty of preparing cyclotriacontane, for example, is explained as the result, not of any assumed instability of the product, attributable to strain, but rather to the improbability that the two ends of a chain of 30 carbon atoms will happen to come close enough together to permit being joined to each other by a bond. The relative ease of forming the five-membered ring in cyclopentane, on the other hand, is attributed to the relatively great probability that the ends of a much shorter chain of only five carbon atoms will come close enough. In other words, the fact that the five- and six-membered rings are the most easily formed of all is explained as the result of two opposing effects: the strain, which operates against the formation of three- and (to a lesser extent) four-membered rings; and the probability factor, which causes the ease of formation to decrease more or less regularly as the size of the ring increases.

An important service performed by the strain theory consists in providing a reasonable explanation of the nonexistence of certain substances. For example, cyclopropyne LXXV is unknown although, as far as the ordinary rules of valence are concerned, it would appear to be a perfectly reasonable substance. However, if it existed, it would be extremely strained since the normal value of  $\text{C}-\text{C}\equiv\text{C}$  bond angles is  $180^\circ$ . Similarly, cyclohexene might be expected to be obtainable in cis and trans forms, analogous to maleic and fumaric acids, respectively. Only the cis form LXXVI is known; the trans form LXXVII would be too highly strained to be capable of existence. Moreover, camphor LXXVIII

(see CAMPHOR) has the two asymmetric carbon atoms marked with the asterisks. Since these atoms are nonequivalent, meso forms are impossible, and so two pairs of enantiomorphs might be expected. Only one such pair is known. This is the one in which the attachment of the  $-\text{C}(\text{CH}_3)_2-$  "bridge" to the outer six-membered ring is cis; the second pair of enantiomorphs, in which the attachment is trans, would be too strained to be capable of existence.

**14. Conformational Analysis.**—If the chair configuration LXXIV of cyclohexane is written more fully as LXXIX, the hydrogen atoms are seen to be of two geometrically different types. Six of these atoms are joined to the carbon atoms by bonds which are parallel to one another and perpendicular to the average plane of the ring; these atoms and bonds are commonly described as axial. On the other hand, the remaining six hydrogen atoms are joined to the carbon atoms by bonds which lie approximately in the average plane of the ring; these atoms and bonds are commonly described as equatorial.

If one of the hydrogen atoms of cyclohexane is replaced by a substituent, which may be explicitly a methyl group, a halogen atom, or the like, two conformations consistent with the Z-form

of the ring (see above) are possible inasmuch as this substituent may occupy either an axial or an equatorial position. Usually, however, the equatorial position is favoured because it permits the widest possible separation of the atoms that are not bonded to each other.

It will be possible here only to mention, without discussion, two of the many important applications of conformational analysis, which have been made since about 1950. (1) With a disubstituted cyclohexane, cis and trans isomers (see above) are possible. Of these, the trans form is usually the more stable when the substituents are either 1,2 or 1,4 with respect to each other, but the cis form is usually the more stable when the substituents are 1,3 to each other. The reason for these generalizations is that the favoured configurations are the ones permitting the maximum numbers of equatorial substituents. (2) When two or more saturated six-membered rings are fused together, as in decahydronaphthalene, the steroids and numerous other compounds, the molecules are often more or less rigid, so that substituents in given positions are required to be either axial or equatorial. The conformations of the substituents, determined in this way, have been related to the relative stabilities of stereoisomeric forms and to the observed differences in reactivity.

**15. Steric Hindrance.**—The rate of a chemical reaction is often decreased by the presence of nearby bulky substituents. For example, the esterification (see ESTERS) of benzoic acid (*q.v.*) becomes very slow if methyl groups, bromine atoms, or the like are introduced into the positions adjacent to the carboxyl group. This regularity is not limited to esterifications but is encountered throughout organic chemistry; an explanation for it was proposed by F. Kehrman (1888) and by V. Meyer (1894). According to these authors, the substituents fill up the available space about the reactive centres and so make more difficult the approach of the reagent molecules.

This picture, although it clearly appears to contain important elements of validity, is far from complete, and undoubtedly represents a substantial oversimplification. Specific interactions of an electrostatic nature, effects attributable to resonance phenomena (see RESONANCE, THEORY OF), and so on, also would have to be taken into account in any complete treatment of the relation between structure and reactivity.

## V. THE STEREOCHEMISTRY OF NITROGEN

The general principles essential to the understanding of the stereochemistry of the elements other than carbon differ in no significant respect from those essential to the understanding of the stereochemistry of carbon itself. Since these principles are described in considerable detail in the preceding sections of this article, they need not be discussed further here. Moreover, since the factual material relating to the stereochemistry of the remaining elements is relatively restricted (although rather extensive in an absolute sense), a brief survey of the field is sufficient to bring out the important features.

In all optically active compounds known up to 1899, the molecular dissymmetry was dependent upon the spatial arrangement of the valencies of carbon. In that year, however, W. J. Pope and S. J. Peachey discovered that quaternary ammonium salts of the type  $[\text{NQRZ}]^+\text{X}^-$  (where Q, R, T and Z represent four dis-

similar hydrocarbon radicals) could be resolved into enantiomorphs, and hence that the valency configurations of other elements besides carbon could have sufficient permanence to make their stereochemical investigation possible. (J. A. Le Bel had stated earlier that he had obtained an optically active substance of this type, but his work was shown to be incorrect.) Thus a wide field of research was opened. Further work on quaternary ammonium salts showed: (1) that, since molecular dissymmetry could no longer be demonstrated when two of the hydrocarbon radicals were identical, the ion  $[NQRRT]^+$  probably has a plane of symmetry (no centre of symmetry is possible here, whatever the configuration about the nitrogen atom may be); and (2) that, since different methods of formation of a given salt, for instance  $NQRT + ZX \rightarrow [NQRTZ]^+X^- \leftarrow NRTZ + QX$ , never yielded isomeric modifications, the valencies linking the four hydrocarbon radicals to the nitrogen atom are most probably equivalent. Only two configurations of the ammonium ion satisfy these conditions, namely, the pyramidal configuration I and the tetrahedral configuration II; of these, the first has been definitely disproved by W. H. Mills and E. H. Warren (1925).

The amine oxides are another class of compound in which a nitrogen atom forms bonds to four distinct other atoms or groups. In these also, the radicals appear to be tetrahedrally disposed about the nitrogen atom, for amine oxides of the type III have been obtained in optically active forms by J. Meisenheimer (1908).

The configuration of the trivalent nitrogen atom is of special interest because of the number and importance of the compounds in which the element is present in this state. The numerous attempts made to obtain optically active compounds of the type  $NQRT$  have all given negative results, but it is not safe to conclude from this fact that these compounds have a planar configuration; it is possible that instead they have a dissymmetric pyramidal configuration but are racemized easily by passage through an intermediate planar configuration, thus

That this second explanation of the optical inactivity of amines of the form  $NQRT$  is the correct one has been shown by studies of spectra, of dipole moments, of crystal structure, and of electron diffraction.

In compounds of trivalent nitrogen of the type  $-X=N-Y$ , where the nitrogen atom is directly linked to only two other atoms, and, therefore, to one of them by a double bond, the stereochemistry of the nitrogen atom was established at an early date by the classical stereochemical methods (*i.e.*, by consideration of isomer numbers and not with the use of the physical methods employed with the amines). Thus, oximes can generally be prepared in two isomeric modifications if the two substituents attached to the carbon atom doubly bonded to the nitrogen are dissimilar. The two isomeric forms are represented by the con-

figurations IV and V.

In these configurations the carbon, nitrogen and oxygen atoms, and the atoms of the groups R and T joined directly to the central carbon atom are considered to lie in the same plane. The situation is thus closely analogous to that in the ethylenic compounds considered previously, like maleic and fumaric acids; the only significant difference is that the nitrogen atom here forms three bonds whereas the corresponding carbon atom in the ethylenic compounds forms four. (Sometimes, the unshared pair of electrons on the nitrogen atom represented by the pair of dots, is said to act as a fourth valence bond.)

The above interpretation of the isomerism of the oximes, due to A. Hantzsch and A. Werner (1890), is confirmed by the optical activity of the cyclic oxime VI, demonstrated by W. H. Mills and A. M. Bain (1910).

Further examples of stereoisomeric nitrogen compounds, which owe their isomerism to restricted rotation about a double bond to the nitrogen atom, include the N-methyl oximes VII and VIII, the azo compounds IX and X and the azoxy compounds XI and XII. The so-called stable and labile diazo-hydrates (*see DIAZO COMPOUNDS*) were also considered by Hantzsch to be stereoisomers

of each other with the configurations XIII and XIV, respectively; this view, although probably correct, has been contested by other authors.

## VI. THE STEREOCHEMISTRY OF THE REMAINING ELEMENTS

For reasons of convenience, the various remaining elements are classified below on the basis of their co-ordination numbers. In general, a given element in a given compound is said to have a co-ordination number N, or to be N-co-ordinated, if in the molecules of that compound each atom of the element in question is joined to N distinct other atoms by bonds that are not broken ionically in solution. For example, in sulfuric acid,  $H_2SO_4$ , the co-ordination number of sulfur is four, since each sulfur atom is joined to four oxygen atoms by bonds of the type stated; similarly, the co-ordination number of oxygen in the same substance is one, since the oxygen-hydrogen bonds are broken ionically in solution and so do not contribute to the co-ordination number. In those instances in which the nonionizable union between each atom and each of its neighbours consists of a co-valent single bond, the co-ordination number of each atom is equal to its valence.

**1. Elements of Co-ordination Number 3.**—Sulfonium salts  $[SQRT]^+X^-$ , in which three dissimilar hydrocarbon radicals are linked to the sulfur atom, were shown to be dissymmetric by W. J. Pope and S. J. Peachey, and S. Smiles (1900); the sulfonium ion,

therefore, has a nonplanar configuration as in XV. Other analogous compounds of sulfur are the sulfinic esters XVI, the sulfoxides

XV

XVI

XVII

XVIII

XVII and the sulfilimines XVIII; each of these has been shown to have a similar nonplanar configuration, since optically active representatives of the three classes have been obtained, principally by H. Phillips and J. Kenyon (1925-27).

Optically active selenonium salts (analogous to the above sulfonium salts) were obtained by W. J. Pope and A. Neville (1902), and optically active telluronium salts were obtained by T. M. Lowry and F. L. Gilbert (1929). Consequently, the 3-co-ordinated selenium and tellurium atoms must be nonplanar.

That trivalent arsenic is able to maintain a pyramidal configuration has been shown by the resolution of an arsine, AsRQT, with three dissimilar substituents. In this respect, arsenic resembles sulfur, selenium and tellurium rather than nitrogen. Optically inactive stereoisomers of presumably the cis-trans type have been obtained when two trivalent arsenic atoms are present in a ring.

**2. Elements of Co-ordination Number 4.**—In the first short period (*see* PERIODIC LAW), besides both carbon and nitrogen, the elements beryllium and boron can have co-ordination number four, and there is evidence that the atoms of each of these elements then have the four radicals tetrahedrally disposed about them. This was demonstrated for beryllium by the production of an optically active compound of the type XIX (W. H. Mills and R. A. Gotts, 1926), and for boron in a similar way by J. Böseken and J. Meulenhoff (1924).

The molecular dissymmetry of silicon compounds of the type SiQRTZ has been established by F. S. Kipping, and the investigation of the configuration of 4-co-ordinated zinc by the method used for 4-co-ordinated beryllium has shown that its valencies are also tetrahedrally distributed. Phosphorus and arsenic, like nitrogen, have also been shown to have the tetrahedral configuration when 4-co-ordinated—phosphorus through the optical activity

XIX

XX

XXI

of a phosphine oxide XX (J. Meisenheimer and L. Lichtenstadt, 1911), and arsenic through that of an arsine sulfide XXI. Optically active arsine oxides RQTAs<sup>+</sup>—O<sup>−</sup> and arsonium salts [RQTZAs]<sup>+</sup>X<sup>−</sup> are also known. The existence of diastereomers and of meso forms has been demonstrated with compounds containing two such asymmetric phosphorus or arsenic atoms.

It is not universally true, however, that when an atom is linked directly to four other atoms these must be arranged around it tetrahedrally. Thus, many compounds of 4-co-ordinated platinum containing a complex of the type PtA<sub>2</sub>B<sub>2</sub> occur in two inactive, but evidently stereoisomeric, modifications; typical examples include the doubly charged cation [Pt(NH<sub>3</sub>)<sub>2</sub>(C<sub>6</sub>H<sub>5</sub>N)<sub>2</sub>]<sup>2+</sup> and

XXII

XXIII

the neutral molecule Pt(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>. This isomerism is clearly incompatible with a tetrahedral arrangement of the radicals about the platinum atom and is to be explained most simply by the supposition that 4-co-ordinated platinum has a plane configuration. The isomers are of the types XXII (cis) and XXIII (trans).

**3. Elements of Co-ordination Number 6.**—Werner's proof that substances like the compounds of metallic salts with ammonia (formerly regarded as "molecular compounds") are co-ordination compounds in which a certain number of atoms or groups, most frequently six, are directly attached to the metallic atom (CoCl<sub>3</sub>·6NH<sub>3</sub>, for example, having the structure XXIV)

XXIV

brought with it the problem of determining how these six groups are disposed about the central atom. If it is assumed that the valencies by which they are attached are equivalent (and this is supported by the absence of isomerism which should otherwise occur), three arrangements are possible: the plane hexagonal XXV, the prismatic XXVI and the octahedral XXVII. (For

XXV

XXVI

XXVII

ease of visualization, the respective geometrical figures are outlined, the central atom is represented by a large dot and the valence bonds are not shown. A substituent is supposed to occupy each of the positions marked by a corner of the figure.)

A decision among these three possible configurations was obtained by investigating the compounds formed by linking the co-ordination positions together in pairs through four-membered chains, as can be done, for example, by the threefold replacement of two molecules of ammonia, NH<sub>3</sub>, by one of ethylenediamine, H<sub>2</sub>N—CH<sub>2</sub>—CH<sub>2</sub>—NH<sub>2</sub> (or of two nitrito groups, NO<sub>2</sub>, by an oxalato group —O<sub>2</sub>C—CO<sub>2</sub>, or the like) so as to produce a complex in which the metallic atom forms a common member of three symmetrical five-membered rings, as in XXVIII. Since it seems

XXVIII

most probable that only adjacent co-ordination positions can be bridged in this way, the possible configurations for the tricyclic ion are those indicated by the dotted lines in the four different

XXIX

XXX

XXXI

XXXII

diagrams XXIX-XXXII. Of these, the first three are evidently symmetrical, but the last is dissymmetrical, for it possesses only twofold and threefold axes of rotation. Experimental investigation of the salts of these tricyclic ions has shown that they can be produced in optically active forms. The ions are thus dissymmetric and must consequently have the last configuration XXXII. It is, therefore, to be concluded that in such compounds the six valencies of the central metallic atom are octahedrally disposed.

This conclusion is confirmed by the occurrence of a different type of stereoisomerism shown by complexes of the type  $MA_2B_4$ , such as are contained in the diacidotetrammine salts of cobalt and chromium. These compounds should exist in three isomeric forms if their configuration is hexagonal and in four if it is prismatic, but in only two if it is octahedral; the alternative arrangements are then those in which the two groups A lie at the ends

XXXIII

XXXIV

(1) of an edge as in XXXIII (cis compound), and (2) of a diagonal as in XXXIV (trans compound) of the octahedron. The number of isomers actually found is two. Moreover, in dicyclic derivatives of this type like  $[en_2CoCl_2]^+ Cl^-$ , where *en* represents ethylenediamine, the isomer with the cis configuration can be obtained optically active, whereas the other, the trans isomer, cannot be resolved. These facts are in accordance with the con-

XXXV

XXXVI

figuration XXXV for the cation of the cis isomer, and XXXVI for the cation of the trans isomer.

**STEREOTYPING**, in printing, is the process of making a duplicate metal or plastic printing plate cast from a mold or matrix of composed type.

In 1725, William Ged (*q.v.*) of Edinburgh developed a metal plate with which he could print on a standard letterpress. By impressing a page of set type into moist gypsum, Ged produced a matrix from which he could cast his plate of type metal. His efforts to publish books by stereotype failed and after his death his invention was almost forgotten. It was reintroduced in 1804 by Charles Stanhope, 3rd earl of Stanhope, who used plaster of paris for his molds.

Stereotyping was not markedly successful until after the introduction of the papier-mâché matrix by Claude Genoux, a French printer, in 1829. In the Genoux process, layers of wet blotting and tissue paper, called flong, were placed on the composed type and the wet paper was forced down around the type by beating with a broad, stiff brush.

New and improved equipment was developed as a result of the adoption of the paper matrix. Paper molds of set type were prepared by revolving rollers or by direct-pressure machines. The curved casting box was developed in 1854 and, with the production of the curved plate, printing by rotary presses became practicable. The dry-mat process, which substituted dry mats for wet ones and is the process employed in most modern stereotyping, appeared in the last decade of the 19th century. Modern mat-making, casting and printing equipment is automatic. Plastic materials have been utilized in the preparation of printing plates; these plates offer lightness, strength, a smooth surface and faithful reproduction.

**STERILITY**: see FERTILITY AND FECUNDITY; REPRODUCTION; REPRODUCTIVE SYSTEM: *Diseases and Their Medical Treatment*: Sterility; Spermatocord.

**STERLING AREA**, a group of states that keep their currencies aligned with British sterling. Following the devaluation of sterling in September 1931 the British and other countries that continued to maintain parity with sterling and to hold their exchange assets in London had become known as the sterling bloc. When World War II brought exchange control and prospective exchange shortage, particularly of dollars, those countries with the closest ties to London adopted parallel policies of monetary collaboration.

There was no formal constitution of the sterling area and no centralized administration or elaborate machinery. Members in the mid-1960s were, besides the United Kingdom and the dependent colonies and protectorates, Australia, New Zealand, India, Pakistan, Ceylon, Burma, Libya, Iraq, Jordan, Ireland and Iceland. South Africa was a member insofar as it contracted to sell part of its gold production to the Bank of England. Egypt and Sudan were members until 1947, Palestine until 1948, Rhodesia until 1965, Belgian Congo and Ruanda-Urundi 1941-44, Syria and Lebanon 1941-44, and the Faeroe Islands 1941-48. Some of the colonies that were dependent in 1939—Gold Coast, Nigeria, Malaya, Northern Rhodesia, the West Indies—subsequently became self-governing; all remained members but, since they were large dollar-earners, it was anticipated that their independence would test the viability of the sterling area.

Within the sterling area there was relative freedom of transferability, though at times restrictions were imposed, particularly in respect to blocked sterling balances. Members kept their currencies aligned with sterling, but not necessarily at full prewar parity. The overseas members kept their exchange assets in London. Generally the independent members drew from the dollar pool as much as they put into it.

The dependent members, including until the late 1950s Ghana, Nigeria, and the Federation of Malaya, earned dollars and drew (or accumulated) sterling. Their continued membership rested upon access to the British capital market as well as upon traditional currency and trading ties.

Except for the dependent colonies, the administration of exchange control and the use of dollars rested in the hands of the central banks, who followed parallel policies and maintained close consultative cooperation with the Bank of England and with each other. In 1947 the Sterling Area Statistical Committee was formed to facilitate the exchange of information.

Periodic meetings of the Commonwealth finance ministers maintained liaison among governments, but actual administration was decentralized and dependent upon cooperative understanding, particularly among the central banks. With the growing independence of some members of the sterling area has come a tendency for each country to build up and hold its own currency reserves instead of centralizing them in London.

(J. B. CE.)

**STERLITAMAK**, a town of the Bashkir Autonomous Soviet Socialist Republic in the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the left bank of the Belaya River, at

its confluence with the Sterlya, about 75 mi. S of Ufa. Pop. (1959) 111,575. Founded in the 18th century, it only acquired importance with the industrialization of the Urals after the Revolution and especially with the development of the Second Baku oil field after World War II. It is a crossing point of railways southward from Ufa and westward from Magnitogorsk. Oil refining is important and other industries include machine building, production of synthetic rubber, soda (using local salt) and cement, flour milling, distilling, and leather working. (R. A. F.)

**STERN, OTTO** (1888– ), German-U.S. theoretical physicist and Nobel Prize winner, was born in Sorau (now Zary, Pol.), on Feb. 17, 1888. He received the degree of doctor of philosophy in physical chemistry from the University of Breslau in 1912. Interested in the research work of Albert Einstein, he joined Einstein at the University of Prague and followed him to the University of Zürich, where he received the *venia legendi* for physical chemistry. Early in 1914 Stern joined the faculty of the University of Frankfurt, where he remained until 1921 except for a period of military service during World War I.

After a short term as associate professor of theoretical physics at the University of Rostock, he was appointed to the chair of physical chemistry at the University of Hamburg in 1923. Resigning this position in 1933 he accepted shortly thereafter an invitation to join the Carnegie Institute of Technology in Pittsburgh, Pa., as research professor of physics. In 1945 he retired as emeritus professor to Berkeley, Calif.

Stern's earlier scientific contributions belong to the field of theoretical physics, the most important ones dealing with statistical thermodynamics. After 1919, however, his research was more experimental and was mostly devoted to the development and application of the molecular-beam method, a very powerful tool for the investigation of the properties of atoms, molecules, and atomic nuclei. A series of brilliant experiments designed to answer crucial questions of physical theory won him international recognition (see ATOMIC AND MOLECULAR BEAMS).

Stern was awarded the Nobel Prize for Physics in 1943 for the first measurement of the magnetic moment of the proton.

See T. N. Levitan, *Laureates: Jewish Winners of the Nobel Prize* (1960). (I. EN.)

**STERNBERG, LEV YAKOVLEVICH** (1861–1927), Russian ethnographer, noted for his work on the Gilyak (Nivkh) people of Sakhalin Island and the neighbouring parts of the Siberian mainland.

Born in Zhitomir in the Ukraine on May 3 (new style; April 21, old style), 1861, he studied at the University of St. Petersburg and later in the law faculty in Odessa. He was twice arrested for revolutionary activities and exiled to the island of Sakhalin for participation in the Narodnaya Volya (People's Will) Party. While in exile he began his studies of the Gilyak and Oroch. After return from exile he remained under police surveillance in Zhitomir until in 1899 he was able to return to St. Petersburg to pursue his ethnographic studies (see GILYAK).

From 1902 through 1917 he continued his work, at the same time being active in Russian and Jewish social movements. He traveled to museums in Berlin, Leipzig and elsewhere, and he also studied the Ainu and the Tungus peoples. After the Revolution of 1917 he organized the teaching of ethnography at the University of Leningrad with V. G. Bogoraz. Sternberg died at Dudergof, near Leningrad, Aug. 14, 1927. (L. K.)

**STERNE, LAURENCE** (1713–1768), English novelist, the author of *Tristram Shandy*, was born at Clonmel, Tipperary, on Nov. 24, 1713. His father, Roger Sterne, was a poor and improvident soldier who belonged to a gifted and hardheaded family which had produced an archbishop of York, a great-grandfather of the novelist. Sterne disliked his mother, who was of partly French descent; but he idolized his father, and his early memories of him, and of the scenes of military life that he saw as he moved about with his mother after his father's regiment, were to serve him as inspiration later in life. In 1723 or 1724 he was sent to a school near Halifax, Yorkshire, and in 1733 he entered Jesus college, Cambridge, as a sizar. At Cambridge, where he is said to have "read a little, laugh'd a great deal" and amused himself by

PORTRAIT BY AN UNKNOWN ARTIST; PHOTO, THE BETTMANN ARCHIVE

STERNE

"puzzling his tutors," he became friendly with John Hall (later Hall-Stevenson), a wealthy young wit of dissipated habits whose home at Skelton castle (renamed "Crazy castle") he was often to visit. He delighted in exploring the extensive library there, which was rich in what booksellers term "curiosa." From an early age Sterne had been an inquisitive reader: from his own writings it is clear that he knew such writers as Rabelais, Cervantes, Burton, Montaigne, Erasmus, Horace and Swift. He was also a great admirer of "the sagacious Locke," whose theory of the "association of ideas" lies behind *Tristram Shandy*.

Quite early in life Sterne realized that he was tubercular, and this discovery increased his propensity to snatch at life and its pleasures while there was still

time. It was no sense of vocation that led him to make his career in the church, but rather the influence of his uncle Jacques, a pluralist who was both archdeacon of Cleveland and precentor of York.

Having taken his degree in 1737 Sterne entered the church the following year. Although his vicarage was at Sutton-on-the-Forest near York he preferred to live in York, then a centre of fashionable life and church politics. In 1741 he married a wealthy young woman, Elisabeth Lumley. She was a difficult woman, irritable and self-righteous, while Sterne was a capricious and unfaithful husband, so that the marriage was not a success. In the year of his marriage Sterne became a prebendary of York. He frequently preached in York cathedral, with considerable success: although he had a weak voice he studied the art of preaching, and it is partly to this that the interest in posture and gesture that is so evident in *Tristram Shandy* must be attributed.

But for an ecclesiastical controversy his famous book might never have been written. Sterne began as a controversialist in support of his uncle. Then the two men fell out, and Jacques Sterne managed to do his nephew permanent harm by spreading a story that the novelist's mother and sister were lodging in a debtor's prison because he was too mean to support them. For a while Sterne withdrew from ecclesiastical politics, but in 1758 he returned and wrote *A Political Romance*, published early in 1759 and later renamed *The History of a Good Warm Watch-Coat*. This satire on a Dr. Topham who had drawn into his own hands most of the legal offices connected with the diocese of York is a precursor of *Tristram Shandy*, and it must have been while he was writing it that he realized his genius for comedy and satire. At the beginning of 1759 he wrote the opening volumes of *Tristram Shandy*, which were published on Jan. 1, 1760.

Like *Hudibras* and *Don Juan* (two satires with which it has something in common), *Tristram Shandy* came out in parts (nine in all) and was never completed. The full title—*The Life and Opinions of Tristram Shandy, Gentleman*—gives one a hint of the nature of the book: this is not (like so many novels of the time) *The Life and Adventures of somebody*: it deals with opinions, not with things. The reason for this is given in the motto of the first two volumes: "It is not things, but opinions about things, that throw mankind into confusion." Talk rather than action constitutes the "plot" of the book. Thus *Tristram Shandy* could not possibly have been the first novel: it is (among other things) a sort of satire on its own precursors: it cocks a snook at the rigorous morality of Samuel Richardson, the careful plot-construction of Henry Fielding and the violent adventures of Tobias Smollett. Its own morality may best be described as "relaxed": it has (in the usual sense) no plot whatever: while its characters

so far from being involved in exciting adventures, seldom even venture out-of-doors. The book opens with an account of the begetting (not the birth) of its hero, so providing Sterne with a splendid occasion for a discussion of heredity, education and life in general. It takes the hero a long time to get born, but the time is most agreeably filled in by an account of the conversations of his father and Uncle Toby *de omnibus rebus et quibusdam aliis*. The most important structural device is that of the association of ideas: instead of limiting himself to one subject, as most writers do, Sterne allows his mind to wander freely from one topic to another, as happens in a state of reverie. The result is that his book, while it lacks all logic of the usual sort, has yet a subliminal logic of its own which gives it a remarkable hold on the minds of its readers.

On the publication of the first part of *Tristram Shandy* Sterne found himself famous, though many readers were shocked when they discovered that it was the work of a cleric. He moved to a new house near Stillington and went on with his book. He delighted in his celebrity, dining out constantly on his visits to London; but his health declined, and in 1762 he set out on an extended trip in France and Italy in search of the sun and a renewal of health. In France he found himself as famous as in his native country.

The main events during the remainder of his life were the publication of further installments of *Tristram Shandy* and his infatuation with Elizabeth Draper, a deeper and more sentimental love affair than most in his life. *The Journal to Eliza*, which he wrote for her, reveals the pathological state of the emotions which inspired *A Sentimental Journey Through France and Italy* (1768), a travel book of a new kind in which Sterne concentrates on the effect of his travels on himself, dealing particularly with such "sentimental" experiences as the flirtations in which he became involved as he traveled about the continent. As a sort of riposte to Smollett's *Travels Through France and Italy*, Sterne concentrates on whatever had called forth his affections. The result is a work much slighter than *Tristram Shandy* which yet had a great influence on European literature and helped to give the word "sentimental" its international currency. He died in London on March 18, 1768.

**BIBLIOGRAPHY.**—The first good edition of his *Works* (including his *Sermons and Letters*) appeared in 10 volumes in 1780. There is a 12-vol. edition by Wilbur L. Cross (1904). The only authentic text of *Tristram Shandy*, however, is that edited by J. A. Work (1940). The *Letters* were edited by L. P. Curtis (1934). J. Ferriar's *Illustrations of Sterne* (1798; rev. ed. 1812) is an interesting early study. Much the best biographical and critical studies are *The Life and Times of Laurence Sterne*, by W. L. Cross (1909; rev. ed., 1929) and *Laurence Sterne, de l'homme à l'oeuvre*, by H. Fluchère (1961). (I. J.)

**STEROIDS** in chemistry, biology, and medicine make up a large group of naturally occurring substances and their synthetic derivatives. All possess as a fundamental structure the four-membered hydrocarbon ring system known as perhydrocyclopentamethene (I), for convenience represented by the diagram (II).

The steroids are colourless crystalline solids that differ among themselves in the nature of substituent groups attached to this basic nucleus. Steroid compounds are intimately concerned with a variety of life processes and may be divided into seven principal classes: sterols, bile acids, sex hormones, adrenal cortical hormones, insect hormones, cardiotonic agents, and sapogenins as discussed below.

Because of the large variety of known steroid compounds, the problem of naming them is formidable. Two systems of steroid nomenclature are employed. So-called trivial nomenclature is

based on the arbitrary names given to important natural steroids upon their discovery; compounds closely related in structure to these substances are named as derivatives thereof. Somewhat analogous to trivial names are the nonproprietary or generic names approved for new therapeutic steroid drugs by the United States Adopted Names (USAN) Council in cooperation with the World Health Organization. In systematic nomenclature compounds are designated as derivatives of certain reference hydrocarbons, and the systematic name denotes unambiguously the complete structure of the compound. Both types of names are employed in the following section; an explanation of steroid nomenclature is given in the section *Steroid Nomenclature* below.

## CLASSES OF STEROIDS

**Sterols.**—The sterols are constituents of the lipid material of the cells of practically all living organisms. In all these compounds the steroid nucleus is substituted with a  $\beta$ -hydroxyl group at position 3 and with a branched side chain containing eight, nine, or ten carbon atoms (see *Steroid Nomenclature*). The predominant sterol of the higher animals is cholesterol, whereas lower

animals and plants possess a variety of other sterols, most of them with the longer side chains. Some of the more than 30 different sterols that have been isolated from various species are listed as Table I.

TABLE I.—Representative Sterols

Trivial name	Systematic name	Source
Cholesterol . . . .	cholest-5-en-3 $\beta$ -ol	animal cells
Cholestanol . . . .	5 $\alpha$ -cholestan-3 $\beta$ -ol	animal cells
(dihydrocholesterol)		
Coprostanol . . . .	5 $\beta$ -cholestan-3 $\beta$ -ol	feces
Lathosterol . . . .	5 $\alpha$ -cholest-7-en-3 $\beta$ -ol	with cholesterol
7-Dehydrocholesterol . . . .	cholesta-5,7-dien-3 $\beta$ -ol	with cholesterol
(provitamin D <sub>2</sub> )		
Ergosterol . . . .	ergosta-5,7,22-trien-3 $\beta$ -ol	yeast, ergot
(provitamin D <sub>2</sub> )		
Stigmasterol . . . .	stigmasta-5,22-dien-3 $\beta$ -ol	soybean
Lanosterol . . . .	4,4,14-trimethyl-5 $\alpha$ -cholesta-8,24-dien-3 $\beta$ -ol	wool fat, yeast, liver
Desmosterol . . . .	cholesta-5,24-dien-3 $\beta$ -ol	chick embryo, rat skin, liver
(24-dehydrocholesterol)		

Cholesterol (*q.v.*) is particularly abundant in hair, neural tissue, adrenal glands, and egg yolk, occurring both in the free form and esterified with various fatty acids. Cholesterol is obtained commercially by extraction from the brains and spinal cords of cattle. In animals cholesterol is synthesized in the liver (and probably in other tissues as well) from acetic acid, which, by way of acetoacetic and mevalonic acids, is converted to five-carbon isoprenoid units. Six of these units combine to form the linear molecule squalene, which, by appropriate folding and ring closure, leads to lanosterol, desmosterol, and finally to cholesterol. Cholesterol is metabolized to cholestanol and coprostanol, which are excreted. One established biochemical function of cholesterol is to serve as a precursor for the biosynthesis of steroid hormones in the gonads and adrenal glands and of bile acids in the liver; other physiological functions of cholesterol remain obscure. In contrast to the cholesterol of most tissues, which is in continual metabolic turnover, the cholesterol of the brain and other neural tissue is metabolically inert.

In the pathological condition of atherosclerosis, the deposition of cholesterol occurs within the lining of the aorta and arteries, a situation that often leads to coronary thrombosis and death. The amount and nature of fat in the diet markedly influences this phenomenon, as do the steroid sex hormones, since this disease is much less common in premenopausal women than it is in men and in postmenopausal women (*see* ARTERIES, DISEASES OF).

Certain sterols that possess double bonds in both the 5 and 7 positions have an important relationship to vitamin D, a factor that is necessary for the proper deposition of calcium in the growing bone; absence of vitamin D leads to the pathological condition of rickets. On irradiation with ultraviolet light, ergosterol is converted to calciferol or vitamin D<sub>2</sub>; 7-dehydrocholesterol similarly yields vitamin D<sub>3</sub>, which differs from calciferol only in possessing the cholesterol (C<sub>27</sub>H<sub>46</sub>) rather than the ergosterol (C<sub>28</sub>H<sub>44</sub>) side chain. Both substances are of about equal anti-

rachitic potency in humans, but vitamin D<sub>3</sub> is especially potent in chicks. The preparation of ergosterol from yeast and the synthesis of 7-dehydrocholesterol from cholesterol for transformation to the D-vitamins are important commercial processes. The anti-rachitic effects obtained by exposure of an individual to sunlight result from the photochemical conversion to vitamin D<sub>3</sub> of the small amounts of 7-dehydrocholesterol that accompany cholesterol in the skin. Similarly, the irradiation of milk endows it with vitamin D<sub>3</sub> formed from the 7-dehydrocholesterol present.

**Bile Acids.**—The bile acids constitute a group of acidic steroids that are present in animal bile in the form of bile salts in which the bile acid is linked through a peptide bond to the amino acids glycine or taurine. The predominant bile acid in human or cattle

bile is cholic acid, which occurs chiefly as the glycocholate bile salt. The acids of human (and cattle) bile are listed as Table II; related bile acids have been isolated from other species.

TABLE II.—Human Bile Acids

Trivial name	Systematic name
Cholic acid	3 $\alpha$ ,7 $\alpha$ ,12 $\alpha$ -trihydroxy-5 $\beta$ -cholanolic acid
Deoxycholic acid	3 $\alpha$ ,12 $\alpha$ -dihydroxy-5 $\beta$ -cholanolic acid
Chenodeoxycholic acid	3 $\alpha$ ,7 $\alpha$ -dihydroxy-5 $\beta$ -cholanolic acid
Lithocholic acid	3 $\alpha$ -hydroxy-5 $\beta$ -cholanolic acid

The bile acids and salts are synthesized in the liver from cholesterol and are discharged with the bile into the duodenum. The bile salts are surface-active agents that promote the absorption of fats through the intestinal wall. In conditions such as obstructive jaundice when sufficient amounts of bile do not reach the intestine, absorption of lipids is impaired (*see* DIGESTION).

The bile acids are obtained commercially from cattle bile. Deoxycholic acid is an important raw material for one industrial process for the production of cortisol and other related anti-

inflammatory steroids. Cholic acid, the most abundant bile acid, can be transformed into deoxycholic acid by chemical removal of the 7 $\alpha$ -hydroxyl group.

**Sex Hormones.**—The steroid sex hormones are produced primarily in the gonads (ovary in the female and testis in the male, under the stimulation of protein substances called gonadotrophins secreted by the pituitary. The sex hormones mediate the growth and development of the reproductive tract and accessory sex organs, and their maintenance and function.

Two types of hormones are produced at different stages of the ovarian cycle. The follicle containing the ripening ovum produces the estrogenic hormone estradiol (estra-1,3,5(10)-triene-3,17 $\beta$ -diol; British: oestradiol), which is primarily involved in the development of the female organs and the general feminine characteristics. After the mature ovum has been expelled into the fallopian tube, the wall of the ruptured ovarian follicle forms a yellowish body (corpus luteum) that secretes the progestational hormone progesterone (pregn-4-ene-3,20-dione). This substance exerts a marked stimulatory effect on the growth and secretion of the uterine lining. In combination with estrogen, it mediates the proper implantation of the fertilized ovum, the maintenance of pregnancy, and the preparation of the mammary gland for lactation. The high levels of estrogen and progesterone present during the latter stages of pregnancy are produced in the placenta.

The activity of an estrogenic hormone is evaluated by its effect in promoting growth of the uterus or in stimulating cellular changes in the vaginal epithelium of a castrated or immature rat or mouse. Progestational activity is determined by the extent of proliferation evoked in the uterine endometrium of a rabbit that has been previously stimulated with estrogen.

Insufficient progesterone production during pregnancy can result in abortion, and progestational hormones may be prescribed to prevent miscarriage. They are also used to alleviate headache and other pain accompanying menstruation. Progestational hormones seem to be of benefit in benign prostatic hypertrophy, a common disorder in men. Estrogenic hormones are employed for the relief of both psychic and physical (*e.g.*, osteoporosis) symptoms.

accompanying and following the menopause, for the suppression of lactation after pregnancy, and for the treatment of prostatic cancer and some types of breast cancer. Estrogenic hormones may help to prevent or ameliorate atherosclerosis. A combination of estrogenic and progestational hormones is used to treat ovarian hypofunction (amenorrhea), and to prevent ovulation by inhibiting the secretion of gonadotrophins by the pituitary.

Since neither estradiol nor progesterone is highly effective when given by mouth, synthetic derivatives are employed clinically for oral administration. The most widely used oral estrogens are 17 $\alpha$ -ethynylestradiol, its 3-methyl ether known as mestranol, and a simple nonsteroid, diethylstilbestrol, which shows all the major physiological actions of estradiol. Widespread interest in orally active estrogen-progestin combinations as antifertility or birth-control pills prompted the development of a number of oral progestational agents: these are either chemically modified progesterones or 17-ethynyl derivatives of 19-norandrogens (e.g., norethynodrel); that is, substances related to testosterone but lacking the angular methyl group at position 19. Typical oral progestins and progestin-estrogen combinations are listed in Table III.

TABLE III.—Oral Progestational and Antifertility Agents

Nonproprietary name (Trade name)	Systematic name	Antiovaratory product (with estrogen E or M*)
17-Hydroxyprogesterone caproate (Delalutin)	17-hydroxypregn-4-ene- 3, 20-dione, caproate	
Medroxyprogesterone acetate (Provera)	17-hydroxy-6 $\alpha$ -methylpregn- 4-ene-3, 20-dione, acetate	Provest (E)
Megestrol acetate	17-hydroxy-6-methylpregna- 4, 6-diene-3, 20-dione, acetate	Validan (E)
Chlormadinone acetate	6-chloro-17-hydroxypregna- 4, 6-diene-3, 20-dione, acetate	Lutal (M), C-Quens
Ethinisterone, 17-ethynyltes- tosterone	17-hydroxy-17 $\alpha$ -ethynyl- androst-4-en-3-one	
Norethindrone (Norlutin)	17-hydroxy-17 $\alpha$ -ethynylestr- 4-en-3-one	Norinyl, Ortho- Novum (M)
Norethindrone acetate (Norlutate)	17-hydroxy-17 $\alpha$ -ethynylestr- 4-en-3-one, acetate	Anovlar, Gestest, Norlestrin (E)
Norethynodrel	17-hydroxy-17 $\alpha$ -ethynylestr- 5(10)-en-3-one	Enovid (M)
Ethynodiol diacetate	17 $\alpha$ -ethynylestr-4-ene-3 $\beta$ , 17-diol, diacetate	Ovulen (M)
Lyndrenol	17 $\alpha$ -ethynylestr-4-en-17-ol	Lyndiol (M)
Dimethisterone (Secrosterone)	17-hydroxy-6 $\alpha$ -methyl-17 $\alpha$ - propynylestr-4-en-3-one	Ovin (E), Oracon

\*E=17-ethynylestradiol; M=mestranol.

The female sex hormones have certain important applications in livestock production. Estrogens are used to promote weight gain in sheep and cattle and to impart tenderness to the flesh of poultry. The compounds generally used are diethylstilbestrol and a closely related nonsteroidal estrogen, dienestrol diacetate, administered either as a feed additive or a subcutaneous implant. Progestins are finding increasing application for synchronization of estrus in sheep and cattle; by temporary retardation of ovarian function an entire herd can be brought into estrus when artificial insemination facilities are available.

The testis chiefly produces the androgenic hormone testosterone (17 $\beta$ -hydroxyandrost-4-en-3-one). Testosterone stimulates the development and function of the male sex organs, and such masculine characteristics as facial hair and deepening of the voice. In addition to promoting marked growth of specific sexual tissues, testosterone exhibits a general anabolic (tissue-building) effect. Androgenic activity is measured by the stimulation of growth either of the comb in chicks and capons or of the prostate gland

and seminal vesicles of immature or castrated rats.

Testosterone and similar androgenic hormones are used clinically for the treatment of testicular insufficiency (eunuchoidism), the suppression of lactation, the therapy of certain types of breast cancer, and the treatment of frigidity in women. Because of their general anabolic effect, androgenic hormones are employed to promote tissue building in debilitated conditions, or (in combination with growth hormone) for children whose growth is deficient. Testosterone is usually administered parenterally as an ester (e.g., propionate); for oral administration a 17-methyl or ethyl derivative is employed (Table IV). Chemical modifications of the ster-

TABLE IV.—Androgenic and Anabolic Agents

Nonproprietary name (Trade name)	Systematic name
Testosterone propionate (Perandren, Neo-Hombreol)	17 $\beta$ -hydroxyandrost-4-en-3-one, propionate
Testosterone enanthate (Delatestryl)	17 $\beta$ -hydroxyandrost-4-en-3-one, heptanoate
Nandrolone phenpropionate (Durabolin)	17 $\beta$ -hydroxyestr-4-en-3-one, phenylpropionate
Methyltestosterone (Metandren, Oreton-M)	17-hydroxy-17 $\alpha$ -methylandrost-4-en-3-one
Methandrostenedione (Dianabol)	17-hydroxy-17 $\alpha$ -methylandrost-1, 4-dien-3-one
Fluoxymesterone (Halotestin, Ultadren)	9-fluoro-11 $\beta$ -17-dihydroxy-17 $\alpha$ -methylandrost-4- en-3-one
Norethandrolone (Nilevar)	17-hydroxy-17 $\alpha$ -ethylestr-4-en-3-one
Oxymetholone (Adroyd, Anadrol)	2-hydroxymethylene-17-hydroxy-17 $\alpha$ -methyl-5 $\alpha$ - androst-3-one
Oxandrolone (Anavar)	17-hydroxy-17 $\alpha$ -methyl-2-oxa-5 $\alpha$ -androst-3-one
Stanozolol (Winstrol)	17-hydroxy-17 $\alpha$ -methyl-5 $\alpha$ -androstano-[3, 2-c]- pyrazole

oid structure have been effected (e.g., oxandrolone) in an attempt to minimize masculinizing effects while retaining anabolic action.

The biochemical precursor of the natural sex hormones is cholesterol. Estradiol is converted metabolically to estrone (3-hydroxyestra-1,3,5(10)-trien-17-one), an active estrogen, estriol (estra-1,3,5(10)-triene-3,16 $\alpha$ ,17 $\beta$ -triol), and 16-epiestriol (estra-1,3,5(10)-triene-3,16 $\beta$ ,17 $\beta$ -triol), all of which are excreted in the urine. During pregnancy, when large amounts of estrogens are being produced by the placenta, some of the estriol excreted may arise from a source other than estradiol. The high urinary level of estriol in the latter stages of pregnancy is an indication of placental function; a drop in the excretion of this steroid may be associated with death of the fetus unless prompt surgical delivery is effected. The principal urinary metabolite of progesterone is pregnanediol (5 $\beta$ -pregnane-3 $\alpha$ ,20 $\alpha$ -diol), which furnishes a measure of progesterone production in an individual. During pregnancy, urinary pregnanediol levels usually are checked periodically to determine the need for additional progesterone to prevent abortion. Testosterone is converted metabolically to androsterone (3 $\alpha$ -hydroxy-5 $\alpha$ -androst-17-one) and etiocholanolone (3 $\alpha$ -hydroxy-5 $\beta$ -androst-17-one), which are excreted in the urine; the latter substance is pyrogenic when administered to humans, and its production in abnormal amounts has been implicated in certain hitherto unexplained conditions of fever.

The steroid sex hormones are manufactured commercially from more abundant steroids, chiefly sapogenins; diethylstilbestrol is synthesized inexpensively from simple organic chemicals.

**Adrenal Cortical Hormones.**—When stimulated by a protein hormone from the pituitary called adrenocorticotropin (ACTH), the cortex or outer capsule of the adrenal gland converts cholesterol into a variety of steroid hormones. The major functions of these adrenal secretions are in regulating salt and water balance in the body by promoting the retention of sodium and excretion of potassium ions (mineralocorticoid activity) and in helping the individual cope with stress by promoting the rapid conversion of protein to carbohydrate (glucocorticoid activity). Unlike the sex hormones the adrenal secretions are necessary for life; no organism (including man) can survive adrenalectomy long unless adrenal hormones are administered.

The principal glucocorticoid secreted by the adrenal in the human, monkey, or dog is cortisol (hydrocortisone or compound F). In the rodent it is the corresponding 17-deoxy compound known as corticosterone or compound B. The principal mineralocorticoid is aldosterone. Other active steroids from adrenal tissue include

the 11-dehydro analogue of cortisol known as cortisone (compound E, 17,21-dihydroxypregn-4-ene-3,11,20-trione), which shows considerable glucocorticoid activity, and 11-deoxycorticosterone (DOC, 21-hydroxypregn-4-ene-3,20-dione, 21-hydroxyprogesterone), which exhibits a modest salt-retaining activity.

The glucocorticoid activity of an adrenal hormone is evaluated in the adrenalectomized rat by its action in accumulating glycogen in the liver, in involuting lymphatic tissue, in maintaining the ability of the leg muscle to do work, or helping the animal withstand cold. Mineralocorticoid activity is evaluated through its effect in keeping adrenalectomized animals alive or through sodium retention following salt administration.

The earliest clinical use of adrenal hormones was in Addison's disease, a typically fatal adrenal insufficiency. Crude extracts of beef adrenal glands were first used, since pure compounds were scarce. With the discovery (1949) that cortisone or cortisol could remarkably ameliorate rheumatoid arthritis and other inflammatory conditions, the resulting demand for adrenal steroids had profound effect on the pharmaceutical industry. An intensive effort toward large-scale synthesis of cortisone and cortisol involved the difficult task of introducing the 11-oxygenated substituent characteristic of the glucocorticoids. The original procedure starting with deoxycholic acid involves transfer of the hydroxyl group from C<sub>12</sub> to C<sub>11</sub> and is still utilized. Since the discovery that incubation with certain strains of mold or fungus can introduce a hydroxyl group directly into position 11, most processes for producing adrenal hormones involve fermentation of progesterone derivatives obtained from sapogenins or stigmasterol.

Since they inhibit immune response to foreign substances, glucocorticoids are used to treat allergies and (with radiation and other drugs) to combat rejection of transplanted organs such as kidneys. These steroids involute lymphatic tissue, offering temporary benefit in some forms of leukemia and other lymphomas.

Synthetic modifications of the cortisol structure have been found to yield markedly increased glucocorticoid and anti-inflammatory properties with reduced side effects. Such alterations include a

1,2 double bond, a 6 $\alpha$ -methyl group, a 6 $\alpha$ - or 9 $\alpha$ -fluorine substituent, and a 16-hydroxy or 16-methyl group (e.g., dexamethasone). Some of the clinically important corticoid drugs, which embody a combination of these molecular features, are listed as Table V. Some of these substances also are available as water-soluble 21-phosphate esters for intravenous injection.

Some chemically modified steroids inhibit the mineralocorticoid actions of aldosterone; thus spironolactone (trade name: Aldactone) is used to combat excessive salt and water retention in such disorders as congestive heart failure, nephrosis, cirrhosis, and some types of hypertension.

**Insect Hormones.**—In the 1960s it was found that ecdysone, the hormone that mediates insect metamorphosis of larva to pupa and pupa to moth, is a steroid. Isolated from the prothoracic glands of silkworm pupae, it is 2 $\beta$ ,3 $\beta$ ,14,22,25-pentahydroxy- $\Delta^5$ -cholest-7-en-6-one. Probably other steroid hormones will be discovered to play a role in invertebrate organisms.

**Cardiotonic Agents.**—Two types of steroid found in nature exert a unique effect on the performance of the heart muscle in higher animals. These are the cardiac glycosides (illustrated by digitoxin) found in plants and consisting of a steroid genin or aglycone combined in glycosidic linkage through its 3-hydroxyl group with one or more molecules of a sugar; and the toad poisons (illustrated by bufotoxin) found in the skin and parotid gland secretions of toads and consisting of a steroid genin conjugated through its 14-hydroxyl group with suberylarginine, an amino acid derivative.

The cardiac glycosides are found in the leaves, flowers, seeds, roots, and bark of a large variety of plants, including digitalis, *Strophanthus*, squill, oleander, and ouabain. Extracts of such plants have long been recognized as toxic and have been employed as arrow poisons (inée), rodenticides (red squill), drugs for medieval ordeal trials, and folk remedies (foxglove). When administered in sublethal doses, the cardiac glycosides slow the heart rate and markedly increase the force and extent of contractions. They are of great benefit for treating conditions in which the heart lacks power (congestive heart failure, dropsy) or in which the rhythm has been disturbed (e.g., auricular fibrillation). The toad poisons exert a similar effect, and dried and powdered toad skin have long been used medicinally in China and Japan. Practices

TABLE V.—Corticoid Anti-inflammatory Agents

Nonproprietary name	Modification of cortisol structure	Trade name
Betamethasone . . . .	1-dehydro-,9-fluoro-,16 $\beta$ -methyl-	Celestone
Dexamethasone . . . .	1-dehydro-,9-fluoro-,16 $\alpha$ -methyl-	Decadron, Deronil, Dexameth, Gammacorten, Hexadrol
Fluocinolone acetonide . . . .	1-dehydro-,6 $\alpha$ ,9-difluoro-,16 $\alpha$ -hydroxy-,16,17-acetonide	Synalar
Fludrocortisone acetate . . . .	9-fluoro-,21-acetate	F-Cortef acetate, Alfiorone acetate, Florinef acetate
Fluormetholone . . . .	1-dehydro-,6 $\alpha$ -methyl-,9-fluoro-,21-deoxy-	Oxylone
Fluprednisolone . . . .	1-dehydro-,6 $\alpha$ -fluoro-	Alphadrol
Flurandrenolone . . . .	6 $\alpha$ -fluoro-,16 $\alpha$ -hydroxy-,16,17-acetonide	Cordran
Methylprednisolone . . . .	1-dehydro-,6 $\alpha$ -methyl-	Medrol, Wyacort
Paramethasone acetate . . . .	1-dehydro-,6 $\alpha$ -fluoro-,16 $\alpha$ -methyl-,21-acetate	Haldrone
Prednisolone . . . .	1-dehydro-	Delta-Cortef, Hydeltra, Meticortelone, Paracortol, Sterane
Prednisone . . . .	1-dehydro-,11-dehydro-	Deltasone, Deltra, Meticorten, Paracort
Triamcinolone . . . .	1-dehydro-,9-fluoro-,16 $\alpha$ -hydroxy-	Aristocort, Kenacort
Triamcinolone acetonide . . . .	1-dehydro-,9-fluoro-,16 $\alpha$ -hydroxy-,16,17-acetonide	Aristocort acetonide, Aristoderm, Kenalog

methods remain to be developed for the synthesis of cardiac aglycones and glycosides; material for clinical use is obtained by isolation from plant sources. Crystalline glycosides, as well as crude powders and extracts of digitalis leaves, find therapeutic use.

Hydrolysis of the cardiac glycosides by acid or by enzyme preparations removes the sugar groups and yields the steroid agly-

TABLE VI.—Typical Cardiac Aglycones

Aglycone	Systematic name	From glycoside
Digitoxigenin	3 $\beta$ ,14-dihydroxy-5 $\beta$ -card-20(22)enolide	digitoxin, dig. lanide-A
Periplogenin	3 $\beta$ ,5,14-trihydroxy-5 $\beta$ -card-20(22)enolide	periplocin, periplocymarin
Sarmentogenin	3 $\beta$ ,11 $\alpha$ ,14-trihydroxy-5 $\beta$ -card-20(22)enolide	sarmentocymarin
Digoxigenin	3 $\beta$ ,12 $\beta$ ,14-trihydroxy-5 $\beta$ -card-20(22)enolide	digoxin, dig. lanide-C
Gitoxigenin	3 $\beta$ ,14,16 $\beta$ -trihydroxy-5 $\beta$ -card-20(22)enolide	gitoxin, dig. lanide-B
Strophanthidin	3 $\beta$ ,5,14-trihydroxy-19-oxo-5 $\beta$ -card-20(22)enolide	cymarin, k-strophanthoside
Ouabagenin	1 $\beta$ ,3 $\beta$ ,5,11 $\alpha$ ,14,19-hexahydroxy-5 $\beta$ -card-20(22)enolide	ouabain
Scillarenin	3 $\beta$ ,14-dihydroxybufa-4,20,22-trienolide	scillarenin-A
Scilliglaucosidin	3 $\beta$ ,14-dihydroxy-19-oxobufa-4,20,22-trienolide	scilliglaucoside

cones. The simple aglycones are much less active physiologically than the complete glycosides. Some of the commonest aglycones are listed as Table VI. Characteristic features of this group of steroids are the unsaturated cyclic lactone side chain containing either four or five carbon atoms, 3 $\beta$ - and 14 $\beta$ -hydroxyl groups and the 14 $\beta$  ring junction that is unique among natural steroids.

**Sapogenins.**—The sapogenins are the steroid portions of glycosidic compounds (saponins) found in the leaves, seed, and roots of a number of plants (*Dioscorea*, yucca, agave, sarsaparilla, digitalis); they are called saponins because they form a soapy lather when mixed with water. Treatment of saponins with acid yields the sapogenins, characterized by a 3 $\beta$ -hydroxyl group and an eight-carbon side chain with two atoms of oxygen arranged in a bicyclic "spiroketal" structure (e.g., diosgenin).

On treatment with hot acetic anhydride, sapogenins are converted to the acetate esters of the so-called pseudo ( $\psi$ ) sapogenins (e.g.,  $\psi$ -diosgenin), which can readily be cleaved at the 20,22 dou-

ble bond to form 20-ketopregnane derivatives convertible to progesterone. Because of their abundance and ease of side-chain

TABLE VII.—Typical Steroid Sapogenins

Trivial name	Systematic name
Diosgenin	25 $\alpha$ -spirost-5-en-3 $\beta$ -ol
Yamogenin	25 $\beta$ -spirost-5-en-3 $\beta$ -ol
Smilagenin	5 $\beta$ ,25 $\alpha$ -spirostan-3 $\beta$ -ol
Sarsasapogenin	5 $\beta$ ,25 $\beta$ -spirostan-3 $\beta$ -ol
Hecogenin	3 $\beta$ -hydroxy-5 $\alpha$ ,25 $\alpha$ -spirostan-12-one
Botogenin	3 $\beta$ -hydroxy-25 $\alpha$ -spirost-5-en-12-one
Gitogenin	5 $\alpha$ ,25 $\alpha$ -spirostane-2 $\alpha$ ,3 $\beta$ -diol
$\psi$ -diosgenin	furosta-5,20(22)-diene-3 $\beta$ ,27-diol
$\psi$ -sarsasapogenin	5 $\beta$ -furost-20(22)ene-3 $\beta$ ,27-diol

degradation, the sapogenins are the chief raw materials for the manufacture of steroid hormones. Diosgenin, the most important substance in this regard, is obtained from the roots of a species of *Dioscorea* that abounds in southern Mexico. The structures of typical sapogenins are given as Table VII.

## STEROID NOMENCLATURE

**Numbering.**—The four rings of the steroid nucleus are desig-

nated by letters and the individual carbon atoms by numbers (III). Naturally occurring steroids have an angular methyl group (18) attached at position 13, and most of them a similar methyl (19) at position 10; these are indicated in the formula by the short lines. Many steroids also have a side chain containing two, five, eight, nine, or ten carbon atoms attached to the nucleus at position 17 and numbered as shown.

**$\alpha$  and  $\beta$  Configuration.**—Since the four valence bonds of a carbon atom have a tetrahedral relationship, the single substituent (I) at each of the tertiary positions (ring junctions) of the steroid nucleus will project toward one side or the other of the approximate plane formed by the steroid ring system. At all other (secondary) positions, one of the two substituents will project toward one side of this plane and the other substituent toward the opposite side. When the steroid nucleus is represented in the conventional manner with the ring system lying in the plane of the paper, the configuration at C<sub>13</sub> in all the known natural steroids is such that the 18-methyl group projects upward. Substituents on the nucleus projecting in the same direction as the C<sub>18</sub> methyl group are said to have a  $\beta$  orientation and are denoted in the formula by attaching that group with a solid line (IV). Conversely, substituents projecting toward the opposite side of the molecule (downward) have an  $\alpha$  orientation denoted by a broken or dotted line. Orientation at position 20 is defined according to the Fischer convention as  $\beta$  if the substituent projects toward the left, when the longest chain attached to this position is swung to the rear; and  $\alpha$  if it projects toward the right. For the pregnanes, this is easily visualized in the usual representation (V) where a  $\beta$ -oriented substituent projects upward. For steroids with longer side chains, 20 $\beta$  configuration (Fischer convention) signifies that the C<sub>21</sub> methyl group projects toward the left when the C<sub>22</sub> chain projects toward the rear (VI); this means that the tertiary hydrogen atom at C<sub>20</sub> projects upward in the usual diagram (VII) as well as in the cyclic structures spirostan and furostan.

The Fischer convention is used in analogous fashion to denote configuration at other asymmetric positions in the side chain, such as C<sub>24</sub> in ergosterol and stigmaterol and C<sub>25</sub> in the sapogenins. There are two series of natural sapogenins differing in configuration at position 25; formerly these were called *a* or "iso" and *b* or

"neo," but now that their stereochemistry has been established they can be designated as  $\alpha$  (or  $\alpha_z$  for Fischer) and  $\beta$  (or  $\beta_z$ ), respectively.

**Nomenclature.**—In trivial steroid nomenclature, compounds closely related in structure to the commonly occurring steroids are named as derivatives thereof by an appropriate prefix accompanied by a designation of the position and orientation of the added, missing, or altered feature. In addition to the usual chemical notations for substituent groups replacing hydrogen atoms (e.g., methyl-, chloro-, hydroxy-, oxo-), the following prefixes are commonly used in trivial steroid nomenclature: dehydro- (lacking two hydrogen atoms from adjacent positions); dihydro- (possessing two additional hydrogen atoms in adjacent positions); anhydro- (lacking the elements of water from adjacent positions); deoxy- (hydroxyl group replaced by a hydrogen atom); epi- (differing in configuration at a secondary position); iso- (differing in configuration at a tertiary position); nor- (lacking one carbon atom); and homo- (possessing one additional carbon atom).

Systematic nomenclature, though often cumbersome, affords an unambiguous name for any steroid structure. Here compounds are designated as derivatives of reference hydrocarbons whose names imply the structure and stereochemistry of the complete carbon skeleton. Since certain classes of steroids possess characteristic oxygen-containing groupings in the side chain, it is convenient also to use certain reference structures that include such groups.

Except for cardanolide and bufanolide, which imply the 14 $\beta$  configuration characteristic of the cardiotonic agents, these parent compounds have the "backbone" configuration common to most natural steroids: 8 $\beta$ , 9 $\alpha$ , 10 $\beta$ , 13 $\beta$ , and 14 $\alpha$ , as well as 17 $\beta$  and 20 $\beta$  in steroids with side chains. Thus configuration at any of these positions is not specified in the name or indicated in the formula unless it differs from that of the foregoing. Since compounds with both 5 $\alpha$  or 5 $\beta$  configurations are found in nature, the configuration at position 5 must be indicated, giving rise to two series of steroids for each parent hydrocarbon; 5 $\alpha$ -androstan-5 $\beta$ -androstan-5 $\beta$ , and so on. Until 1956 systematic nomenclature employed the names androstane and cholestane only for 5 $\alpha$  compounds and used pregnane and cholane for 5 $\beta$  compounds. 5 $\beta$ -Androstane was known as etiocholane or testane, 5 $\beta$ -cholestane as coprostan-5 $\alpha$ -pregnane as allopregnane, and 5 $\alpha$ -cholane as al-choholane. Names based on this former system are still encountered.

The presence of unsaturation is indicated by changing the syllable "ane" to "ene" for one double bond, "adiene" for two double bonds, and so on, and inserting before this syllable the number of the lowest numbered carbon atom attached to the double bond. If the other carbon atom is not the next higher numbered, its number is also given enclosed in parentheses. If there is no other numerical prefix to the parent name, it is common in the American but not the British literature to place the numbers locating the unsaturation before the name (e.g., 4-androstene for androst-4-ene). Formerly, the symbol  $\Delta$  was placed before the number to

indicate unsaturation, but this practice, though still encountered, is unnecessary. Substituent groups with their position and orientation are indicated by the appropriate prefix or suffix. Although often disregarded in the older steroid literature, it is not proper to employ more than one suffix in a single name (e.g., 3 $\beta$ -hydroxy-5 $\alpha$ -

REFERENCE COMPOUNDS FOR SYSTEMATIC NOMENCLATURE (see TEXT)

androstan-17-one, not 5 $\alpha$ -androstan-3 $\beta$ -ol-17-one). The final "e" of the parent name is dropped when such a suffix begins with a vowel.

(E. V. Jr.)

**STESICHORUS** (c. 640–c. 555 B.C.), Greek lyric poet, born at Maturus in southern Italy, but active mainly at Himera in Sicily. His works, which are said to have extended to 26 books (about 15,000 lines), were mainly narrative lyric poems dealing with stories from mythology. Plato records that his severe treatment of Helen of Troy's conduct in one of them led to an attack of blindness, which was cured only after he had composed his *Palinodia*, or recantation (*Phaedrus*, 243 a–b). Stesichorus is credited also with originating bucolic poetry (*Daphnis*), and other forerunners of the romantic poetry of Hellenistic times are ascribed to him (*Calyce*, *Rhadine*). He wrote in the Doric dialect, and his poems were serious enough for Horace (*Odes*, iv.9.8) to speak of his *graves Camenae*, and for Quintilian (x.1.62) to describe him as “upholding on his lyre the burdens of epic poetry”; but information about his work is mostly secondhand, for hardly 100 lines of his writings survive. It is not even certain if he used the triadic stanza (consisting of strophe, antistrophe, and epode) which some authorities credit him with inventing.

For fragments see *Poetae melici Graeci*, ed. by D. L. Page, pp. 93–141 (1962). See also C. M. Bowra, *Greek Lyric Poetry*, 2nd ed., ch. 3 (J.N. A. D.) (1961).

**STETHOSCOPE**, a medical instrument used in listening to sounds produced within the body, chiefly in the heart or lungs (see AUSCULTATION). It was invented in 1816 and described in 1819 by R. T. H. Laënnec (q.v.), who used a perforated wooden cylinder to transmit sounds from the patient's chest (Greek *stethos*) to the physician's ear. This monaural stethoscope was modified to more convenient forms but has been largely supplanted by the binaural type, consisting of two flexible rubber tubes attaching the chest-piece to spring-connected metal tubes with earpieces. In listening to heart sounds, in particular, it is necessary to use both a bell-shaped, open-ended chest-piece, which transmits low-pitched sounds well, and the flat chest-piece covered with a semirigid disk (diaphragm type), which detects sounds of higher frequency. Instruments having both types of chest-piece, arranged so that they can be rapidly interchanged by turning a valve, are widely used, especially in the United States. (H. B. Sp.)

**STETTIN**: see SZCZECIN.

**STETTINIUS, EDWARD REILLY, JR.** (1900–1949), U.S. industrialist and statesman generally credited as one of the leading figures in the formation of the United Nations, was born Oct. 22, 1900, at Chicago, Ill. Stettinius attended the University of Virginia, Charlottesville, but did not take a degree. In 1924 he was employed by a subsidiary of General Motors Corporation and by 1931 had risen to an executive position in the corporation. He joined the United States Steel Corporation and in 1938, at the age of 37, became chairman of the board of directors of that firm. He was named chairman of Pres. Franklin D. Roosevelt's War Resources Board (1939), Lend-Lease administrator (1941–43), and undersecretary of state (1943). Stettinius served as U.S. secretary of state in 1944 but he resigned the following year to become the first U.S. delegate to the General Assembly of the United Nations. Earlier, he had been one of President Roosevelt's chief advisers at the Yalta Conference, and he played a principal role in the Dumbarton Oaks meetings that laid the groundwork for the United Nations. He died at Greenwich, Conn., Oct. 31, 1949. (H. J. Sc.)

**STEBEN, FREDERICK WILLIAM AUGUSTUS, BARON VON** (1730–1794), German soldier who helped train American troops during the Revolution, was born at Magdeburg, Prussia, Sept. 17, 1730, the son of an officer in the Royal Prussian Engineers. From about the age of 16 Steuben led a soldier's life and during the Seven Years' War (1756–63) rose to the rank of captain in the Prussian Army and for a time was attached to the general staff. After the close of the war he was retired from the army and became court chamberlain for the prince of Hohenzollern-Hechingen, was made a knight of the Order of Fidelity in the neighbouring margravate of Baden-Durlach in 1769, and at some unknown date apparently was created a baron (“Freiherr”). In 1777 rumors were afloat that he had been obliged to leave Hohenzollern-Hechingen for extremely unsavoury conduct, which may account for the failure of his attempts to secure a post with the

THE BETTMANN ARCHIVE

STEBEN: PORTRAIT BY RALPH EARL

British East India Company, or in the service of France, Austria, or Baden. Finally, he obtained a letter from Benjamin Franklin and Silas Deane, agents of the United States in France, introducing him to Gen. George Washington as a “Lieut. Genl. in the King of Prussia's Service,” fired with “Zeal for our Cause.” Armed with this letter, he arrived in America in December 1777.

Impressed by his fictitiously high rank, his pleasing personality, and Washington's favourable comments, Congress, in May 1778, appointed Steuben inspector general of the army with the rank of major general. He trained the soldiers admirably, adapting Prussian military ideas to the needs of his pupils; but he made such a nuisance of himself by threatening to resign unless he was given command of a division of troops that by July 1778 Wash-

ington wished he had never appeared. When Washington called his bluff by refusing to yield, Steuben stayed on and continued to render valuable service throughout the war, including the drafting of *Regulations for the Order and Discipline of the Troops of the United States* (1779), which served as the official manual until 1812. In 1780 his wish for command was granted; he served as a division commander in Virginia and participated in the siege of Yorktown.

After the war Steuben lived for some years so extravagantly in and near New York City that, despite large grants of money from Congress and the grant of 16,000 ac. of land by the state of New York, he fell into debt. Finally, after ceaseless importunity and gross misstatements as to revenues in Germany lost to him in coming to America, Congress voted him in 1790 a life pension of \$2,500 per year, which sufficed to maintain him on a farm he had cleared on his New York land grant, near present Remsen, N.Y. There, a bachelor to the end, he died Nov. 28, 1794.

See John McAuley Palmer, *General von Steuben* (1937), inadequate but valuable; Douglas S. Freeman, *George Washington*, vol. 5 (1952). (B. Kn.)

**STEBENVILLE**, a city of eastern Ohio, U.S., and the seat of Jefferson County, is on the Ohio River, 26 mi. N of Wheeling, W.Va. It is one of the state's oldest cities. The site was settled temporarily as early as 1765 by Jacob Walker and was occupied again with the building in 1786 of Ft. Steuben, named for Baron von Steuben, soldier and patriot of the American Revolution. The fort was abandoned with the outbreak of the Indian Wars in 1790. In 1797 a permanent settlement was laid out by two Pennsylvania land speculators, Bezaleel Wells and James Ross, who named it Steubenville. It was incorporated in 1805.

Adjacent to one of the nation's principal waterways in an area rich in coal and clay, the city early became an important manufacturing and commercial centre. The textile industry was its most important in the period after the War of 1812. Steubenville's economy centres upon the production of steel, chemicals, dinnerware, brick and tile, heaters, stoves, electrical equipment, paperboard, and ferroalloy metals. In the 1960 census Steubenville, with a population of 32,495, was named a central city of the Steubenville-Weirton standard metropolitan statistical area, comprising Jefferson County in Ohio and Brooke and Hancock counties in West Virginia, with a population of 167,756. For comparative population figures see table in OHIO: *Population*. See also WEIRTON. (P. R. S.)

**STEVENAGE**, a market town, urban district, and New Town of Hertfordshire, Eng., lies on the Great North Road 32 mi. (51 km.) N of Charing Cross, London, by road. Pop. (1961) 42,968.

The six hills along the Great North Road at the edge of the town are Romano-British burial mounds. The manor belonged to the abbot of Westminster at the time of the Domesday survey, and in 1281 the abbot obtained for the town a grant of a weekly market (now held twice weekly) and an annual fair, held in September. Stevenage was the first of the New Towns (*q.v.*) under the New Towns Act, 1946, and its population was scheduled at 80,000. In the New Town are an all-pedestrian-way shopping centre and interesting buildings such as St. George's Church, the girls' grammar school, and the County College. The old town contains St. Nicholas' parish church dating from the 12th century, old coaching inns, and a 16th-century grammar school. The predominant industry is electronics, but a variety of others includes engineering and a clearing bank.

See R. Trow-Smith, *The History of Stevenage* (1958).

**STEVENS**, the name of two U.S. inventors, father and son, who were prominent in developing marine and rail transportation in the 18th and 19th centuries.

**JOHN STEVENS** (1749–1838) was famous for his work in promoting the use of steam power in transportation. Born in New York City in 1749, he graduated from King's College (now Columbia University) in 1768, subsequently studied law, and was admitted to the New York bar in 1771. In 1776 he became a captain in the Revolutionary Army, and later colonel of his own regiment.

After the war, the problem of safe and speedy transportation across the Hudson River drew his interest to the possibilities of steam navigation. He developed designs for boilers and engines that were unique for the time, and in order to protect his inventions he petitioned Congress for a patent law, which he outlined and which was passed as the Patent Law of 1790, the foundation of the present U.S. patent system. In 1803 he received a patent for a multitubular boiler for use in his marine engines. He was the first to apply the principle of steam to screw propulsion for navigation, building in 1804 a steamboat with two underwater screw propellers that successfully crossed the Hudson. He then designed an engine for a paddle-wheeled, low-pressure steamboat, but before the project was completed, Robert Fulton in 1807 successfully launched his steamboat, the "Clermont." Though discouraged, Stevens launched the "Phoenix" several months later, and, since Fulton had received a monopoly grant of navigation rights on the Hudson, Stevens sent the "Phoenix" by sea to Philadelphia, Pa., the first voyage of a steamship on ocean waters. In 1811 he inaugurated the world's first steam-ferry service.

In an effort to apply the principle of steam engines to rail transportation and in order to enlist public support, Stevens published in 1812 an ingenious pamphlet entitled *Documents Tending to Prove the Superior Advantages of Rail-ways and Steam-carriages over Canal Navigation*, which outlined many phases of railway transportation, engineering features, and even construction costs. To prove the feasibility of the steam locomotive, at the age of 76 he designed and built the first American steam locomotive (1825), which ran on a circular track on his estate but was never used for actual service. In 1815 Stevens obtained from the New Jersey legislature the first charter for a railway ever granted in America, but it was not until 1830 that he formed the Camden and Amboy Railroad and Transportation Company, operated by his sons Edwin A. and Robert L. He died in Hoboken, N.J., March 6, 1838. (X.)

**ROBERT LIVINGSTON STEVENS** (1787–1856), noted as a mechanical engineer and ship designer, was born in Hoboken, N.J., on Oct. 18, 1787, the son of John. He designed the false bow for the "New Philadelphia," which so increased the speed of the steamboat that it was able to leave Albany, N.Y., in the morning and reach New York City before nightfall. In 1822 he built the ferryboat "Hoboken" on modern lines, and introduced the piled slip for ferry docks.

In 1830 Stevens designed the "T" railroad rail, now universally used. The famous "John Bull" locomotive, now in the Smithsonian Institution, was built to his specifications. He added the pilot and bogie trucks to locomotives and increased the number of driver wheels to eight in order to obtain better traction. He discovered that rails laid on log ties with crushed stone or gravel between

them provided a more serviceable and comfortable roadbed than any previously used. He also invented the rail spike.

In 1844 Stevens, an ardent yachtsman, designed the "Maria," for 20 years the fastest yacht afloat. He died at Hoboken, N.J., April 20, 1856. (S. C. Ha.)

**STEVENS, ALFRED GEORGE** (1817–1875), English designer, painter, and sculptor, notable for the Michelangelesque vigour of his work, was born on Dec. 30, 1817, at Blandford, Dorset. He traveled in Italy, 1833–42, spending a year under Bertel Thorvaldsen (*q.v.*) in Rome. In 1845–47 he taught at the new School of Design, Somerset House, London, and in 1850–52 designed cast-metal hearth furniture, stoves, etc., for Hoole and Company, Sheffield, some of which attracted attention at the 1851 Great Exhibition. In the 1857 competition for the Wellington monument in St. Paul's Cathedral, London, he was placed sixth, though his design was the only one adapted to the nave arch under which the monument was to stand.

In 1862, however, Stevens was given the commission and, despite vicissitudes, the complex marble structure with its allegories and bronze equestrian statue was nearly complete at his death (in Hampstead, London, May 1, 1875). For Dorchester House, London, Stevens carried out decorations in 1858–62 (caryatid mantelpiece and many drawings for Dorchester House and other projects now in the Tate Gallery, London), and these best display the freshness he brought to his forms. Stevens also painted portraits (*e.g.*, "Mrs. Leonard Collman," 1854, National Gallery, London), but is probably best remembered for his red chalk figure drawings.

**STEVENS, THADDEUS** (1792–1868), U.S. political leader was one of the most influential Radical Republicans after the Civil War. He was born in Danville, Vt., on April 4, 1792. After graduating from Dartmouth College in 1814, he moved to Pennsylvania, where he taught school and studied law until he was admitted to the bar (in Maryland). He practised as a lawyer in Gettysburg, Pa., from 1816 to 1842 and in Lancaster, Pa., from 1842 until his death. Meanwhile, he invested heavily in real estate and in the charcoal-iron business. An Anti-Masonic member of the Pennsylvania legislature between 1833 and 1842, he made himself conspicuous as a friend of banks, internal improvements, and public schools, and as a foe of Freemasons, Jacksonians, and slaveholders. A Whig congressman in the U.S. House of Representatives from 1849 to 1853, he advocated tariff increases and opposed the compromise measures of 1850, especially the fugitive-slave law. He joined the new Republican Party and from 1859 to 1868 again served in the House of Representatives, where he became, as James G. Blaine afterward said, "the natural leader, who assumed his place by common consent." He exerted this leadership by means of his sarcastic eloquence, his parliamentary skills, and his privileges as chairman of the Ways and Means Committee and later of the Appropriations Committee.

During the Civil War Stevens sponsored legislation for the issue of inconvertible paper money (greenbacks) and for other revenue measures. During the immediate postwar period he was one of the most extreme of the so-called Radical Republicans. He argued that the seceded states, having been defeated in war, were in the condition of "conquered provinces," to which the restraints of the constitution did not apply. When Congress met in December 1865 Stevens took the lead in excluding the senators and representatives from the South. As a member of the joint Committee on Reconstruction, he had an important part in the preparation of the 14th Amendment and the reconstruction acts of 1867. He introduced the resolution for the impeachment of Pres. Andrew Johnson and served as chairman of the committee appointed to draft the impeachment articles. Throughout this period Stevens urged that southern plantations be taken from their owners and that part of the land be divided among the freedmen, the rest of it to be sold and the proceeds to be used toward paying off the national war debt; however, he failed to gain Congressional support for the

cabinet rank and the title of ambassador. He served in this position until his sudden death in London on July 14, 1965.

In 1928 Stevenson married Ellen Borden, who divorced him in 1949. They had three sons, Adlai Ewing III, Borden, and John Fell. Adlai Ewing III led the Democratic ticket for the Illinois legislature in 1964 and was elected state treasurer in 1966.

Among Stevenson's published works were *Major Campaign Speeches of Adlai E. Stevenson*, 1952 (1953), *Call to Greatness* (1954), *What I Think* (1956), *The New America* (1957), *Friends and Enemies* (1959), *Putting First Things First* (1960), and *Looking Outward: Years of Crisis at the United Nations* (1963).

(W. McC. B.)

**STEVENSON, ROBERT LOUIS BALFOUR** (1850–1894), Scottish novelist, essayist and poet, was born at Edinburgh on Nov. 13, 1850, only son of Thomas Stevenson, prosperous civil engineer, and his wife Margaret Isabella Balfour. His poor health made regular schooling difficult, but he did attend Edinburgh academy and other schools before entering Edinburgh university at the age of 16. There he was expected to prepare himself for the family profession of lighthouse engineering. But Stevenson had no desire to be an engineer, and he eventually agreed with his father, as a compromise, to prepare instead for the Scottish bar.

He had early shown a desire to write, and once in his teens he set himself deliberately to learn the writer's craft by imitating a great variety of models in prose and verse. His youthful enthusiasm for the Covenanters led to his writing *The Pentland Rising*, his first printed work. During his years at the university he rebelled violently against his parents' religion and set himself up as a liberal Bohemian who abhorred the cruelties and hypocrisies of bourgeois respectability.

In 1873, in the midst of painful differences with his father, he visited a married cousin at Cockfield, Suffolk, where he met Sidney Colvin, who became a lifelong friend, and Mrs. Fanny Sitwell (the future Lady Colvin). Mrs. Sitwell, an older woman of charm and talent, drew the young man out and won his confidence. Soon Stevenson was deeply in love, and on his return to Edinburgh wrote her a series of letters in which he played the part first of lover, then of worshiper, then of son. One of the several names by which Stevenson addressed her in these letters was "Claire,"

a fact which many years after his death was to give rise to the erroneous notion that Stevenson had had an affair with a humbly born Edinburgh girl of that name. The passion modulated eventually into a lasting friendship.

Later in 1873 Stevenson suffered severe respiratory illness and was sent to the French Riviera, where Colvin later joined him. He returned home the following spring. In July 1875 he was called to the Scottish bar, but he never practised. Stevenson was frequently abroad, most often in France. Two of these journeys produced *An Inland Voyage* (1878) and *Travels With a Donkey in the Cevennes* (1879). His career as a writer developed slowly. His essay "Roads" appeared in the *Portfolio* in 1873, and in 1874 "Ordered South" appeared in *Macmillan's*, a review of Lord Lytton's *Fables in Song* appeared in the *Fortnightly*, and his first contribution (on Victor Hugo) appeared in the *Cornhill*, then edited by Leslie Stephen. It was these early essays, carefully wrought, quizzically meditative in tone, unusual in sensibility, that first drew attention to Stevenson as a writer.

Stephen brought Stevenson into contact with Edmund Gosse, who became a good friend, and later, when in Edinburgh, Stephen introduced him to W. E. Henley. Henley and Stevenson became warm friends, and remained so until 1888, when a letter from Henley to Stevenson containing a deliberately implied accusation of dishonesty against the latter's wife precipitated a quarrel which

Henley, jealous and embittered, perpetuated after his friend's death by a venomous review of Graham Balfour's biography.

While staying at Fontainebleau in 1876 Stevenson met Fanny Vandegrift Osbourne, an American lady separated from her husband, and the two fell in love. Stevenson's parents' horror at their son's involvement with a married woman subsided somewhat when Mrs. Osbourne returned to California in 1878, but it revived with greater force when Stevenson decided to join her in Aug. 1879. Stevenson arrived in California ill and penniless (the record of his arduous journey appeared later in *The Amateur Emigrant*, 1895, and *Across the Plains*, 1892). His adventures, which included coming very near death and eking out a precarious living in Monterey and San Francisco, culminated in marriage to Fanny Vandegrift (divorced from her first husband) early in 1880. About the same time a telegram from his relenting father offered much-needed financial support, and after a honeymoon by an abandoned silver mine (recorded in *The Silverado Squatters*, 1883) the couple sailed for Scotland to achieve reconciliation with the Thomas Stevensons.

Soon after his return Stevenson went, on medical advice (he had tuberculosis), to Davos in Switzerland, accompanied by his wife and his stepson, Lloyd Osbourne. They left there in April 1881 and spent the summer in Pitlochry and then in Braemar. There, in spite of bouts of illness, Stevenson embarked on *Treasure Island* (begun as a game with Lloyd), which started as a serial in *Young Folks*, under the title *The Sea-Cook*, in Oct. 1881. Stevenson finished the story in Davos, to which he returned in the autumn, and then started on *Prince Otto* (1885), a more complex but a less successful work. *Treasure Island* is an adventure presented with consummate skill, with atmosphere, character and action superbly geared to each other. The book is both a "rattling good yarn" for boys and a wry comment on the ambiguity of human motives.

In 1881 Stevenson published *Virginibus Puerisque*, his first collection of essays, most of which had appeared in the *Cornhill*. The winter of 1881 he spent at a chalet in Davos. In April 1882 he left Davos, but a stay in the Scottish Highlands, while it resulted in two of his finest short stories, "Thrawn Janet" and "The Merry Men," produced lung hemorrhages and in September he went to the south of France. There the Stevensons finally settled at a house in Hyères where, in spite of intermittent illness, Stevenson was happy and worked well. He revised *Prince Otto*, worked on *A Child's Garden of Verses* (first called *Penny Whistles*), and began *The Black Arrow*, a piece of "tushery" for *Young Folks*. In May 1885 he was again critically ill. On his recovery he went to England and eventually settled in Bournemouth. The Stevensons lived at Bournemouth from Jan. 1886 until July 1887, during which period his frequent bouts of dangerous illness proved conclusively that the British climate, even in the south of England, was not for him. The Bournemouth years were fruitful, however. There he got to know and love Henry James. There he revised *A Child's Garden* (first published in 1885) and wrote "Markheim," *Kidnapped* (1886) and *The Strange Case of Dr. Jekyll and Mr. Hyde* (1886). The poems in *A Child's Garden* represent with extraordinary fidelity an adult's recapturing of the emotions and sensations of childhood: there is nothing quite like them in English literature. In *Kidnapped*, the fruit of his researches into 18th-century Scottish history and of his feeling for Scottish landscape history, character and local atmosphere mutually illuminate one another. But it was *Dr. Jekyll*—both moral allegory and thriller—that established his reputation with the ordinary reader.

In Aug. 1887 Stevenson set out for America with his wife, mother and stepson, still in search of health. On arrival at New York, he found himself famous, with editors and publishers offering lucrative contracts. He stayed for a while in the Adirondacks, where he wrote essays for *Scribner's* and began *The Master of Ballantrae* (1889). This novel, another exploration of moral ambiguities, contains some of Stevenson's most impressive writing, but it falls away in the contrived conclusion.

In June 1888 Stevenson, with his wife, his mother and his stepson, sailed from San Francisco in the schooner yacht "Casco," which he had chartered, on what was intended to be an excursion for health and pleasure; but in fact he was to spend the rest of his

BROWN BROTHERS

ROBERT L. STEVENSON

life in the South Seas. They went first to the Marquesas, then to Fakarava atoll, then to Tahiti, then to Honolulu where they paid off the "Casco" and stayed nearly six months, leaving in June 1889 on the trading schooner "Equator" for the Gilberts and then to Samoa, where he spent six weeks.

During his months of wandering around the South Sea islands Stevenson made intensive efforts to understand the local scene and the inhabitants. As a result, his writings on the South Seas (*In the South Seas*, 1896; *A Footnote to History*, 1892) are admirably pungent and perceptive. He was writing first-rate journalism, deepened by the awareness of landscape and atmosphere such as that so notably rendered in his description of the first landfall at Nukú Hiva, in the Marquesas. Once, in his violent *Father Damien* (1890), passionately defending the memory of the priest who had given his life in the service of the lepers and as passionately attacking the Rev. Dr. Hyde, his detractor, Stevenson wrote in a wholly personal tone about South Seas affairs.

In Oct. 1890 he returned to Samoa from a voyage to Sydney, and established himself at Vailima, his house in Samoa, with patriarchal status, with his wife, mother, stepson and stepdaughter. The climate suited him; he led an industrious and active life; and when he died suddenly on Dec. 3, 1894, it was of a cerebral hemorrhage, not of the long-feared tuberculosis. His work during these years was moving toward a new maturity. While *Catriona* (U.S. title, *David Balfour*; 1893) marks no advance in technique or imaginative scope on *Kidnapped*, to which it is a sequel, *The Ebb-Tide* (1894), a grim and powerful tale written in a style of studied neutrality (it was a complete reworking of a first draft by Lloyd Osbourne) shows that Stevenson had reached an important transition in his literary career. The next phase was demonstrated triumphantly in *Weir of Hermiston* (1896), the unfinished masterpiece on which he was working on the day of his death. *The Beach of Falesa* (first published 1892; included in *Island Nights' Entertainments*, 1893), a story with a finely wrought tragic texture, as well as the first part of *The Master of Ballantrae*, pointed in this direction, but neither approaches *Weir*. Drawing on the scenery of the Lowland hills and of Edinburgh for setting, using the character of Lord Braxfield as a central figure to set off the sensitive hero, his son; bringing in those plangent overtones of tragic destiny to be found in the Scottish border ballads—Stevenson achieved in this work a remarkable richness of tragic texture in a style stripped of all superfluous fat. The dialogue contains some of the best Scots prose in modern Scottish literature. Fragment though it is, *Weir of Hermiston* stands as a great work and Stevenson's masterpiece.

Stevenson was an indefatigable letter writer and his letters (edited by Sidney Colvin in 1899) provide a lively and enchanting picture of the man and his life. But Colvin omitted many of the most interesting letters, and compressed and dovetailed others, with the result that many important facts about Stevenson's emotional life remained unknown until the true text of all the letters was available. Colvin presented Stevenson's letters to Mrs. Sitwell to the Advocates' library (now the National Library of Scotland) with the proviso that they were not to be used until 1949; the revealing and often fascinating letters to Charles Baxter, given by Baxter to the Savile club, were much later acquired by Edwin Beinecke who deposited them (along with much other Stevenson material) in the Yale university library. Stevenson's biography suffered from his early canonizing; later writers built up a counter-picture, which eventually emerged as that of an immoral swaggerer restrained into reluctant respectability by a jealous wife. Access to the crucial letters yielded a picture of a Stevenson who is neither the "seraph in chocolate" against whom Henley protested, nor a low-living rake, nor an optimistic escapist, nor the happy invalid, but a sensitive and intelligent writer who had no illusions about life and wryly made the best of a world to which he did not profess to have the key.

His literary reputation has also fluctuated. The reaction against him set in soon after his death: he was considered a mannered and imitative essayist, or only a writer of children's books. But eventually the pendulum began to swing the other way, and by the 1950s his reputation was established among the more discerning

as a writer of originality and power; whose essays at their best are cogent and perceptive renderings of aspects of the human situation; whose novels are either brilliant adventure stories with overtones of moral subtlety or original and impressive presentations of human action in terms of history and topography as well as psychology; whose short stories produce some new and effective permutations in the relation between romance and irony or manage to combine horror and suspense with moral diagnosis; whose poems, though not showing the highest poetic genius, are often skillful, occasionally (in his use of Scots, for example) interesting and original, sometimes (in *A Child's Garden*) valuable for their exhibition of a special kind of memory or sensibility.

Stevenson's other works include: *New Arabian Nights* (1882); *Familiar Studies of Men and Books* (1882); *Memories and Portraits* (1887); *Underwoods* (poems) (1887); *St. Ives*, completed by Sir A. Quiller Couch (1897). Stevenson's *Collected Poems* were edited by Janet Adam Smith (1950). The letters were edited by Sidney Colvin in 1899; see also *Vailima Letters*, to Sidney Colvin (1895) and, of great interest and importance, *R. L. S.: Stevenson's Letters to Charles Baxter*, ed. by De Lancy Fergusson and Marshall Waingrow (1956).

**BIBLIOGRAPHY.**—Bibliographies of the works of Stevenson were published by J. S. Slater (1894) and W. F. Prideaux (rev. by J. F. Livingston, 1917). See also *The Stevenson Collection of E. J. Beinecke, a Catalogue*, comp. by George L. Mackay (1950-52). Among the biographies and critical studies are Graham Balfour, *The Life of Robert Louis Stevenson* (1901); Rosaline Masson, *I Can Remember Robert Louis Stevenson* (1922); Lloyd Osbourne, *An Intimate Portrait of R. L. S.* (1924); G. S. Hellman, *The True Stevenson* (1925); G. K. Chesterton, *Robert Louis Stevenson* (1928); J. A. Smith, *R. L. Stevenson* (1927); Henry James and Robert Louis Stevenson (1948); A. B. Fisher, *No More a Stranger* (1946); David Daiches, *Robert Louis Stevenson* (1947); A. R. Issler, *Happier for His Presence* (1949); J. C. Furnas, *Voyage to Windward* (1951); Fanny Osbourne Stevenson, *Our Samoan Adventure*, with a diary by Mrs. Stevenson (1955). (D. Ds.)

**STEVIN (STEVINUS), SIMON** (1548-1620), Dutch mathematician, who helped standardize the use of decimal fractions, was born in 1548 at Bruges and died in 1620, either at The Hague or in Leiden. He was director of the department for roads and waterways, and afterward quartermaster general. Stevin was known to his contemporaries by his military methods and inventions; he invented a defense by a system of sluices to release water through the dikes to flood land before the enemy which was of great importance to Holland. He also invented a carriage with sails which was used on the seashore and carried 26 passengers.

In his *Statics and Hydrostatics* (1586), he enunciated the important theorem of the triangle of forces. This gave a new impetus to the study of statics, which had previously been founded on the theory of the lever. He discovered the hydrostatic paradox that the downward pressure of a liquid is independent of the shape of the vessel, and depends only on its height and base.

In 1586 he published a pamphlet of a few pages, *Thiende*, in which he treated decimal fractions. Decimal fractions and fractions had been employed for the extraction of square roots five centuries before his time, but no one before Stevin had established their daily use. He declared that the universal introduction of decimal coinage, measures and weights would be only a question of time. His notation is rather unwieldy. He printed little circles round the exponents of the different powers of one-tenth. For instance,  $237\frac{578}{1000}$  was printed  $237 \textcircled{5} \textcircled{7} \textcircled{8} \textcircled{3}$ .

There are early editions of Stevin's works (1608, 1634); the first four volumes of a Dutch-English edition, with a biography, appeared in 1955-64. (O. OE.)

**STEWART (STUART or STEUART)**, the surname of a Scottish family, the senior branch of which inherited the Scottish and ultimately the English crown. The first spelling of the name was undoubtedly Stewart, the old Scots version, but during the time of Mary, queen of Scots, when there was much intercourse with France, Stuart and Steuart were adopted owing to the absence of the letter W in the French alphabet.

The family can be traced back to 11th-century Brittany, where for at least four generations they were stewards to the counts of Dol. ALAN, the 4th steward of Dol, was a favourite of Henry I of England and is mentioned in English records as sheriff of

Shropshire from 1101. His younger sons WILLIAM (d. 1160) and WALTER FITZALAN (d. 1177) both held land in England; William, the second son, being lord of Oswestry and an ancestor of the earls of Arundel, his grandson JOHN FITZALAN (d. 1267) becoming "earl" of Arundel in 1243. Walter, the third son, in about 1136 entered the service of David I, king of Scots. He was given extensive estates in the west of Scotland, was appointed steward (or high steward) of Scotland to David, an office which was later confirmed to his family by Malcolm IV in 1157. His grandson WALTER (d. 1241), the 3rd steward, was appointed justiciar of Scotland in 1230 by Alexander II. Walter's eldest son ALEXANDER (1214–1283), the 4th steward, inherited by his marriage to Jean, daughter of James, lord of Bute, the islands of Bute and Arran and in 1263 led the Scots against King Haakon IV of Norway at Largs in Ayrshire.

Alexander had two sons, JAMES (c. 1243–1309), the 5th steward, and JOHN OF BONKYL. James was one of the six guardians appointed to rule Scotland on the death of Alexander III in 1286 in the name of Alexander's granddaughter, the infant Queen Margaret, the Maid of Norway. When Edward I of England established his suzerainty over Scotland in 1291, James became a leading opponent, fighting with William Wallace at the Battle of Stirling Bridge (1297) and supporting Robert I, the Bruce, who was crowned in 1306 as king of Scots. In 1314 James's second son WALTER (1292–1326), the 6th steward, at the age of 21 was placed with Sir James Douglas, "the Good," in command of one of the divisions of the Scottish Army at Bannockburn (1314), where he was knighted by King Robert on the field, and in 1315 he married the king's daughter Marjorie. Their only child ROBERT (1316–90), 7th steward, was declared heir presumptive to his grandfather in 1318, but shortly afterward the king had a son who succeeded in 1329 as David II. On David's death without issue in 1371 Robert, as Robert II, became the first Stewart king, his former title being thereafter held by the heir to the throne as prince and steward of Scotland.

The royal Stewarts had an unlucky history, for of the 14 crowned monarchs 4 were murdered or beheaded, 2 died in battle and 1 in exile, while 7 in succession came to the throne as minors. The direct male line of the family terminated with the death of JAMES V (1512–42). His daughter MARY (1542–87), queen of Scots, was succeeded in 1567 by her only son JAMES VI (1566–1625), who through his father HENRY STEWART, Lord Darnley (1545–1567), son of MATTHEW STEWART, 4th earl of Lennox, a descendant of John of Bonkyl, was also head of the second senior branch of the family. Meanwhile through the marriage of his great-grandparents JAMES IV (1473–1513) and Margaret Tudor, daughter of Henry VII of England, James VI became heir to the English throne, and on the death of Queen Elizabeth I in 1603 was proclaimed king of England as James I.

By the usurpation of Oliver Cromwell and the execution of James's son CHARLES I (1600–1649) the Stuarts were excluded from the throne until the restoration of his son CHARLES II (1630–1685) in May 1660. On the death of Charles II without legitimate issue, his brother JAMES (1633–1701) ascended the throne as James VII of Scotland and II of England, but he so alienated the sympathies of his subjects that after three years an invitation was sent to William, prince of Orange, to come "to the rescue of the laws and religion of England." MARY (1662–1694), James's elder daughter and next in line to her infant half brother JAMES (1688–1766), the Old Pretender, had married William, prince of Orange, son of Charles II's sister MARY (1631–1660), and they were proclaimed joint sovereigns as William III and Mary II of England on Feb. 13 and of Scotland on April 11, 1689. They left no issue and the Act of Settlement (1701), excluding Roman Catholics from the throne, secured the succession to ANNE (1665–1714), second daughter of James II, and, on her death without issue, to Sophia, electress of Hanover and her heirs, descended from Princess ELIZABETH (1596–1662), daughter of James VI and I, who married Frederick V, elector Palatine. James, the Old Pretender, had two sons, CHARLES EDWARD (1720–1788), the Young Pretender, known as Bonnie Prince Charlie, who died without legitimate issue, and HENRY (1725–1807), a

cardinal and titular duke of York. With Henry, who on his death left his grandfather's coronation ring to George III, the legitimate male line of royal Stuarts came to an end. In the female line and senior to the House of Hanover was the royal House of Bavaria, descended from HENRIETTA ANNE (1644–1670), youngest daughter of Charles I, of whom the present head is Albrecht (1905– ), duke of Bavaria (see JACOBITES).

Apart from the royal Stewarts there were in Scotland many families of the name and there are few districts with which they have not been associated. The form of spelling of the name used by particular families is a matter of individual choice and does not necessarily indicate a special descent. As there is no legitimate heir male of the royal house, the families can be divided into two categories, the legitimate but preroyal, being those who came off the main stem before they became kings; and the royal but illegitimate descendants of the Stewart kings. From the first came, among others, the earls of Lennox, Galloway, Atholl, Traquair, the lords of Lorne, and Stewarts of Appin and Ardsheal, all descending from John Stewart of Bonkyl; the Stewarts of Ardvorlich and others who descend from ROBERT (c. 1340–1420), 1st duke of Albany and guardian of Scotland, brother to Robert III; and the Stewarts of Garth and others from the illegitimate issue of a third brother ALEXANDER (d. c. 1405), known as "the Wolf of Badenoch." From the second came, among others, the earls of Moray, and the marquesses of Bute. The Stewart descent is remembered in heraldry by variations either of the blue and silver fess chequy which was borne by the high stewards or of the rampant lion of the royal arms of Scotland.

**STEWART, DUGALD** (1753–1828), Scottish philosopher, was one of the principal exponents of the philosophy of common sense (see further COMMON SENSE, PHILOSOPHY OF). He was born on Nov. 22, 1753, in Edinburgh, where his father, Matthew Stewart (1715–1785), was professor of mathematics. Dugald Stewart was educated at Edinburgh and Glasgow, began university teaching at the age of 19, and, from 1775, discharged all the duties of his father's professorship. In 1785 he succeeded Adam Ferguson in the chair of moral philosophy, which he held until 1820, although after 1809 ill health prevented him from performing his professorial duties. He died at Edinburgh on June 11, 1828.

Stewart's philosophy had little originality and was almost wholly a reproduction of the views of his master, Thomas Reid (q.v.). He was, however, a particularly brilliant exponent of the views of Reid and the common sense school and his classes at Edinburgh enjoyed great popularity. His principal work was *Elements of the Philosophy of the Human Mind* (3 vol., 1792, 1814, 1827); he also wrote *Outlines of Moral Philosophy* (1793); *Philosophical Essays* (1810); and *Philosophy of the Active and Moral Powers of Man* (1828). An edition of his complete works was prepared by Sir William Hamilton, 11 volumes (1854–58).

**STEYN, MARTINUS THEUNIS** (1857–1916), president of the Orange Free State, South Africa, from 1896 to 1901. He was born at Winburg, Orange Free State, on Oct. 2, 1857. Educated at the Grey College, Bloemfontein, and at Deventer in Holland (1877–79), he was called to the bar from the Inner Temple, London, in 1882. After practising as an advocate at Bloemfontein, he became state attorney and then a judge on the Free State bench in 1889.

Steyn defeated J. G. Fraser, chairman of the *Volksraad*, in the presidential election of February 1896. In the turbulent political atmosphere after the raid of L. S. Jameson (December 1895; see TRANSVAAL: History), he stood for closer ties with the Transvaal and as a defender of Dutch language rights against erosion by immigrant influences. In 1897 he concluded an alliance with the Transvaal. Ever watchful of Afrikaner solidarity, Steyn never

theless strove for peace during the crisis of 1899 between Great Britain and the Transvaal, acting as host for the abortive Bloemfontein conference in June. He did not offer unequivocal support to the Transvaal until September, and did so then in the conviction that its cause was just. In the South African War (1899–1902) he fought to the bitter end and regretted the opening of peace negotiations in 1902.

The war ruined Steyn's health, and he never held political office again. After three years' medical care in Europe, however, he returned to the Orange River Colony in 1905 and became a power behind the scenes, opposing Louis Botha's conciliation policy in the Transvaal. He mellowed sufficiently to take part in the National Convention (1908–09), which led to the Union of South Africa (1910), but he lived to witness the Afrikaner rebellion of 1914, when his offer to mediate between the rebels and Botha proved unacceptable to the latter. He died at Bloemfontein on Nov. 28, 1916. See also ORANGE FREE STATE: History.

**STEYR**, a town in the province of Upper Austria at the confluence of the Enns and Steyr rivers, 22 mi. (35 km.) SSE of Linz by road. Pop. (1961) 38,306. Steyr consists of an ancient centre and modern suburbs. In its old square, market place and narrow streets are many Gothic, Renaissance, and Baroque buildings, including the Bummerlhaus and St. Stephen's church (15th century), the museum (17th century), and the town hall (18th century). The castle was restored in the 17th and 18th centuries. In medieval times Steyr was the centre of Austria's iron industry. Present-day manufactures include trucks, automobiles, tractors, ball bearings, sporting guns, and iron goods.

(W. H.)

**STIBNITE**, a mineral consisting of antimony sulfide, is an important ore of antimony. The powdered mineral was used by the ancients for darkening the eyebrows to increase the apparent size of the eyes. In addition to its use as an ore of antimony, it is employed in the manufacture of matches, fireworks and percussion caps. The formula of stibnite is  $Sb_2S_3$ . The crystals are prismatic in habit, longitudinally striated and usually terminated by acute pyramidal planes. There is a perfect cleavage parallel to the length of the crystals, and the basal plane is a plane of gliding; it is the latter property that facilitates the bending of the crystals, and stibnite crystals are often found in a deformed condition. The colour is lead gray and the lustre is metallic and brilliant; crystals become dull on prolonged exposure to light. The mineral is quite soft; hardness is 2 and specific gravity is 4.6. Thin flakes of the mineral transmit a small amount of red light, but are more transparent in the infrared. Stibnite is a photoconductive material which shows maximum sensitivity at 770 mμ.

**STICK INSECT (WALKING-STICK)**, an insect of the family Phasmatidae, so named because of its resemblance to twigs of trees and shrubs upon which most phasmids live and feed. The body and legs are long and slender, and the protective resemblance to twigs is enhanced by the usually brown, gray, or green coloration and the immobile attitudes assumed. Some species are further protected by an armature of sharp spines. Many are wingless; winged species have short, leathery wing covers (tegmina), but the hind wings are often large and beautifully coloured, though usually kept folded over the abdomen. As in the leaf insects (q.v.), to which phasmids are closely allied, the eggs closely resemble seeds. Stick insects at-

EDWIN WAY TEALE

AMERICAN STICK INSECT (DIAPHEROMERA FEMORATA), COMMONLY KNOWN AS WALKINGSTICK, FEEDING ON LEAF

tain their largest size and greatest profusion of species in the tropics: certain Asiatic *Palophus* and East Indian *Pharnacia* grow to be more than a foot long. A few smaller forms occur in southern Europe, and about 25 species are known from the United States, among them *Diapheromera femorata*, which, during heavy infestations, may defoliate oak forests. Phasmids freely regenerate amputated legs and antennae; under certain conditions the stump of an antenna will regenerate a leg.

(T. H. HL.)

**STICKLEBACK**, a small, aggressive bony fish with stout, pointed spines along the midline of the back, in front of the soft dorsal fin. Sticklebacks belong to the family Gasterosteidae. They occur in fresh and brackish waters as well as in coastal waters of the North Temperate Zone. The majority have a compressed, torpedo-shaped body, which in the marine species is longer. The mouth is moderately wide, oblique, and has small teeth. The head is protected by hard bone, the body by a series of bony plates along the sides. The spines are formed from the first dorsal fin; the ventral fins also include a stout erectile spine.

Sticklebacks are short-lived fishes, said to reach an age of three or four years. The widely distributed three-spined stickleback (*Gasterosteus aculeatus*) is a common and well-studied member of the family. It is green to brown above, blending to silvery on the belly, but in spring, at the start of the breeding season, the male displays a bright red belly and becomes active in the preliminaries to mating. He selects a territory and fashions a nest of stems of aquatic plants, which he binds together using a threadlike secretion from a part of his kidney. The male fiercely defends his territory against other males but actively invites females—often employing threats to drive them into his nest to lay eggs. He jealously guards the relatively large eggs, which begin to hatch after ten days, and cares for the hatchlings for a few days of their existence.

About 12 species of sticklebacks are known. The three-spined stickleback is found everywhere in the northern part of the Northern Hemisphere; in North America it occurs as far south as the Virginia coast. The nine-spined stickleback (*Pungitius pungitius* or *Pygosteus pungitius*) rarely exceeds two inches in length and may have 9 or 10 spines, rarely up to 13; its range nearly coincides with that of the preceding species but is more polar. The American, or four-spined, stickleback (*Apeltes quadracus*) is common along the North American east coast from Labrador to Virginia; it is commonly about one and one-half inches long. The sea, or fifteen-spined, stickleback (*Spinachia spinachia*), which attains a length of seven inches, is common along the British and European coasts.

**STIEGLITZ, ALFRED** (1864–1946), U.S. photographer, who devoted his life first to a fight for photography as an art, then to introducing modern painting to the United States, was born in Hoboken, N.J., on Jan. 1, 1864. Stieglitz was educated in New York and Germany, where he began photographing at the age of 19. His earlier work (c. 1883–1910), characterized by constant innovations believed impossible (e.g., the first successful snow photographs), won over 150 important prizes. Having achieved public fame, his experimentation changed from preoccupation with techniques and wide subject matter to intense concentration on material closest to daily life. Two series, over 400 prints each (1917–37), are often considered his greatest photographs: the portrait of Georgia O'Keeffe (his wife) and the "Equivalents." His photographic prints were the first that U.S. museums acquired and housed with other graphic arts.

Stieglitz believed passionately that America could give rise to great works of art. His fostering of the work of others paralleled his own creative work, and is demonstrated through over 175 exhibitions in his three galleries (1905–46), many of which offered the public its first sight of modern art. Starting with Rodin and Matisse exhibitions in 1908 at his "291" gallery, Stieglitz followed with many other first U.S. exhibitions of equally important works (e.g., African Negro sculpture as art, Cézanne, Picasso, Toulouse-Lautrec and others). When the public accepted modern European art, Stieglitz concentrated on U.S. artists, especially the five he showed most often in later years: Demuth, Dove, Hartley, Marin

and O'Keeffe. *Camera Work* (1903–17), edited and published by Stieglitz, documents the history of these stormy years. He died on July 13, 1946, in New York city. (Ds. Br.)

**STIEGLITZ, JULIUS** (1867–1937), U.S. chemist, was a pioneer in recognizing the value of the electron theories of valence to the interpretation of the behaviour and structure of organic compounds, and in applying to organic chemistry the methods and principles of physical chemistry. Born May 26, 1867, in Hoboken, N.J., he received his early schooling in New York, before attending the *Realgymnasium* in Karlsruhe, Ger., from 1881 to 1886. In 1889 he was awarded the Ph.D. in organic chemistry by the University of Berlin, where he had worked under Ferdinand Tiemann. Most of his professional career was spent at the University of Chicago, where he was chairman of the department of chemistry from 1915 to 1933. He was influential in the university as a whole as well as in the American Chemical Society, of which he was president in 1917. He died in Chicago, Jan. 10, 1937.

Stieglitz' research in organic chemistry dealt with four major topics: molecular rearrangements, for which he won the Gibbs medal in 1923; homogeneous catalysis; the theory of indicators; and the stereochemistry of organic nitrogen compounds. He was widely known as an inspiring teacher and, through his text on qualitative analysis (2 vol., 1911–12), the first to base that discipline on the theories of ionization and of chemical equilibrium. (H. I. Sr.)

**STIERNHIJELM, GEORG** (1598–1672), Swedish poet and scholar, often called "the father of Swedish poetry," was born Aug. 7, 1598, at Vika, the son of a miner in Dalecarlia (Dalarna). After studying at Uppsala he spent several years at German universities (Greifswald, Wittenberg, Helmstedt). He returned to Sweden in 1626 and later obtained an official position in Dorpat. In 1631 he was raised to the nobility. From c. 1640 onward he was occasionally in Stockholm, as poet in attendance at the court of Queen Christina, although his home was in Estonia until 1656, when he fled before the Russian invaders. Thereafter he lived in Stockholm in straitened circumstances. In 1661 he was appointed councilor of war and in 1667 director of the college of antiquities. He died at Stockholm, April 22, 1672.

Stiernhielm's first poetic works in Swedish appeared during the 1640s. They included verses in celebration of the queen and three court masques adapted from the French, one of which, *Then Fångne Cupido* (1649), contains fine passages. His most important work is the allegorical, didactic epic, *Hercules* (written c. 1647; published 1658), a fine example of late Renaissance classicism, written in hexameters. Imbued with the spirit of humanism, it is a high-minded sermon on virtue and honour. The theme is developed with power and originality; the imagery is exuberant; the construction faultless. It had great influence on the development of Swedish poetry. Stiernhielm's poems were collected in *Musae Suethizantes* (1668).

Stiernhielm's scholarship was encyclopaedic, and in numerous writings, many unpublished, he dealt with philological, historical and philosophical problems. A great patriot, he claimed that Swedish was man's original language. In his fragmentary works of natural philosophy he expounded a cosmogony based on the platonic, mystical tradition of such thinkers as Paracelsus, Robert Fludd and Comenius.

Stiernhielm's *Samlade skrifter* were edited by J. Nordström, 12 volumes (1924 et seq.).

**STIFTER, ADALBERT** (1805–1868), Austrian narrative writer, one of the first of the middle-class realists. The quiet nobility of his work, with its exaltation of the humble virtues, and the classical purity of his style were only fully appreciated in the 20th century. Stifter was born in Oberplan in the Bohemian forest on Oct. 23, 1805, the son of a linen weaver and flax merchant. His background—the land, and the peasant craftsmen who were his ancestors—was lovingly transfigured in his work. He was educated at the Kremsmünster abbey school and Vienna University, where he matriculated as a law student but mainly attended scientific lectures and took no degree. For some years he made a precarious living as tutor, painter, and writer. From

1840 he began to publish stories in periodicals: *Der Conder* (1840), *Feldblumen* (1841), *Die Mappe meines Urgrossvaters* (1841–42), etc. The inner unity of landscape and people—a marked characteristic of Stifter's work—began to emerge in these stories, markedly in *Brigitta* (1844). *Studien* (1844–50), collections of his early stories in revised form, brought him fame. He followed it with *Bunte Steine* (1853), more stories (*Kalkstein* and *Bergkristall* probably the most compelling of them) with an important preface in which Stifter expounds his doctrine of the "law of gentleness" as the enduring principle.

In 1850 Stifter moved from Vienna, where he had been deeply stirred by political events, to Linz, becoming inspector of schools. In 1857 his great novel *Der Nachsommer* appeared. Like Goethe's *Wilhelm Meister*, of which it was a worthy successor, *Nachsommer* is a novel about the education and growth of a young man. The conquest of passion is here already a thing of the past and the work radiates a still and sun-soaked beauty, with flowing and unhurried pace, and restrained idealism set against the landscape Stifter loved. He then worked ten years on his epic *Witiko* (1865–67), a remarkable book in which medieval Bohemian history is the symbol of man's struggle for a just and peaceful order. Other stories followed (*Nachkommenschaft*, 1864; *Der Waldbrunnen*, 1866), but Stifter was too ill to complete his project of expanding *Die Mappe meines Urgrossvaters* into a novel; only the first volume was finished (1868). He died at Linz, on Jan. 28, 1868.

**BIBLIOGRAPHY.**—*Werke und Briefe*, historical and critical edition by A. Sauer et al. (1901–60); *Gesammelte Werke*, ed. by M. Steff, 6 vol. (1956–57); *Erzählungen in der Urfassung*, ed. by M. Steff, 3 vol. (1950–52). *Biographies*: A. R. Hein, *Stifter*, 2nd ed. (1952); U. Roedl, *Stifter*, 2nd ed. (1958). Modern criticism includes J. Kühn, *Die Kunst A. Stifters*, 2nd ed. (1943); E. P. **STIGAND** (d. 1072), archbishop of Canterbury, is probably Canute's priest of this name whom he placed over the minster of Ashington in Essex in 1020. He was consecrated bishop of Elmham in 1043, but was deposed later in the year when Queen Emma, mother of Edward the Confessor, fell into disgrace, because he was her adviser. He was reinstated in 1044. In 1047 he became bishop of Winchester, and Elmham was given to his brother Aethelmaer. Stigand mediated the peace between King Edward and Earl Godwin in 1052, and was made archbishop of Canterbury in place of the Norman, Robert of Jumièges, who had fled. He did not, however, relinquish Winchester. As he had been intruded into Canterbury while his predecessor was alive, his position was regarded as uncanonical; hence he did not receive the pallium until 1058, and then only from the antipope Benedict X, after whose deposition (1059) Stigand was excommunicated by Nicholas II. His continuance as archbishop was one of the reasons for the papal support given to William the Conqueror's invasion in 1066. Yet he was too powerful for William I to remove him at once, and he was not deposed until 1070. Domesday Book shows him to have had extensive lands and many men committed to him. He held some abbeys in plurality, as well as his two sees. He died on Feb. 22, 1072.

See Sir F. M. Stenton, *Anglo-Saxon England*, 2nd ed. (1947); F. E. Harmer (ed.), *Anglo-Saxon Writs* (1952). (D. Wx.)

**STIGMATIZATION**, in the religious sense, consists of the appearance, on the body of a living person, of wounds or scars ('stigmata') corresponding to those of the crucified Christ—that is, on the hands, feet, and near the heart, and sometimes on the head (crown of thorns) or shoulders and back (carrying of the cross and scourging). Although cases of Protestants and unbelievers are known, the great majority of stigmatists are Roman Catholic mystics, and of these the majority are women. Some stigmatists are canonized saints, but the church, in canonizing a person, seeks proof of sanctity not in extraordinary phenomena such as ecstasies, visions, or stigmatization but in heroic virtue during his lifetime and in miracles after his death. Cardinal Prospero Lambertini (later Pope Benedict XIV) in his classical treatise on beatification

tion and canonization declared that it is theoretically possible that God might accord stigmata to sinners and pagans, because stigmatization is a freely bestowed gift; hence, a person might have stigmata without being holy. Besides, the church in canonizing a stigmatist does not pass judgment on the question whether the stigmata are natural or supernatural. Among the more than 330 known stigmatized persons only some 60 are saints or beati.

Natural stigmata are commonly due to fraud or to auto- or heterosuggestion (see SUGGESTION). Medical and psychological evidence shows that stigmata may be the consequence of a strongly emotional state. Common experience indicates that emotions may be accompanied or followed by bodily changes and disturbances—increased rate of heartbeat, change of facial colour, trembling, sweating. Long-lasting or pathological emotional conditions may cause or aggravate organic disorders or lesions (see PSYCHIATRY: *History: Modern Schools: Psychosomatic Medicine*). Experiments made on hysterical women by the French psychiatrist Pierre Janet and the German physician Alfred Lechler have also shown that strong emotional states may result in such phenomena as bloody tears and stigmata. In these cases the psychophysiologic mechanism is set in motion by suggestion: an experienced psychiatrist or physician may work highly suggestible subjects to such an emotional pitch that the suggested idea of stigmata externalizes itself in their bodies. Since not only the psychophysiologic mechanism but also the initial cause is natural, stigmata so produced are called purely natural.

Roman Catholic authors admit also the possibility and actual existence of supernatural (divine) stigmata. These are stigmata whose initial cause is found in God, inasmuch as God may produce in certain persons an emotional condition that externalizes itself in the body. Stigmata that so result are natural insofar as they are the product of a natural state of emotion, but their initial cause is supernatural. This theory was advanced as early as the 17th century by St. Francis of Sales.

The criteria for deciding whether or not stigmata have divine origin are divinely inspired visions, spiritual fruits such as conversions of other persons, and miracles performed by the stigmatist.

See H. Thurston, S.J., *The Physical Phenomena of Mysticism*, posthumously ed. by J. H. Crehan, S.J. (1952); E. Amman, "Stigmatisation," in *Dictionnaire de théologie catholique*, vol. xiv, col. 2616–24 (1941). (J. H. V. D. V.)

**STILBITE**, a mineral of the zeolite group consisting of hydrated calcium aluminum silicate. The colour is usually white, sometimes red, and on the perfect cleavage (parallel to the plane of symmetry) the lustre is markedly pearly; hence the name stilbite (Gr. *stilbein*, "to shine") given by R. J. Haüy in 1796. After the separation of heulandite from this species in 1818, the name desmine (Gr. *desme*, "bundle") was proposed, and this name is employed in Germany. The composition is  $\text{CaAl}_2\text{Si}_7\text{O}_{18} \cdot 7\text{H}_2\text{O}$ . Usually a small proportion of the calcium is replaced by sodium. Crystals are monoclinic, and are invariably twinned, giving rise to complex groups and characteristic sheaflike aggregates. The hardness is 3.5 and the specific gravity 2.2. Stilbite occurs with other zeolites in the amygdaloidal cavities of basic volcanic rocks; it is sometimes found in granite and gneiss, and exceptionally in metalliferous veins. Beautiful, salmon-pink crystals occur with pale-green apophyllite in the Deccan traps near Bombay and Poona, India; white sheaflike groups encrust the calcite (Iceland spar) of Berufjörður near Djúpvogur, Ice.; and crystals of a brick-red colour are found at Old Kilpatrick, Dumbartonshire, Scot. Good specimens of stilbite have been found in New Jersey and Nova Scotia. See also ZEOLITE.

**STILICHO, FLAVIUS** (c. A.D. 365–408), Roman general, the effective ruler of the Western Roman Empire from 395 until 408, was half-Roman and half-Vandal by birth. He made the army his career and in 383 served on an embassy to the Persian king Shapur III, afterward marrying Serena, the favourite niece of Theodosius I. He was appointed count of the domestics (commanding the emperor's household troops) c. 385, and then, in or before 393, master of both services (i.e., commander in chief of the army), an office which he held until his death.

Little is known of Stilicho's military exploits during the lifetime of Theodosius. It is known that he became the enemy of Rufinus (q.v.) because of a difference of opinion about the treatment of some barbarian invaders in 389. Before his death Theodosius appointed Stilicho and Rufinus to be the guardians of his sons Honorius and Arcadius respectively. Stilicho had a great military advantage over his rival, for the army Theodosius had assembled to crush Eugenius (see THEODOSIUS) was still concentrated in the West under Stilicho's command when Theodosius died on Jan. 17, 395.

Before either Stilicho or Rufinus could attack the other, the Visigoths, who were living in Lower Moesia and who had suffered severe losses in the campaign against Eugenius, rebelled under the leadership of Alaric (q.v.) and began to devastate Thrace and Macedonia. Stilicho, who claimed the prefecture of Illyricum, disputed between the emperors, for the Western government, went with his army to Thessaly. But when he was about to engage Alaric there, he was ordered by Arcadius, acting on Rufinus' advice, to send a number of his troops to Constantinople. Stilicho obeyed and thus enabled Alaric to penetrate into Greece; but the troops who had been sent to Constantinople murdered Rufinus there on Nov. 27, 395. At this time the gifted poet Claudian began to publish his poems in praise of Stilicho, and his works are an important source of information about the politics of the time until 404, when the poet appears to have died (see CLAUDIANUS, CLAUDIUS).

In 397 Stilicho took another army to Greece but failed again to bring Alaric to battle and withdrew to Italy. In that same year Gildo, the count of Africa, rebelled against the Roman government and refused to allow the African grain ships to sail to Rome. Stilicho promptly imported grain from Gaul and Spain. In the following year he sent Mascezel, a brother of Gildo, to Africa with an army. Gildo was easily overthrown and put to death, but Mascezel died soon afterward and Stilicho was suspected of having had him murdered so that he might not become a rival to his own power. In 398 Stilicho's daughter Maria was married to the emperor Honorius, and Stilicho himself became consul in 400.

In 401 Alaric and the Visigoths invaded Italy and threatened Milan, where Honorius was then living. Stilicho summoned troops from the Rhine frontier and from Britain to strengthen his army, and in 402 he engaged the Goths at Pollentia (Pollenzo, near modern Bra). The battle was fought on Easter Sunday, April 6, and although Stilicho's victory was not complete he captured the Gothic camp. Alaric now marched toward Etruria but after negotiations agreed to withdraw from Italy. In 403, however, he entered Italy again and attacked Verona, where Stilicho once more engaged him successfully and pursued him northward toward the Brenner Pass. But again an understanding was reached, and Alaric, though his army was in bad condition, was allowed to escape.

Late in 405 Italy was menaced by new invaders, a vast host of Germans, mainly Ostrogoths, led by a pagan called Radagaisus. Terrified contemporaries believed that they numbered hundreds of thousands, though any such figure is impossible. They attacked Florence, but Stilicho compelled them to withdraw to Fiesole, where he cut off their supplies and massacred them. Radagaisus was executed on Aug. 23, 406, and in celebration of the victory a triumphal arch was erected at Rome, of which the inscription still exists.

Stilicho had never abandoned his aim of annexing the prefecture of Illyricum, and in 407 he was free to put his plans into operation. He closed the ports of Italy to all Eastern ships. He instructed Alaric to hold Epirus for Honorius, and he himself prepared to cross the Adriatic. But a false report reached him that Alaric was dead, and then he heard of the revolt of Constantine (see CONSTANTINE [d. A.D. 411]) in Britain. Once more his plans had to be abandoned. Alaric then marched to the province of Noricum and demanded compensation for the trouble he had been put to. His price was high—4,000 lb. of gold—but in spite of considerable opposition Stilicho persuaded the Senate at Rome to pay it.

By this time the empress Maria had died, but early in 408 Honorius married another daughter of Stilicho, Thermantia. But

Stilicho's influence had declined. It was rumored that he wished to have his son Eucherius elevated to the throne. Reports reached him, however, early in 408 that his army was disaffected. Then came the news of the death of the Eastern emperor, Arcadius, and Stilicho proposed to go to Constantinople. But a certain Olympius, a palace official, spread the rumour that Stilicho was preparing to put his own son on the Eastern throne, with the result that the troops in Ticinum (Pavia) killed nearly all the officials present there on Aug. 13. Stilicho went to Ravenna but was imprisoned on Honorius' orders. He was beheaded on Aug. 22, and Eucherius was put to death shortly after.

(E. A. T.)

**STILL, ANDREW TAYLOR** (1828–1917), founder of osteopathy (*q.v.*), was born in Jonesville, Va., on Aug. 6, 1828. His family moved in 1837 to Macon County, Mo., and later to the Shawnee reservation near Kansas City, Kan. By his own account (*Autobiography*, 1897; revised 1908) Still acquired some medical knowledge from his father and at a college in Kansas City; from 1849 onward he practised in various Kansas and Missouri communities. He took an active part in the antislavery cause in Kansas, and in 1857 was elected to the territorial legislature on the Free State ticket. He served in the Civil War, attaining the rank of major. After the war, and following the deaths of three of his children in an epidemic of cerebrospinal meningitis, Still began searching for means other than those of orthodox medicine to combat disease. After much experimentation he formulated his principles of osteopathy in 1874. He underwent a period of opposition, but finally, in 1892, founded the American School of Osteopathy at Kirksville, Mo., where he died on Dec. 12, 1917.

See Ray G. Hulbert, "Andrew T. Still," *Missouri Historical Review*, vol. xix (1924); E. R. Booth, *History of Osteopathy* (1924); M. A. Lane, *Dr. A. T. Still, Founder of Osteopathy* (1918). (F. L. A.; X.)

**STILLBIRTH:** see ABORTION; FETAL DISORDERS.

**STILL-LIFE PAINTING** may be loosely defined as the depiction of inanimate objects for the sake of their qualities of form, colour, texture and composition. Still life has always existed in painting as a subsidiary element; it occurs in Roman wall decorations at Herculaneum in the 1st century A.D. and again in mosaics (Lateran museum, Rome) of the same date. Four centuries later it appeared as an independent decorative element in the ceiling mosaics at the church of Sta. Costanza, Rome. A significant change came in the 6th century when pure still life disappeared and was replaced by symbols with a specific religious connotation, as exemplified by the two fish on a plate in a mosaic of the Last Supper at S. Apollinare Nuovo, Ravenna. It was not until the rise of a wealthy merchant class, coupled with the prolonged effects of the Reformation, that a new demand grew for secular subjects in painting other than portraiture. Finally, the Renaissance artists' fresh interest in the material details of their environment led to a more naturalistic representation of these as well as of the human figure. Thus Raphael included an admirable still-life group of musical instruments in his "St. Cecilia" (Bologna) and Vittore Carpaccio devoted great care to the still life in his "St. Jerome in his Study" (S. Giorgio dei Schiavoni, Venice). Yet it was the northern artists who provided minutely detailed still life, and the exquisite draftsmanship of Jan van Eyck and of Albrecht Dürer was a part of the northern artistic tradition most suited to the development of still-life painting as a separate art.

However, the first signed and dated pure still life, of a dead partridge, gauntlets and arrow pinned against a wall (Munich), was painted in 1504 by an Italian, Jacopo de' Barbari, working in the north. Early still lifes were produced in Antwerp, where the Dutch painter Pieter Aertsen (1508?–75) spent a considerable part of his working life; a work by an unknown artist, produced in his environment (Boymans Museum, Rotterdam), has all the elements of the genre. On the table are an earthenware pot, a jug, a bowl, a sliced loaf, some pieces of cheese, and several fishes; all these are thrust forward in such a way that the spectator seems to be very close to the table and looking at them from only slightly

above. The artist has concentrated on rendering the forms of the objects, which are accentuated by a strong light coming from a window on the left, but already the observation of tonal values of light and shade irrespective of local colour was becoming the chief preoccupation of the still-life painter. The austerity of this tightly composed painting may be contrasted with the work of Pieter Aertsen himself, who preferred the market stall and the kitchen larder, with their piles of vegetables and fruits, as his subjects. Figures are sometimes put into the background, as in "The Butcher's Shop" of 1551 (Uppsala), but interest is concentrated upon gory sides of beef, sausages, game and fish spread upon slabs or suspended from hooks. The composition is overcrowded; the picture literal to a point of nausea.

Giuseppe Arcimboldo (*c.* 1530–93) made a curious use of still life. Human heads and even whole figures are ingeniously fashioned out of various fruits, vegetables, fish and animals to symbolize the four elements or the four seasons. Examples of these fantasies are in the Vienna art gallery. One of the few great Italian masters to produce pure still life was Michelangelo da Caravaggio (1573–1610), and his still lifes in the Ambrosiana, Milan, and the Kress collection, Washington, D.C., show him to be a formidable rival of the Dutch and Flemish artists. Solidity of form and composition, brilliant colour and precise drawing are united with a superb feeling for light and atmosphere in his work, as in Francisco de Zurbaran's famous still life of 1633. Qualities such as these are the essence of still life; and during the 17th century many Netherlandish painters achieved a competence of this kind rarely surpassed. Mention need only be made of Willem Heda (1594–1680/82) and Willem Kalf (1622–93) who used goblets, nautilus shells, delicate porcelain and rich fabrics for much of their work. Kalf's technique, in particular, resembles Vermeer's; and, indeed, the interiors with figures painted by Vermeer partake strongly of the quality of still life. Kalf's pictures are usually simpler and less crowded than those of Abraham van Beyeren (1620–75), although each relied upon similar subjects, and the inclusion of a partly peeled lemon was a favourite trick with many of these painters. Cornelis de Heem and Jan de Heem were the ablest of a large family of still-life painters, while Jan van Huysum (1682–1749) became pre-eminent as a flower painter, and often set his still life against a landscape background. Frans Snyders (1579–1657), along with Jan Fyt (1611?–61) and Jan Weenix (1640/44–1719) also did this, but chose to paint dead game, sometimes adding live birds and dogs for contrast. Melchior d'Hondecoeter (1636–95) also worked in this tradition.

Nothing of new artistic importance emerged from the Netherlands during the 18th century, for the country had become severely impoverished. Jean Baptiste Siméon Chardin (1699–1779) added peculiarly French qualities of lucidity and penetration to the enhancement of the art. He broke away from the outmoded conventions of A. F. Desportes (1661–1743) and J. B. Oudry (1686–1755), derived from the Netherlands; and the Louvre version of "The Skate" (1728) is notable for its broad treatment and thick, impasted highlights. There is an escape from the airlessness and overcrowding, the emphasis upon the inessential detail to the detriment of the whole, which often mars Dutch and Flemish painting. The figures and objects in a Chardin household seem timeless and inevitable; "La Fontaine" (National gallery, London) and "Le Bénédicité" (Louvre) are paintings that equal, if not surpass, the work of Gerard Terborch and Jan Vermeer.

Something of Chardin's ease and simplicity appears in Francisco Goya's still-life paintings; for example, the "Still-Life With Lamb's Head" in the Louvre; and he, with Chardin, was to inspire 19th-century artists as diverse as I. H. Fantin-Latour and Edouard Manet.

After a momentary eclipse during the neoclassical period, interest in still life was reawakened by Eugène Delacroix's startlingly original "The Stove," painted in the 1830s. Casually composed, the painting shows a corner of the artist's studio with its stove and other bric-a-brac. There is a new quality of high-spirited realism, and even defiance, and it is significant that Paul Cézanne was to paint the same type of composition (Chester-Beatty collection, London) in the fierce, undisciplined style of his youth.

Still life by Jacopo de' Barbari, 1504. 19¼ × 16½ in.

"Shells, Lobster, Vase and Bird," Roman wall painting from Herculaneum, 1st century A.D.

## EARLY STILL LIFE

The challenge posed the artist by the form, colour and texture of inanimate objects has been a major inspirational force in Western art since the 1st-century Roman murals at Herculaneum (above), in which still life played an important but subsidiary role. Still life became an important independent art with the earliest known signed and dated work (left), painted in 1504 by Jacopo de' Barbari, an Italian who lived and worked in the north. The meticulous draftsmanship and fascination for detail that characterized 16th-century northern painting may be seen in the composition below, by an unknown Dutch artist

Still life by an unknown Antwerp master, about 1560-70. 13⅞ × 19⅞ in.

"Basket of Fruit" by Michelangelo da Caravaggio (1573-1610). 18 $\frac{1}{8}$  × 25 $\frac{3}{8}$  in.

"Still Life" by Willem Kalf, (1622-93). 25 $\frac{3}{8}$  × 21 $\frac{1}{4}$  in.

"Summer" by Giuseppe Arcimboldo, 1563. 29 × 19 in.

"The Butcher's Shop" by Pieter Aertsen, 1551.  $48\frac{1}{2} \times 64\frac{1}{2}$  in.

#### 16TH- TO EARLY 19TH-CENTURY STILL LIFE

"Basket of Fruit" by Michelangelo da Caravaggio (Plate II, top) is an oil painting which, in its precision, its solidity, its sense of light and atmosphere rivals the work of 17th-century northern masters like Willem Kalf (Plate II, bottom). The crowded butcher shop scene by Pieter Aertsen (above) shows what was likely to occur when fascination with details was allowed to overcome the northern artists' compositional sense. The 18th-century still life of Jean Baptiste Siméon Chardin (below) and the early 19th-century work by Francisco Goya (right) show a growing interest in the simplification and selection of important details. The fanciful caricature, which makes its own curious use of still-life elements, (Plate II, right) is the work of Giuseppe Arcimboldo, a 16th-century Italian Mannerist.

"Still Life with Lamb's Head" by Francisco Goya, about 1816-24. 18 x 24 in. In the Louvre, Paris

"The Skate" by Jean Baptiste Siméon Chardin, 1728.  $43\frac{1}{4} \times 55$  in. In the Louvre, Paris

"The Stove" by Eugène Delacroix, c. 1830. 20 × 17 in. In the Louvre, Paris

"Vase of Flowers" by Camille Maquet, about 1882. 39½ × 32 in.

"Emblems of Peace" by William Harnett, 1890. 52 × 42 in.

## 19TH-CENTURY STILL LIFE

Still life was largely neglected during the neoclassical period. The bravura realism of Eugène Delacroix's painting "The Stove" (Plate IV, top left), painted in the 1830s, helped to reawaken interest among young artists like Gustave Courbet, one of whose finest still lifes appears at right. The "Vase of Flowers" by Claude Monet (Plate IV, top right) shows the Impressionists' interest in the effects of color and light. Paul Cézanne (below) exploited spatial ambiguity in attempting to resolve one of the basic dilemmas of painting: how best to represent three-dimensional objects on a two-dimensional surface. The meticulously realistic grouping by W. Harnett (Plate IV, bottom) is an example of the Dutch-inspired, U.S. *trompe l'oeil* school.

"Pomegranates" by Gustave Courbet, 1871. 10½ × 13¾ in.

"Still Life with Ginger Jar" by Paul Cézanne, c. 1888-90. 25½ × 32 in. In the Louvre, Paris

"Chair and Pipe" by Vincent Van Gogh, 1888-89. 36 × 28 in.

"Gauguin's Chair" by Van Gogh, 1888. 25 3/4 × 30 3/4 in.

"The Coffee" by Pierre Bonnard, about 1914. 28 × 41 in.

"Still Life: Death's Head, Leeks, and Pot" by Pablo Picasso, 1945. 15 × 20 in.

"Still Life" by Georges Braque, 1925. 15 × 23 in.

"The Window" by Henri Matisse, 1916. 30 × 20 in.

#### LATE 19TH- AND EARLY 20TH-CENTURY STILL LIFE

The two paintings of chairs by Van Gogh (Plate VI, top left and right) show the range of emotion and invention that an inanimate object could produce in that impassioned painter. Both the *Nabis*, as Pierre Bonnard (Plate VI, bottom), and the *Fauves*, as Henri Matisse (right), employed unusual viewpoints and bright colours to produce brilliant two-dimensional patterns. Cubists Pablo Picasso (top) and Georges Braque (above) found in still life an ideal subject for their constructions, made up of complex fragmentations of form and multiple viewpoints

BY COURTESY OF IVAN LE LORRAINE ALBRIGHT

"Poor Room—There Is No Time, No End, No Today, No Yesterday, No Tomorrow, Only the Forever, and Forever, and Forever, Without End" by Ivan Le Lorrain Albright, 1959. Property of the artist

Fantin-Latour's early work is dry and sombre, with the accent upon one bright area, perhaps some roses in a glass, like the Tate gallery painting of 1861. He used a limited palette, and relied upon subtle gradations of tone to obtain plasticity. Influenced by the Impressionists, his colours became richer and his brushwork more lively and impasted, as in the 1881 "Bowl of Flowers" (Lady Lever gallery, Port Sunlight, Cheshire), but at no time did he approach the vigour and immediacy displayed in Gustave Courbet's "Fleurs dans un Panier," 1863 (Cargill collection, London), so reminiscent of Delacroix's painting of 1849, "The Over-turned Flower Basket in a Park" (Wildenstein gallery, New York city). Unhesitatingly, using broad, fluent strokes, Courbet captured the essential features of the objects before him, giving them tangible shape and glowing colour. "Pomegranates," 1871 (Burrell collection, Glasgow), and "The Trout," 1873 (Oeffentliche Kunstsammlung, Zürich), are two of Courbet's most powerful works. Even Manet's "Les Poissons" (Chester-Beatty collection, London), with its cool, brilliant colour, cannot quite rival it.

As might be expected, the still lifes by Claude Monet are flooded with a warm shimmering light. Form and space are revealed more by the acute perception and recording of hitherto unexplored colour harmonies, than by tonal variations and linear perspective.

Cézanne found landscape and still life particularly suited to his own artistic development. Still life acquired a new importance for him, allowing him to concentrate upon the fundamental, recurring problems of form, colour and space, undisturbed by irrelevant anecdotal or literary associations. By 1870, with "Still-Life With Black Marble Clock" (Wildenstein), he showed great originality of conception. Already he was fascinated by the abstract pattern formed by the folds in the tablecloth; the objects on the table, seen at a high eye level, seem to be in the same spatial plane as the clock on the mantelpiece. This spatial ambiguity is even more pronounced in the Louvre "Still-Life With Ginger Jar" (1888-90), where the jar and basket of fruit on the sharply tilted floor seem level with the objects on the table in the foreground. This deliberate use of different eye levels and viewpoints, combined with a slight "flattening" of elliptical shapes (e.g., coffee pot, basket handle), was an attempt to limit the amount of recession into the picture, and to resolve the paradox of representing three-dimensional objects on a two-dimensional surface. Paul Gauguin also used those devices, but emphasized the decorative element, modeling his objects in broad planes of pure, bright colours; a development for which Van Gogh was also partly responsible.

Vincent Van Gogh's intensely personal vision, when applied to still-life painting, could bring a new emotional significance to such mundane objects as a row of peasants' boots, a Bible and a candle, or his "Bedroom Chair" (Tate gallery, London). Here, as in all his work, both the colours and the brush strokes used convey not only shape, but also much of this emotional fire. The contrast between the Tate "Chair" and "Gauguin's Chair" (V. W. Van Gogh collection, Amsterdam), with its fierce clashes of violet, green and red, surely illustrates Van Gogh's extremely wide evocative powers.

At the turn of the century, still-life painting was no longer the province of a few specialists. Between 1907 and 1909, the Cubists, led by Pablo Picasso and Georges Braque, carried Cézanne's ideas much further, and like him found still life to be the subject most suited to their experiments with perspective. Objects were reduced to their basic shapes, split open, flattened and reorganized into a complex, predominantly two-dimensional composition. The images made by the profile, top, bottom and oblique angles of one object might be superimposed upon each other in one painting. This is the so-called analytical Cubism. The colours were restricted to greens, grays and browns. Synthetic Cubism, or collage, came next, and pieces of material, newspapers, etc., were stuck to the board or canvas, and painted into the picture. These are gayer in colour, and often made rather witty visual paraphrases. Braque's "Still-Life" (Tate) of 1925, although still using Cubist formulas, is slightly more naturalistic. Although he worked in a more rigorous abstract style during the 1930s, unlike Picasso he did not use still life to convey violent changes of mood, such as found in the latter's somewhat disquieting "Death's-head with Leeks" (1945).

Contemporary with the Cubists were Henri Matisse, André Derain and Maurice de Vlaminck (*les Fauves*, "the Wild Beasts"), whose work is characterized by radiant colour, great decorative skill and *joie de vivre*. In still life, unusual viewpoints are sometimes chosen, partly for the variety of pattern they afford, and never for the purpose of deliberate distortion. Édouard Vuillard and Pierre Bonnard (*les Nabis*, "the Prophets"), less formalized in style than Matisse, were yet painters of extreme sensitivity and taste.

The Dadaists, and later the Surrealists, stimulated by modern psychoanalytical research, exploited still life in an unusual way. Attempting to explore and record something of the secret working of the subconscious, partially revealed in dreams, they juxtaposed in their paintings animate and inanimate objects which are quite unrelated to each other in normal circumstances. The disconcerting, haunting effect sometimes thus produced is intended as a pictorial approximation to this other (dream) reality. Salvador Dali's "Persistence of Memory," with its melting watches set on a rocky foreshore, is a typical example.

No British artist of note (excepting William Etty), had seriously attempted still life until W. R. Sickert, with the New English Art club, introduced a taste for the genre from France in the 1890s. Matthew Smith, Ben Nicholson, Edward Wadsworth and William Scott are representative modern English exponents.

Still-life painting in the United States stems primarily from the Dutch realist *trompe l'oeil* tradition best exemplified by the work of the Peale family in the early 19th century and continued by William M. Harnett (1848-92). Harnett's reputation was established during the 1880s with works such as "Emblems of Peace" (1890, Springfield [Mass.] museum) in which he depicted commonplace objects with meticulous precision and deceptive realism. Of Harnett's several followers John F. Peto (1854-1907) was the most distinguished, his "Still Life With Lanterns" (Brooklyn [N.Y.] museum) might easily be confused in style with Harnett's "The Old Violin." For nearly 40 years Harnett's work lay forgotten until exhibited in 1939, when American Surrealists soon claimed him as a forerunner, reading into his sly whimsy a more profound psychopathic preoccupation than he could originally have intended. Surrealist overtones are more obvious in the work of Walter Tandy Murch (1907- ), who owes much to Harnett but paints more loosely and introduces a stronger feeling for atmosphere. Murch's "The Circle" (c. 1948, Brooklyn museum) represents an old gramophone seen cornerwise with a dead beetle pinned inconspicuously to an odd corallike object on the turntable. The paintings of Ivan Le Lorraine Albright (1897- ) are very different; he shows an almost overpowering, morbid interest in the minutiae of texture, and in "Self Portrait" (1935, Earle Ludgin collection, U.S.) the flesh seems about to dissolve. Bernard Perlin's "The Jacket" (1951, Whitney museum) represents yet another kind of careful, factual realism.

**STILLMAN, WILLIAM JAMES** (1828-1901), U.S. painter and journalist, was born at Schenectady, N.Y., June 1, 1828, and graduated from Union college, Schenectady, in 1848. He studied art under Frederick E. Church and early in 1850 went to England, where he fell under the influence of Rossetti and Millais. He studied art in Paris, returned to the United States and devoted himself to landscape painting on upper Saranac lake in the Adirondacks and in New York city. There also he started the *Crayon*; when it failed for want of funds, Stillman moved to Cambridge, Mass. He returned to England, and afterward painted with Ruskin in Switzerland. He was in Normandy in 1861 when the American Civil War broke out and was appointed U.S. consul in Rome; he resigned in 1865, but immediately afterward was appointed to Crete. When in London he lived with D. G. Rossetti. When the insurrection of 1875 broke out in Hercegovina he went there as a correspondent of the *Times* (London), and his letters from the Balkans aroused so much interest that the British government was induced to lend its countenance to Montenegrin aspirations. In 1877-83 he served as the correspondent of the

*Times* at Athens; in 1886–98 at Rome. After his retirement he lived in Surrey, where he died on July 6, 1901. He wrote, among other books, *The Cretan Insurrection, 1866–1868* (1874), *On the Track of Ulysses* (1888), *Billy and Hans* (1897) and *Francesco Crispi* (1899). His *Autobiography of a Journalist* was published in 1901.

**STILLWATER**, a city of north central Oklahoma, U.S., 65 mi. N. of Oklahoma City; the county seat of Payne county and the seat of Oklahoma State university. The first recorded mention of Stillwater was on Dec. 25, 1884, when an army officer reported that "about 200 men, armed with double-barreled shot guns and Winchesters," had located there on lands not officially opened to settlement. This was the last serious foray into the Indian territory of "boomers," persons from Kansas who for five years had made raids into the territory in an effort to induce the federal government to open the lands; a detachment of 350 cavalymen forced their surrender in Jan. 1885. A permanent settlement was made in April 1889 in the first great Oklahoma land run. Stillwater was incorporated as a village in 1890 and as a town in 1891; the name is from Stillwater creek, known by that name before any settlement was made. The city gave \$10,000 and 200 ac. of land to secure the Oklahoma Agricultural and Mechanical college, which was opened in the Congregational Church on Dec. 14, 1891. It was renamed Oklahoma State university in 1957. The plant, including a 500,000-volume library, was largely a product of the administration of Pres. Henry G. Bennett, 1928–51. Industrial activity in the Stillwater region includes dairying, beef cattle, wheat and oil. For comparative population figures see table in OKLAHOMA: *Population*.

See B. B. Chapman, *The Founding of Stillwater* (1948). (B. B. C.)

**STILT**, a wading bird related to the avocet, with which it forms the family Recurvirostridae. Two species are generally recognized: the widely distributed common stilt (*Himantopus himantopus*), whose five or more geographic races are sometimes accorded specific rank, and the exclusively Australian banded stilt (*Cladorhynchus leucocephala*). Stilts are remarkable for the extreme length of their slender legs. The head is small, bill dark (and not upturned as in the avocet), neck long, and wings long and pointed. Their calls resemble the yelping of a pup. The black-necked stilt (*H. h. mexicanus*), breeding from the northwestern and southeastern U.S. to northern South America, winters from the southern U.S. to the southern limits of the breeding range. Its legs and the iris of the eye are reddish; wings and upper back, including the crown, are black; and underparts from throat to rump are white. This stilt builds a simple grassy nest on the edge of a pool or lake, where it can forage for its prey:

crustaceans, insects, and other small animals. The clutch of three to five buffy and spotted eggs, laid in late spring, are incubated for almost a month by both parents; the young, brownish and down-clad, leave the nest soon after hatching. The banded, or red-breasted, stilt, with chestnut chest band, yellow legs, and brown iris, nests along inland marshy ponds in the Australian interior.

AMERICAN BLACK-NECKED STILT AT NEST

**STILWELL, JOSEPH WARREN** (1883–1946), U.S. Army officer who commanded in the China, Burma, India (CBI) theatre during World War II. He was born at Palatka, Fla., March 19, 1883, and in 1904 was graduated from the U.S. Military Academy. Stilwell's work with the IVth Corps in combat intelligence during World War I won him the distinguished service medal. After the war he exploited his talent for languages, making Chinese a specialty. Three tours of duty in China followed, during which his abilities as improviser, tactician and trainer impressed Gen. George C. Marshall, U.S. Army chief of staff in World War II. When the United States entered that war in 1941, the War

Department, fearing that China might make a separate peace, ordered Stilwell, with the concurrence of China, to improve the combat efficiency of the Chinese Army, to become chief of an international staff the Chinese then proposed organizing, and to command all U.S. Army forces in China, Burma, and India.

In 1942 Stilwell fought a losing campaign to preserve the Chinese supply line through Burma, the famous Burma Road (q.v.). Thereafter he urged China to revitalize its army and break the Japanese blockade by retaking Burma, but the Chinese preferred to stress U.S. air power. The Japanese overran U.S. air bases in east China in 1944, as Stilwell was advancing deeply into Burma. The U.S. then proposed that Stilwell be placed in command of all Chinese forces, but Chiang Kai-shek and the Chinese central government, fearing he might upset the domestic balance of power, forced his recall.

At his death, which took place at San Francisco, Calif., on Oct. 12, 1946, Stilwell commanded the 6th Army. *The Stilwell Papers* were published in 1948.

**BIBLIOGRAPHY.**—C. L. Chennault, *Way of a Fighter* (1949); C. F. Romanus and R. Sunderland, *Stilwell's Mission to China* (1953) and *Stilwell's Command Problems* (1956). (R. Sn.)

**STIMSON, HENRY LEWIS** (1867–1950), U.S. lawyer and statesman who served as secretary of state in the early 1930s and as secretary of war throughout World War II. He was born in New York City on Sept. 21, 1867, the son of a successful and socially prominent banker and physician. He was educated at Phillips Academy (Andover, Mass.), Yale University (A.B., 1888), Harvard University (A.M., 1889), and Harvard Law School. Admitted to the New York bar in 1891, he joined the law firm of Elihu Root two years later.

From 1906 to 1909 he was U.S. attorney for the southern district of New York State; he distinguished himself especially for his devotion to the "trust-busting" policies of his friend and mentor, Pres. Theodore Roosevelt. At Roosevelt's request, he ran in 1910 as the Republican candidate for governor of New York, but was defeated. From 1911 to 1913 he was secretary of war in the cabinet of Pres. William Howard Taft. During World War I he served briefly as colonel of the 31st field artillery in France, and after the war he opposed Pres. Woodrow Wilson's plans for U.S. membership in the League of Nations. Stimson prospered as a lawyer during the 1920s, made some shrewd investments, and became, as he said, a "rich man." After 1927 his firm bore the name Winthrop, Stimson, Putnam & Roberts.

In 1927 he was recalled to public life by Pres. Calvin Coolidge who sent him as a special commissioner to Nicaragua to mediate between Pres. Adolfo Díaz and the rebel leader José María Moncada. He arranged an armistice on the understanding that the United States should supervise the election of 1928. Appointed governor general of the Philippine Islands in December 1927, he opposed the Philippine independence movement and pursued a program of economic development of the islands with a view to converting them into "self-governing possessions or colonies whose citizens did not participate in our citizenship."

From 1929 to 1933 Stimson served as secretary of state in Pres. Herbert Hoover's cabinet. He led the U.S. delegation to the London Naval Conference in 1930. When, in 1931, the Japanese began military operations in Manchuria, he resisted efforts of the Chinese government and the League of Nations to obtain U.S. support against Japan. As the Japanese proceeded to overrun Manchuria, however, he took a stronger and stronger stand against Japanese aggression. He sent to Japan and China identical notes (Jan. 7, 1932) stating that the U.S. did not intend to recognize as legally valid any situation, treaty, or agreement impairing the treaty rights of the United States or brought about by means contrary to the Pact of Paris. This nonrecognition policy afterward became known as the Stimson doctrine. In January 1933 he took part in conferences on the international situation with President Hoover and President-Elect Roosevelt, and advocated close cooperation between the United States and the League in censuring and punishing Japan. Later, as an elder statesman, he urged cooperative international action against Italian and German as well as Japanese aggressions.

In 1940 Stimson, though a lifelong Republican, was appointed secretary of war by Pres. Franklin D. Roosevelt, who at the same time appointed another prominent Republican, Franklin Knox, as secretary of the navy. As secretary of war, Stimson guided the expansion and training of the U.S. Army throughout World War II. He also acted as President Roosevelt's and later as Pres. Harry S. Truman's chief adviser on atomic policy. To President Truman he recommended that atom bombs be dropped on Japanese cities that had military importance, and he afterward justified the bombing of Hiroshima and Nagasaki on humanitarian grounds. He wrote that use of the bomb accelerated the surrender of Japan and thus saved many more lives than it cost. He left office in September 1945 and died Oct. 20, 1950, in Huntington, N.Y.

In 1948 Stimson, aided by McGeorge Bundy, published an autobiographical work entitled *On Active Service in Peace and War*. Earlier books by Stimson appeared as follows: *American Policy in Nicaragua* (1927), *The United States and Other American Republics* (1931), *Pact of Paris* (1932), and *Far Eastern Crisis* (1936). (R. N. Ct.)

**STIPPLE AND CRAYON ENGRAVING**, two closely related print-making processes that once enjoyed great popularity but became almost obsolete with the advent of lithography in the 19th century. The aim of stipple engraving was to produce tone by a number of dots or flicks, whereas that of crayon engraving was to render the lines of a chalk drawing rather than tonal surfaces. Both were produced on copperplates. In stipple engraving the plate was covered with the usual etching ground, and the outlines and principal shadows were indicated by dotting this ground with the etching needle or a small-toothed wheel called the roulette. The plate was then bitten with acid and the ground removed. The composition was finished by dotting or stippling with the point of the stipple-graver, an instrument especially curved for this purpose. There is a great variety of roulettes, and those used in crayon engraving are made to reproduce the texture of chalk and pencil. With this method, as in stipple engraving, the ground is removed and further elaboration and completion are accomplished by working directly on the plate. Impressions are obtained in both media by putting the plates through a press. The ancestor of these two processes was the "dotted manner" (*manière criblée*) of the 15th century and the dotted indication of lines and shadows found in the engravings of Giulio Campagnola (c. 1482–c. 1514), Ottavio Leoni (c. 1576–c. 1628) and Marcello Fogolino (active c. 1520–40), but these effects were produced by short flicks of the engraver's burin and did not involve biting the plate with acid. Similar to this was the dotted work employed by goldsmith engravers in Germany and the Netherlands at the end of the 16th and the beginning of the 17th century.

In the 18th century when the crayon and pastel drawings of François Boucher and others were popular in France, the aim of engravers was to reproduce their texture by means of the copperplate. The invention of crayon engraving was claimed separately by Jean Charles François, Gilles Demarteau, who used his own version of it with artistic feeling, and Louis Marin Bonnet. It seems François was the first to work with this method although Bonnet is credited with what is known as the "pastel" manner, a method of printing a crayon engraving in various colours from several plates and using a separate plate for each colour. François taught the process of crayon engraving and the application of colour in printing to William Wynn Ryland (1732–1783), a young English line engraver who had been studying in Paris and who, when funds were lacking after his return to London, bethought him of the new manner of engraving he had learned. Ryland collaborated with Francesco Bartolozzi (1727–1815) and together they modified and developed it as stipple engraving.

The new method proved to be easy, simple and rapid. The outline was etched in a series of dots, and all the shadows were put in with larger or closer dots or tiny groups of dots. When all the biting was over the ground was removed and the finishing was done with drypoint and the stipple-graver. Then the printing was done with black, red or several coloured inks. A rag stump, or *poupée*, was used and the plate freshly cleaned for each impression. Beginning by translating the pseudoclassical designs of

Angelica Kauffmann and Cipriani, which had acquired much popularity, Ryland and Bartolozzi found the new method exceedingly profitable. To the ready hand of Bartolozzi it came as a charming gift, with the facilities of the medium linking themselves to his caressing sense of beauty. All the painters of the day were anxious to share in the profits so readily made by the stipple prints, and few native engravers could resist the attraction of the new method. It also brought Italian and French engravers to learn it and work for the English market. There was, up to the war with revolutionary France in 1793, a great trade in English prints on the continent, and Bonnet and other French engravers by adopting the stipple method tried to get a share in this trade by issuing prints with titles in English, often misspelled. The line engraver, Sir Robert Strange, launched an indignant attack against stipple and even denied its claims as engraving at all, though there was no denying its efficacy as a medium for colour-printing. The white of the paper showing beneath the tinted dots afforded a peculiarly luminous quality and thus gave it a superiority over the coloured mezzotint. The popularity of stipple continued as long as the special subjects for which it was used remained in fashion. It waned with the advent of colour lithography and is no longer practised.

**STIRLING**, a midland county of Scotland, stretches from Loch Lomond in the west to the Firth of Forth in the east; the River Forth forms part of its northern border with the county of Perth, while the counties of Lanark and Dunbarton lie south and west. Area 451 sq.mi. (1,167 sq.km.).

**Physical Geography.**—The Highland boundary fault, running northeastward from near the southern end of Loch Lomond, limits the northwestern Highland prong of the county; there Dalradian schists form a bleak moorland ridge over 3,000 ft. (915 m.) high in parts (Ben Lomond 3,192 ft. [973 m.]), sloping to oak woods on the lake shores. Southeast of the fault, conglomerates of Lower Old Red Sandstone age, lapped unconformably by Upper Old Red Sandstones, form a depression which is a westerly continuation of Strathmore, Perth, interrupted by a low ridge which forms a Forth-Clyde watershed; Flanders Moss borders this zone along the Forth. Towering over this lowland, with abrupt drops of 1,000 ft. (305 m.) in places, are the intrusive volcanic porphyries of Carboniferous age comprising the Campsie Fells, the Fintry and Kilsyth hills, and filling the centre of the county; the successive lava flows are clearly seen. The Carron flowing to the Forth and the Endrick flowing to Loch Lomond subdivide the plateau with its rolling surfaces between 1,500 and 2,000 ft. (Earl's Seat 1,896 ft. [578 m.]), probably remnants of a once-continuous surface between the Highlands and Southern Uplands. Nardus moorland grazed by blackface sheep alternates with patches of peat bog. The county contains small portions of the Ochil Hills in the northeast and the Kilpatrick Hills in the southwest, both similar volcanic intrusions and separated from the Campsies by the Forth Valley and the Strathblane lowland respectively. These lowlands are linked by the narrow corridor which skirts the steep southern face of the central hills. This is Scotland's waist, used by all the major communication lines between the Forth and the Clyde. To the southeast lies part of the great syncline containing the productive coal measures of the Central Coalfield, rising to a bleak upland about 500 ft. (152 m.) round Slamannan. Ice moving south, then east, plastered the lowlands with boulder clay; at 50 ft. and 100 ft., raised beaches flank the alluvial flats bordering the meandering Forth.

The principal lochs include the greater part of the eastern waters of Loch Lomond, a small portion of the northern end of Loch Katrine, and Loch Arklet, in the northwestern area, which, with Loch Katrine, provides the water supply of Glasgow. The Carron Reservoir in the Denny Hills provides the water supply to the greater part of the county. The Forth and Clyde Canal crosses the southeastern corner of the county from Grangemouth

to Castlecary. Rainfall decreases from 100 in. (2,540 mm.) in the northwest highland to 30 in. (760 mm.) along the Forth; conditions are milder and wetter toward the west. (A. M. LE.)

**History.**—The Antonine Wall, built by Lollius Urbicus in A.D. 142 and connecting the Forth and Clyde, passes through the south-east of the county, in which it is locally known as Graham's Dyke. At Castlecary (where the Romans used coal in the fort) and Camelon many relics have been found. The Camelon Causeway ran northward to Stirling and the Forth, where there was a station near the present bridge of Drip. Then it crossed the river to Ardoch (Braco) in Perth. After the withdrawal of the Romans the native Picts gradually retired before the advance of the Saxons and Scots. By the time of Malcolm Canmore (d. 1093) the lowland area had become settled. Stirling, which received a royal charter from David I (c. 1130), became a trading centre. King James VI made Airth (1597) and Falkirk (1600) burghs of barony. The Stuart kings ruled from Stirling Castle until the union of the crowns. The county played a conspicuous part in the struggle for Scottish independence, being particularly associated with many of the exploits of Sir William Wallace and Robert I, the Bruce. The three great battles of the independence were fought in the county—Stirling Bridge (1297), Falkirk (1298), and Bannockburn (1314). James III was stabbed to death in a cottage in the village of Milton after the Battle of Sauchieburn (1488), but apart from the disastrous defeat of the Covenanters at Kilsyth (1645) and the transitory triumph which Prince Charles Edward won at Falkirk (1746), the history of the county practically centres in that of the county town. (See STIRLING [burgh].)

**Population and Administration.**—The population in 1961 of the administrative county was 194,876; 582 people spoke Gaelic as well as English. Falkirk (pop. 1961, 38,044) and Stirling (the county town and only royal burgh, 27,551) are large burghs, the small burghs being Grangemouth (18,857), Kilsyth (9,831), Denny and Dunipace (7,760), and Bridge of Allan (3,315).

The county, with the county of Clackmannan, sends three members to Parliament. It forms a sheriffdom with the counties of Dunbarton and Clackmannan; there are resident sheriff substitutes at Stirling and Falkirk.

**The Economy.**—Because of varying rainfall and different soils, Stirling has two types of agriculture. In the west, farms are largely used for dairying and feeding store cattle. In the east and northeast, and particularly on the (alluvial) Carse, a system of arable and stock feeding is practised. Wheat and beans grow well but the outstanding crop is timothy grass, which gives heavy yields as hay or produces seed of very good quality.

Hardy sheep are grazed on the hills. Stirling is the market centre for a wide area and has sales of lambs, sheep, and cattle.

Birches and conifers grow on the lower slopes of the mountains in Buchanan and Drymen, and oaks on the banks of Loch Lomond.

The coalfield of the southeast has been worked out and coal is chiefly produced in the central area at Fallin and Manor Powis. Firebricks are manufactured in large quantities at Bonnybridge and Whitcross, and there are ironworks at Carron, Falkirk (q.v.), Bonnybridge, Denny, and Larbert (q.v.).

Nails are made at Lennoxton; carpets are manufactured at Bannockburn (q.v.); Grangemouth (q.v.) with a shipyard is the second port in Scotland and is one of the biggest centres for dyes and pharmaceuticals and has a modern oil refinery with an associated chemical industry producing plastics and synthetic rubber. Tanning, papermaking, brewing, and distilling are carried on at different places, and there is an aluminum mill in Falkirk.

See A. G. Ogilvie (ed.), *Central Scotland in Great Britain, Essays in Regional Geography* (1928); Land Utilization Survey of Britain, *Land of Britain*, pt. 21–23, *Lanarkshire, Dunbartonshire and Stirling-shire*, by L. D. Stamp (1946).

**STIRLING**, a royal, large, and parliamentary burgh, river port, and the county town of Stirling, Scot., on the right bank of the Forth, is 37 mi. (59.5 km.) NNW of Edinburgh and 27 mi. (43 km.) NNE of Glasgow by road. Pop. (1961) 27,551. The old town and castle occupy the slopes of a dolerite hill (420 ft. [128 m.] above the sea) terminating on the north and west in a

precipice. The modern town was laid out on the level ground at the base, especially toward the south. Remains of a town wall exist at the southern end of the Back Walk. Formerly there were two main entrances—the South port and the “auld brig” over the Forth to the north, a high-pitched structure of four arches now used only by pedestrians. It dates from the end of the 14th century and was once literally “the key to the Highlands.” Just below it is the bridge completed in 1831 from designs by Robert Stevenson, and below this again the railway viaduct. The castle crowning the hill is of unknown age, but from the time of Alexander I (d. 1124) until the union of the Scottish and English crowns in 1603, it was intimately associated with the fortunes of the Scottish monarchs. It is approached from the esplanade, on which stands a colossal statue of Robert Bruce. The main gateway, probably built by James III, gives access to the lower and then to the upper square, on the south side of which stands the palace, begun by James V (1540) and completed by his widow, Mary of Lorraine. The east side of the quadrangle is occupied by the Parliament House, a Gothic building of the time of James III, used as a barrack room and stores. On the north side of the square is the Chapel Royal, founded by Alexander I, rebuilt in the 15th century and again in 1594 by James VI (who was christened in it), and afterward converted into an armoury and finally a store-room. The former banquet hall contains the regimental museum of the Argyll and Sutherland Highlanders. In the plain to the southwest were the King's gardens, now under grass, with an octagonal turf-covered mound called the King's Knott in the centre. Farther south lies the King's Park. On a hill of lower elevation than the castle and separated from the esplanade by a depression styled the Valley—the tilting ground of former times—a cemetery has been laid out where are the Virgin Martyrs' Memorial (in memory of Margaret MacLachlan and Agnes Wilson, who were drowned by the rising tide in Wigtown Bay for their fidelity to the Covenant [1685]), a large pyramid to the memory of the Covenanters, and the Ladies' rock, from which ladies viewed the jousts in the Valley.

Adjoining the cemetery on the south is the Church of the Holy Rude (Rood), portions of which may have formed part of the original church founded by David I. Following the Reformation it was partitioned into two churches, but was restored to its original condition in 1936–40. The choir (the old East Church) was added in 1494 by James IV, and the apse a few years later. At the west end is a battlemented square tower. The nave (the former West Church) is a transition between Romanesque and Gothic, with pointed windows. The main entrance to both churches was by the south transept, with its crow-stepped Gothic gable. The choir is in the Decorated and Perpendicular styles. Within its walls Mary Stuart, queen of Scots, was crowned in 1543, when nine months old; on July 29, 1567, James VI (then 12 months old) was crowned, John Knox preaching the sermon. James Guthrie (d. 1661), the martyr, and Ebenezer Erskine (1680–1754), founder of the Scottish Secession Church, were two of the most distinguished ministers. To the southwest of the church is Cowane's Hospital, founded in 1639 by John Cowane, dean of guild, and now used as a guildhall. Near the principal entrance to the esplanade stands Argyll's Lodging, the earlier part of which was erected about 1630 by William Alexander, 1st earl of Stirling, the founder of Nova Scotia. On his death in 1640 it passed to the 1st marquess of Argyll and later was made into a military hospital. It is a fine example of a baronial town house. Broad Street contains Mar's Work, the unfinished palace begun by John Erskine, 1st earl of Mar, about 1570, according to tradition, out of the stones of Cambuskenneth Abbey; the old town house, erected in 1701 to replace that in which John Hamilton, the last Roman Catholic archbishop of St. Andrews, was hanged in 1571 for alleged complicity in the murders of Lord Darnley and the regent Moray; the town cross, restored in 1891; and the house which was, as a mural tablet says, the “nursery of James VI and his son Prince Henry.” The Smith Art Gallery and Museum in Dumbarton Road was founded in 1873 by Thomas Stewart Smith, an artist.

The Abbey Craig, across the Forth, an outlying spur of the Ochils, 1½ mi. NE of Stirling, is a thickly wooded hill on the top

of which stands the National Wallace Monument (1869), a baronial tower, 220 ft. high, with a "Hall of Heroes" containing busts of eminent Scotsmen. Cambuskenneth Abbey, on the left bank of the Forth, about 1 mi. ENE of Stirling, was founded by David I in 1147 for Augustinian monks. Several Scots parliaments met within its walls. At the Reformation Mary Stuart bestowed it (1562) on the 1st earl of Mar, who is said to have used the stones for his palace in Stirling. All that remains of the abbey is the massive, four-storied tower, the west doorway and the foundations of some of the walls. The remains of James III and his queen, Margaret of Denmark, who were buried within the precincts, were discovered in 1864 and reinterred the next year under a tomb at the high altar at the expense of Queen Victoria.

Stirling was also known as Snowdown, which became the official title of the Scots heralds. The Romans probably had a station there. The hill was in Pictish territory until their kingdom was merged with Dalriada after 843. Under Alexander I it became a royal burgh and later was one of the Court of Four Burghs (first mentioned in 1292 and lasting till the early 16th century). In 1174 it was promised to the English in security for the Treaty of Falaise, but was never exacted by Henry II. The earliest known charter existed c. 1130 and a later one was granted in 1226 by Alexander II who made the castle a royal residence. The fortress was repeatedly besieged during the wars of Scottish Independence and fell to the English in 1296. Recovered after the Battle of Stirling Bridge (September 1297), it fell again, with the town, to Edward I in 1304. The English held it for ten years, and it was in order to raise the Scottish siege in 1314 that Edward II risked the Battle at Bannockburn, 2½ mi. S. Edward Balliol surrendered it in 1334 in terms of his compact with Edward III, but the Scots regained it in 1339. From that time until the collapse of Queen Mary's fortunes after the Battle of Langside in 1568, Stirling almost shared with Edinburgh the rank and privileges of capital of the kingdom. It was the birthplace of James III. In 1571 an attempt was made to surprise the castle by Mary's adherents, the regent Lennox being slain in the fray, and seven years later it was captured by James Douglas, 4th earl of Morton. It was occupied in 1584 by the earls of Angus and Mar, the Protestant leaders, who, however, fled to England on the approach of the king. The next year they returned with a strong force and compelled James VI to open the gates, his personal safety having been guaranteed.

After the union of the crowns (1603) Stirling ceased to play a prominent part on the national stage. The Privy Council and Court of Session met in the town in 1637 because of the disturbed state of Edinburgh. In 1641 Charles I gave it its last governing charter, and four years later Parliament was held in Stirling because of the plague in the capital, but the outbreak of the pest in Stirling caused the legislators to move to Perth. During the Civil War the Covenanters held the town, to which the committees of church and state adjourned after Oliver Cromwell's victory at Dunbar (1650), but in August of the next year the castle was taken by General George Monck. In 1715 the 3rd duke of Argyll held it to prevent the passage of the Forth by the Jacobites, and in 1746 it was ineffectually besieged by Prince Charles Edward.

Stirling, with Falkirk and Grangemouth, returns one member to Parliament.

The most important industries are associated with agriculture: agricultural engineering; the production of farm and garden seeds and fertilizers; livestock marketing; sawmilling; bacon curing; and sausage making. Rubber, asbestos and fibre insulating materials are made; other industries include the manufacture of cigarettes, concrete, and carpets. Coal mining employs many of the inhabitants. There is some shipping from the small harbour which is accessible only at high water.

**STOA**, in Greek architecture, a long open building with the roof supported by one or more rows of columns parallel to the back wall. A row of rooms may open from the rear of the colonnade; a second story is often added. Stoa surrounded the market places and later the sanctuaries and served for nearly all public and private business, commercial and legal, as well as for public promenade. Athens, Corinth, Delos, and the Asia Minor cities offer good examples.

(L. T. SÆ.)

**STOAT**, a common name for the small northern weasel *Mustela erminea*, especially when it displays its summer pelage of brown upper parts and whitish under parts. These slender, agile, bloodthirsty mammals measure 7½ to 13½ in., approximately 40%

JOHN MARKHAM  
STOAT, OR ERMINE (*MUSTELA ER-  
MINEA*), IN BROWN SUMMER COAT

of which is tail. In colder climates the winter coat is white, except for the black tail-tip; the animal in this colour phase is popularly called ermine, as are other winter-white weasels. In moderately cold climates the fur becomes only partially white. (The colour change is the result of molting and is an inherited hormonal response to the daily amount of light.)

Stoats occur from the Arctic southward in eastern America to Pennsylvania and in the west to northern New Mexico. They also extend from the British Isles to Japan and as far south as Algeria. They are versatile as to habitat but are most abundant in thickets and woodland, and in damp, grassy, semi-timbered areas. Females are smaller than males and northern races smaller than southern. Their diet consists of small mammals, birds, eggs, frogs, and occasional invertebrates. The prey is seized usually at the base of the skull, the sharp teeth penetrating the brain. Larger prey is seized by the throat and held with fierce tenacity. Stoats are preyed upon by larger carnivores and birds of prey. Mating takes place in late spring or early summer with gestation prolonged as much as 10 months because of delayed implantation of the egg. The 4 to 13 blind young are born in a burrow. They reach old age in 7 to 8 years.

The winter-taken pelts, prized for fineness and pure colour, are among the most valuable of commercial furs and are obtained mainly in northern Eurasia.

(K. R. KN.)

**STOCK**, a plant of the mustard family (Cruciferae), native to the Mediterranean area but widely grown in many horticultural varieties for its showy, fragrant flowers. It is *Matthiola incana*, a usually branched annual, biennial, or perennial that grows to three feet tall and has narrow, hairy leaves up to eight inches long. The flowers—white, blue, pink, purple, or yellowish—have four petals (more in double varieties). The fruit is a pod containing many flattened, winged seeds. Double stocks do not produce seeds. The night-scented stock, *Matthiola bicornis*, also native to the Mediterranean area, has purplish, night-blooming flowers and two-horned pods.

Stocks are easily raised from seeds and do well in ordinary soil. The two main groups are summer stocks (variety *annua*) and winter stocks. Summer stocks, or ten-weeks stocks, flower 7 to 14 weeks after sowing, which is usually done outdoors in April or under glass in March. Winter stocks, usually sown in June or July, bloom the following year, although some varieties will flower in autumn of the same year if sown early enough.

(J. W. Tr.)

**STOCK** (SHARES). The money invested by individuals in business corporations is divided into units called stock in the United States or shares in Great Britain. Such stock represents a permanent investment in the business. The investor receives a certificate as evidence of his ownership of a part of the corporation. The detailed contractual relationship between the corporation and its stockholders sets forth the division of the risk, income and control of the business. Stockholders have the right to share in the management of the corporation, to share proportionately in any dividends declared and in the assets of the business in case of liquidation, and to approve or disapprove proposed changes in the original contract. The stock certificate itself, which has been called both a negotiable and quasi-negotiable instrument, may be transferred from person to person. In Great Britain the discussion of the rights of shareholders is relatively simple because

the Companies acts apply to the entire nation. In contrast, there are great diversities in the rights of stockholders in the United States because each state has its own corporation law.

By the middle of the 20th century virtually all large privately owned businesses and a large proportion of smaller businesses in the United States and Great Britain were organized as corporations and had issues of stock outstanding. The fact that the ownership of both large and small corporations is divided into shares makes any simple description of classes of stock and the rights of stockholders necessarily vague. Only by unreasonably stretching the legal fabric can the shares of the very large and very small businesses be included under the same cloak.

The Companies acts in Great Britain, the Securities act (1933) and Securities Exchange act (1934) of the United States, and the corporation laws of the individual states have tended to give more publicity to corporate affairs for the protection of the shareholders of public companies. The rights of minority interests are also protected by law. The rights of the shareholders of private or closely held corporations may be quite different from those of public companies. The right of the shareholder to transfer his shares is often restricted by agreement among the shareholders. Profits may be divided on the basis of private agreements. Shareholders' rights may become indistinguishable from those of partners. In the United States even one-man corporations are not uncommon. By the 1960s the laws governing the establishment of corporations in the United States and the rights of stockholders were beginning to recognize the differences between the problems of small businesses organized as corporations and large publicly owned businesses.

**Dividends.**—One of the basic rights of stockholders is to share in the profits of the corporation. These profits may be paid out to the investors in the form of cash dividends or retained in the business to help finance its growth. Stockholders have no right to receive dividends until they are declared by the board of directors. Dividends are usually declared as a certain amount per share by class of stockholder.

Cash dividends, with the exception of liquidating dividends, generally cannot be legally authorized if the effect of such a dividend payment would be to reduce the owners' equity in the business below their original contribution. However, such a limitation is of little importance to large corporations that have grown partly or wholly by "plowing profits back into the business." It is usually recognized that profits retained in the business in fact, if not legally, become a part of the permanent investment of the shareholders. Cash dividends generally cannot be paid if the corporation is insolvent or if the payment of the dividend would result in insolvency.

Dividends are sometimes paid in the form of additional common stock of the corporation rather than in cash. Such stock dividends, as they are called, give recognition to the fact that the profits retained in the business represent a permanent investment. Many rapidly growing, publicly held corporations have a policy of paying dividends partly in stock as well as in cash, thus conserving the firm's cash so that it may be used to help finance expansion. The stockholder may, if he wishes, sell the stock received as dividends.

Small, closely held, rapidly expanding businesses usually pay little if any dividends until such time as they prepare for their first public issue of stock. At that time the retained earnings are transferred to the common stock account and the number of shares is increased or split so that the market price of the new shares will be in the popular trading range when they are sold. Stock splits of more than 1,000-1 are not uncommon in these circumstances. In one unusual case, the shares of Biophysical Electronics, Inc. were split 62,500-1 when the firm sold common stock to the public for the first time in 1959.

The decision of a corporation to raise funds or finance by the use of equity shares rather than by borrowing is extremely complex. Some of the factors that influence the decision are: size and rate of growth of the business, distribution of shares of the business (whether closely held or publicly held), maintenance of voting control, stability of earnings, personal and corporate income

tax rates, desire to avoid fixed contractual obligations for the payment of interest and principal on a debt, and availability and relative cost of debt and equity funds. See also STOCK EXCHANGE.

(R. M. S.)

## UNITED STATES

As noted above, a share of stock is an ownership interest in a corporation. Each stockholder or shareholder has the fractional interest in the corporation that may be measured by comparing the number of shares he holds with the total number of the corporation's shares outstanding. This interest includes the right to share in the control of the organization's activities, to share in dividends as declared, to purchase additional shares when and if issued and to share in assets remaining after paying creditors upon termination of the corporation's existence. One or more of these rights, however, may be withheld or qualified by particular state laws or by the articles of incorporation.

As compared with partners in an unincorporated business, corporation stockholders have the advantage of limited liability but their freedom to withdraw assets from the firm is restricted. The restriction on owners' withdrawals creates the concept of "stated capital"—the portion of owners' interests which must not be withdrawn. The initial investments of stockholders usually exceed the amount designated in the articles of incorporation as stated capital. The legal term for this excess is "paid-in surplus" or "capital surplus." Profits accumulated as the corporation carries on its functions add to the owners' interests, while dividends paid by the corporation reduce the owners' interests in the corporate fund of assets as these assets are transferred to them. The excess of accumulated profits over dividends declared is called retained earnings or earned surplus. Thus, the owners' interests in corporate assets commonly arise from two sources—original investments and retained earnings—but the legal concept of stated capital requires a distinction between any part of the owners' original contributions that may be returned to them and the part that must be preserved.

Dividends and a rise in the price of the shares are the basic incentives for investing in an incorporated business by purchasing its stock. The payment of dividends entails the transfer of assets from the corporation to its stockholders, thus reducing both the total assets of the corporation and the owners' interests therein. The legal category of owners' interests that are reduced by dividends is partly regulated by law and partly at the discretion of the corporation's board of directors who have the responsibility for declaring dividends. Unless the corporation has covenanted with a specific group of creditors to restrict its dividends in some manner, the directors normally have the power to declare dividends which reduce retained earnings. Paid-in surplus is, in most states, available for reduction by dividends under certain circumstances. Stated capital, however, may not be reduced by dividends, although some states permit dividends not in excess of profits earned in the most recent fiscal period even if the stated capital of the corporation has been impaired by earlier losses. In such a case the earned surplus is negative and the total of the owners' interests is less than stated capital.

**Classes of Stock.**—Many corporations have only one class of stock, frequently referred to as capital stock or common stock in the United States or ordinary shares in Great Britain. Each share has full voting and dividend rights as well as the right to share in assets upon dissolution. The pre-emptive right to buy new issues of the corporation's stock is provided by law in some U.S. states or by articles of incorporation in others. The existence of two classes of stock means that one or more of these fundamental rights does not attach equally to the shares of all classes.

**Voting and Nonvoting Shares.**—Shares whose holders may not vote at all or may not vote on certain issues, such as the election of directors, may be referred to as nonvoting shares. The two classes are often officially designated as class A and class B shares.

**Preferred Stock.**—To appeal to investors who wish to be sure of receiving dividends regularly, many corporations issue a class of stock that gives its holders a preferential claim to dividends. The most common provision of this type is that no dividends may be

declared on the common stock unless dividends of a stipulated amount per year have been declared on the preferred shares. Usually this preferred dividend is cumulative, meaning that any dividend omitted is added to future dividends payable on the preferred shares before the common shares may receive a dividend. Noncumulative preferred shares have a weak position legally because the board of directors is under no obligation to declare dividends on any class of stock even if earnings are ample.

Another type of preference that may be granted relates to the distribution of assets upon dissolution of the corporation. The articles of incorporation may provide that one class of stock shall rank before another class when assets are distributed at the end of the corporation's life. The amount of this preference must be specified; it may vary depending upon whether the liquidation is voluntary or involuntary.

**Convertible Preferred Stock.**—The major disadvantage of preferred stock is that the holder does not share in exceptionally good fortunes of the issuing corporation, because preferred shares rarely receive dividends in excess of the preferential rate. This shortcoming can be remedied by giving stockholders the right to exchange preferred shares for common shares in a stated ratio so that conversion may become attractive if the market price of the common stock increases by a modest percentage. For example, when the common shares are selling at \$21, preferred shares convertible at the rate of four common for one preferred share may be issued at \$100. If the company prospers and the price of the common shares rises to \$30, the preferred stockholder may share in the prosperity by converting a share of preferred into four shares of common with an aggregate value of \$120. Under such circumstances the market price of the preferred stock will also rise.

**Stock Values.**—Articles of incorporation must specify the maximum number of shares of stock to be issued by a corporation. The total stated capital to be attributed to this number of shares may also be set, in which case the total stated capital divided by the number of shares determines the par value of each share. Alternatively, the incorporators may exclude from the articles any reference to a maximum stated capital or par value per share, instead designating the shares as no-par shares. In such cases, either the stockholders as a group or the board of directors is charged with the responsibility for declaring what portion, if any, of the proceeds from the issuance of the shares is to be designated as paid-in surplus. Thus, no-par shares outstanding are said to have a stated value per share equal to the increase in stated capital recorded upon their issue divided by the number of such shares issued. The significance of the par or stated value of a share of stock is tied to the concept of stated capital and the dividend limitations connected therewith; par or stated value is unlikely to be related to the stock's market value.

The "book value" of a share of stock is the shareholder's equity in the corporation as indicated by the balance sheet. If only one class of stock is outstanding, the entire net worth—including stated capital, paid-in surplus and retained earnings—divided by the number of shares outstanding, is the book value per share. If both preferred and common shares are outstanding, the total liquidation preference of the preferred shares is subtracted from net worth before computing the book value of the common shares.

Shares of stock are assignable personal property and are frequently bought and sold in the stock market. The market value of a share subsequent to its issue date may be substantially different from its book value. The general reason for the purchase of stock is to obtain cash receipts in the future in excess of the purchase price. The anticipated receipts either take the form of dividends or occur upon resale to another party who purchases it to obtain dividends. The corporation's capacity to pay dividends over a long period is affected by factors other than the capital funds it employs; hence the market value of shares may be higher or lower than their book value.

**Changes in Capital Structure.**—Stock dividends can be declared by the board of directors if sufficient authorized but unissued shares are available. A 5% stock dividend involves the issuance for no consideration of one share for each 20 shares held. The net worth of the corporation is not changed by this step, which

is sometimes characterized as dividing the pie into more pieces. Unlike a cash dividend, a stock dividend paid to a holder of common shares is not considered income. The stated capital of the corporation is increased by a transfer from retained earnings or paid-in surplus.

A stock split is similar to a stock dividend in that the net worth is unchanged but the number of shares is increased. However, stated capital is not increased by a stock split. An example is the splitting of 1,000,000 shares of \$10 par value into 2,000,000 shares of \$5 par value. Occasionally the number of shares is reduced and the stated capital relating to each increased by a reverse stock split.

When a corporation whose stockholders enjoy the pre-emptive right wishes to raise capital funds through the issue of additional stock it first offers the stock to its shareholders in proportion to their holdings. Thus, if the new shares will increase the number of shares outstanding by 20%, a stockholder who owns 100 shares is entitled to purchase 20 shares. In order to assure the success of the rights offering, the subscription price on the new shares is usually set below the current market price. Accordingly, the right to purchase the new shares is valuable in itself, and these rights are frequently bought and sold.

Treasury shares are shares acquired by their issuer and held pending reissue or retirement. The acquisition by a corporation of its own shares is strictly regulated by law in order to prevent the circumvention of the stated capital restriction by returning assets to owners through the purchase of their shares to the detriment of creditors.

## GREAT BRITAIN AND THE COMMONWEALTH

**Great Britain.**—In Great Britain the fundamental difference between stock and shares is a technical one only, though the two words have acquired overtones of meaning which tend to differentiate them in general usage. Since 1862, the term "stock" has signified a subscribed fund resolvable into parts as small as pounds, shillings and pence for use as corporate capital or a loan. Stock is therefore divisible and transferable in any amount desired not lower than a fraction specified by practical considerations. The term "share" on the other hand is used when the subdivision of the capital is of uniform amount. Thus a holding of stock is described as "£100 stock" or "£100 worth of stock," while a holding of shares is called "100 £1 shares." Furthermore, stock may be bought or transferred in odd amounts, e.g., £10 8s. 5d. stock, whereas shares must always be subscribed or exchanged in multiples of the specified face value, be it £1, 10s., 5s. or even 1s. Thus a sale of fractions of a share is not permitted.

Dividends payable on British shares are always expressed in one of two forms: "a dividend of 6d. (or so much) per share" or "a dividend of five (or so much) per cent," the latter meaning a dividend equivalent to the named percentage on the face value of each share. If the shares are £1 shares, 5% is equivalent to 1s. per share, but if they are 10s. shares, it is equivalent to 6d. per share. Dividends are normally paid annually or twice-yearly, those in the latter case being called interim and final payments.

The market price of stock or shares, which is related to the dividend payments, is normally expressed either in shillings and pence (e.g., 11s. 6d. or 27s. 4½d.) or in pounds and fractions of pounds (e.g., 13¼, meaning £13 5s. 0d., or, in the case of stock, 87½, meaning £87 12s. 6d. per £100 stock).

In addition to the annual return the price of stock and shares depends on the degree of risk attached to the holding. Stock is a term normally applied in Great Britain to a loan or debenture repayable within or at a certain specified time and repaying a fixed rate of interest until that date. Shares, however, usually represent permanent capital as opposed to loans and debentures and fall into three main categories, each of which implies a different degree of risk to shareholders. These are preference, ordinary and deferred.

Preference shares, like loans and debentures, usually receive a fixed return only, although occasionally they participate with the ordinary shares in any further profits. They are then called participating preference shares. In all cases preference shares, as

their name implies, have a prior claim to profits earned and rank ahead of ordinary and deferred shares, both as to the dividend and as to repayment of capital in the event of liquidation. Thus, if a company earns £100,000 and the preference dividend (say 5% on £2,000,000 of £1 preference shares) requires the full £100,000, then the holders of ordinary shares get nothing. If the preference shares are cumulative, any arrears of dividends on them are carried forward until a sufficient profit is earned to pay off the accumulated arrears; and this must be done before any payment is made on the ordinary shares. If preference shares are not cumulative, once a preference dividend is not paid in any one year, the shareholders have no claim in respect of that dividend on any future profits.

Ordinary shares rank after preference shares but, whereas the preference shareholder is entitled to a fixed rate of dividend only if profits are made and to the return of the nominal value of his shares only in the event of a liquidation, in both cases the ordinary shareholder receives what is left. If the company has also issued deferred shares, however, it is the ordinary shareholder who receives a fixed return only (sometimes with participating rights), while the deferred shareholder receives what is left. A company seldom issues all three classes of shares; normally two only will be issued and, if these should be the first and the third, they are frequently called preferred ordinary and deferred ordinary.

In no case are the directors of a company bound to pay a dividend, however, and in practice a company will normally pay only a portion of its earned profit in any one year, frequently putting the surplus into reserve funds or development expenditures. The profits made in any one financial year are often expressed as a percentage of the issued capital, this percentage being known as earnings.

A company increases its capital by issuing additional shares. These may be issued either free as a bonus to existing shareholders, often termed a scrip bonus issue (e.g., two shares for every three held, frequently abbreviated to "two-for-three scrip"), or at a price below their current market price as a partial bonus to shareholders. In the latter case, for example, if the market price of £1 shares already in issue is 85s., new shares may be offered at 45s., a holder of two shares being entitled to buy one new one at the lower price, or to sell his right in the market to anyone who will buy it. This type of issue is known as a rights issue and the above example would be "a one-for-two rights."

Throughout the British Commonwealth the concept of stock and shares resembles closely that current in Great Britain both in terminology and practice. The one country providing a striking exception to this is Canada, which has in many respects followed the U.S. pattern.

**Canada.**—In Canada the term "stock" frequently takes the place of the English term "share." Thus, although preference shares form part of the capital structure of Canadian companies, the ordinary shares are known collectively as "stock" and investors in that company are "stockholders" and not "shareholders." Furthermore, the terms "ordinary" and "deferred" are not normally used, the equity being known as "common" stock. This common stock is frequently "bearer" stock, as opposed to the "registered" shares common in Great Britain; i.e., ownership is vested simply in the bearer and no nominal registration of specific ownership is made in the company's books. Unlike British shares, Canadian stock does not always have a specific nominal or face value; it is frequently designated "of no par value" (commonly abbreviated to NPV). Common stock of Canadian companies may be divided into two sorts, class A and class B, the latter only carrying voting rights and the former carrying either a degree of preferential treatment with regard to dividends and liquidation, or participating rights, or sometimes both. Dividends are expressed in Canada as so many dollars (or cents) per share and not as a percentage, and are frequently issued together with trading information quarterly, not yearly or half yearly as in Great Britain. The most important Canadian stock exchanges are those of Toronto and Montreal.

**Australia and New Zealand.**—Australian and New Zealand shares bear a marked similarity to those in Great Britain, although

the deferred share is not normally found. Australian companies, however, unlike their British counterparts, sometimes issue unsecured registered notes. These fulfill the same function as a debenture stock, representing a loan repayable at or within a specified period; they are, however, issued in units not of £100 but of small denominations. Unsecured notes normally pay a fixed rate of interest but sometimes carry participating rights also. Occasionally they are convertible into ordinary shares. The leading stock exchanges of Australia are those of Melbourne and Sydney, while the main centre of share dealing in New Zealand is at Wellington. Australian shares enjoy a sizable following in the stock exchanges at Singapore and Hong Kong. Both these markets follow closely the British pattern and the former is the home market for Malayan rubber shares in which active dealings take place in London.

## OTHER COUNTRIES

Stocks and shares have formed an integral part of the economic development of almost every country in the world, both in assisting their various governments to raise the finances necessary for their administrative program and in providing the capital required by private concerns in each country. Owing to the different rates of growth in economic and industrial development, however, the degree to which comprehensive trading of stocks and shares has been centralized and developed varies widely. In this respect the stock exchanges in London and New York had, by 1900, established a predominant position both in breadth and volume of trading and this position has since been consolidated, but the following cities also have stock exchanges which have gained international recognition: Tokyo, Cairo, Amsterdam, Paris, Brussels, Milan, Geneva, Frankfurt am Main, Düsseldorf, Munich, Lisbon, Stockholm, Oslo and Vienna.

On all these exchanges dealings take place in governmental and provincial securities and other private bonds and shares of a national character and the concept of a share in each case is fundamentally the same as that in Great Britain, although there are many minor technical and terminological differences in the case of European and Asian countries. The capital structure of many European companies, as well as that of Japan, shows a marked preponderance of ordinary shares over preference shares, the latter forming a much smaller proportion of the total share capital than is customary in Great Britain. As against this, however, it is not unusual to find among companies of other countries different denominations of both ordinary and preference shares, a feature not found in Great Britain and alien to the British definition of a share. For example, Philips' Incandescent Lamp works, the Netherlands company whose shares, together with those of Unilever and Royal Dutch, had by 1958 achieved perhaps the widest international circulation of any non-British or U.S. industrial share, has issued both preference and ordinary shares in denominations of 1,000f, 100f and 50f. In certain countries, notably Belgium, it is common to find shares with no par value or nominal face value, as with Canada.

As in Great Britain, shares issued in other countries normally entitle their holders to vote in matters concerning the administration of the company, but in some European countries, particularly Switzerland and the Netherlands, comprehensive steps are frequently taken to ensure that voting control does not fall into the hands of non-nationals. This goal is achieved in spite of the fact that European companies tend to have a larger number of small shareholders than their counterparts in Great Britain and the United States.

In almost all European countries with the exception of Great Britain and Italy, shares are "bearer" shares and not "registered" shares. A "bearer" share certificate is, as its name suggests, a certificate vesting ownership simply in the bearer (as with an English pound note), whereas a registered certificate specifically designates the owner or subscriber by name and implies his specific registration by name in the books of the company. A bearer share certificate normally has dividend coupons attached to it, i.e., perforated slips entitling the bearer to his dividend on presentation at a bank. Partly because of this and partly because

of the smaller scope and less highly developed organization of many European and Asian stock exchanges, banks in Europe and Asia tend to take a bigger and closer part in investment and share dealing than they do in Great Britain or the United States.

South Africa is the home of many of the leading gold mining companies whose shares have an active following on the London stock exchange (where they are known as Kafirs). The home market for these issues, together with many other shares of a national and local character, is Johannesburg, where the concept of stock and shares is very similar to that in London. Dividends, however, are always expressed in shillings and pence per share and not as a percentage. These are normally paid twice yearly, while gold mining companies also issue quarterly reports to shareholders.

**STOCKBRIDGE**, a town of Berkshire county, Mass., U.S., on the Housatonic river, is located 116 mi. W. of Boston and 138 mi. N.E. of New York city. A summer and autumn resort and a region of historic interest, there are, within its area, the Stockbridge Bowl, a lake that provides opportunities for boating and fishing; Ice Glen (where caverns are lined with ice even in mid-summer); Monument mountain (1,750 ft.); and most of Tanglewood, the home of the Boston Symphony orchestra's summer centre and the Berkshire Symphonic festival. Also located in the town is the Riggs Centre, a clinic for psychiatric research and treatment.

In 1734 a plantation 6 mi. square was laid out for the Mohican Indians who had come from the Hudson valley when white settlements encroached upon their territory, and among whom Rev. John Sergeant had established a mission in 1734. In 1739 this Indian town was incorporated as the town of Stockbridge; Jonathan Edwards was in charge of the Indian church and school from 1750 to 1758. By 1800 nearly all the Indians had moved west.

The resident population of Stockbridge is over 2,000.

**STOCK EXCHANGE**, an auction market for the purchase and sale of securities such as shares, stocks and bonds. Stock exchanges, also known as bourses, play important roles in the economic life of all major industrial nations. Their primary function is to provide a convenient means for persons to invest money in business enterprises and to liquefy their investments at any time by selling their securities. ## I. UNITED STATES

There are three national stock exchanges in the United States: the New York Stock exchange, the American Stock exchange (formerly the New York Curb exchange) and the National Stock exchange (opened in 1962), all located in the city of New York. These exchanges account for about 90% of the total trading on organized exchanges in the United States. In addition, there are regional exchanges located in many of the large cities. Securities are also bought and sold in the over-the-counter market, which consists of brokers and investment bankers in all parts of the country who arrange their transactions by telephone or telegraph. See further **OVER-THE-COUNTER MARKET**.

### A. HISTORICAL BACKGROUND

The first informal organization of the New York Stock exchange took place in May 1792, although there had been trading in government securities some time before. A group of 24 merchants and brokers decided to charge a commission for acting as agents for other persons and to give preference to each other in the purchase and sale of securities. They operated under a buttonwood tree on Wall street except during inclement weather, when they went into a coffee shop.

From 1792 to 1817, interest in stocks and bonds rose as a result of the increase in government obligations and the growth of banks and insurance companies. During this period there was no restriction as to the time of operation or the number of brokers who could transact business. When the number of brokers became large, a group of them decided to organize formally. They adopted a simple constitution comparable to that of a small-town social club and called themselves the New York Stock and Exchange board. They agreed to accept the regular brokers as members, but each new member had to be sponsored by one of the existing members and then approved by the entire membership.

The crowded conditions in the street influenced the members to take permanent quarters inside. They rented a room at 40 Wall street for \$200 a year. New members were required to pay an initiation fee of not less than \$25, the amount varying with the location of the seat in the room. Each member was assigned a seat and the chairman called roll each day. An absence without excuse resulted in a fine. Continued absence resulted in expulsion. If a member did not attend regularly, it became uneconomical for him to hold his seat. (The use of the phrase, "seat on the exchange," stems from this time, when members were assigned particular seats when admitted. There are no seats on the present exchange, yet the term continues to denote membership.) During the day the chairman would call the name of each stock once, and any bids or offers would be heard for that stock and transactions effected. If a member called for a stock that had already been called, he was fined. The procedure was orderly and unexciting.

The American Civil War created much interest in speculation and the number of brokers interested in gaining seats increased. Since the number of members was limited, an outside group of brokers organized a separate exchange called the Open Board of Brokers. This group operated in uptown New York.

Because of the increased activity, a need arose for more adequate quarters for the New York Stock and Exchange board. Through contributions from members, the first building was erected. The construction of the building raised the problem of the transferability of memberships. Before this time, memberships were not transferable. Seats of deceased members were sold at auction and the proceeds given to charity. But since members now had an equity in the building, seats were made transferable in 1868. The price of a seat at that time reflected the equity of a member in the real estate as well as the value of the trading privileges.

With the advent of transferable memberships it was necessary to limit the number to protect each member's equity. The maximum number of seats was set at 533. In the meantime, however, competition was being felt from the younger members of the Open Board of Brokers, who operated at night as well as during the day. The older group had previously decided to close at 3 o'clock each afternoon. In 1869, the two groups consolidated to form the pres-

ent New York Stock exchange, with members of the Open Board of Brokers admitted without cost. This brought the total membership to 887. At about the same time, 173 new memberships were sold for \$1,000 each, bringing the total seats to 1,060. By 1879 the building had become inadequate and 40 new memberships were sold at current prices to pay for enlarging the building. This brought total membership to 1,100. Later admissions increased it to 1,375.

#### B. ORGANIZATION OF THE NEW YORK STOCK EXCHANGE

The New York Stock exchange is organized as a nonprofit unincorporated association. The government of the exchange is vested in a board of governors consisting of members, the chairman, the president of the exchange, and representatives of the public. The principal powers of the board are to elect officers, establish rules governing trading, impose penalties for violations of rules, supervise member firms and consider applications for listing. The board has a chairman and vice-chairman, but the chief officer of the exchange is the president. He is a paid employee of the association and must not be a member of the exchange. Subject to the approval of the board of governors, he selects officers to whom he delegates authority vested in him by the board.

The organization of the exchange was completely revised in 1938 in substantial accordance with the recommendations of the Conway committee, which had been formed for that purpose in 1937. Previously, the administrative problems were handled by the members. Since 1938, in addition to the paid president, the exchange has had several paid vice-presidents and a total payroll of about 1,800. This staff, however, continued to be subject to the direction of the board of governors and its standing committees. They may not hold memberships on the exchange. There is a department headed by an officer of the exchange for each standing committee. These departments, at the direction of their committees, perform the functions necessary to the proper administration of the exchange. Final responsibility and authority for decisions, however, rest with the committees.

**1. Admission of New Members.**—The first requirement for acquiring membership on the New York Stock exchange is to be in a position to meet the existing offering price. This price varies from time to time, depending on the amount of trading activity. In 1929, for example, a seat was sold for \$625,000; in 1942 a seat was sold for \$17,000. Once a potential member agrees to meet the offering price he must appear before a subcommittee on admissions with two members who act as his sponsors. By the time he appears before the subcommittee the secretary's office has gathered as much information about him as possible. He must have a record of honesty in business affairs, a knowledge of the functions of the exchange, financial stability and a definite purpose for acquiring membership other than for speculation on his own account. The exchange guards carefully against speculation in the price of memberships. If the application is approved by the subcommittee it is posted on the bulletin board of the exchange. If within two weeks no member submits evidence to indicate that the applicant should not be admitted, the board of governors takes final action. If the applicant borrows funds to purchase the seat, the lender must agree to subordinate his claims against the membership or proceeds of its transfer to all claims of the New York Stock exchange or any of its members.

The exchange also provides for an unlimited number of allied members. They must pledge themselves to abide by the constitution and the rules and become general partners in member firms. An allied member may not go upon the floor of the exchange unless he has permission of the board to serve as an alternate for a partner who is a regular member.

**2. Board of Arbitration.**—To handle disputes that arise between members, between members and allied members, and between members and nonmembers, the board of governors appoints a board of arbitration. In disputes involving nonmembers, the board of arbitration may be composed of some members who do not own seats on the exchange. There is a panel of about 100 members and 100 nonmembers who may be drawn upon to serve as arbitrators in disputes. The secretary's office handles the tech-

nical aspects of the dispute. Certain procedures are followed in filing the complaint, selecting arbitrators, covering costs of arbitration, and selecting time and place for the hearing.

**3. Committees.**—The function of the Committee on Member Firms is to ensure that member firms observe the regulations of the exchange. Even though a firm finances the purchase of a seat for a partner, the membership represents a personal franchise of the partner. Should the member sell his seat either voluntarily or involuntarily while in debt to the exchange or one of its members, the proceeds of the sale will be used first to pay those debts. On the other hand, the partnership must sign an agreement to the effect that it will assume the risks of fluctuations in the value of the membership where the firm is financing, in part or in whole, its purchase. All members have a right to retain their memberships, subject to making agreed payments to their firms for their seats. These are but a few of the regulations governing member firms.

Trading on the floor of the exchange is governed by rules of the exchange and by rules of the Securities and Exchange commission (SEC). It is the duty of the committee on floor procedure to see that these rules are observed. For example, specialists (see *Classes of Members*, below) are required to file with the exchange a report of all their transactions. These reports are checked for infractions of trading rules.

As with many private corporations, the New York Stock exchange was late in recognizing the importance of its relations with the public. While the exchange has had a public relations department for some time, it originally was concerned only with internal information and relations. With a reorganization in 1938, the exchange showed concern about its relations with the public. It launched an advertising campaign to urge investors to be cautious. It told the public about the purpose of the exchange and how the public could invest in corporate enterprise through careful employment of savings.

The principal function of the Executive Committee is to coordinate the functions of all other committees. Its members participate in the policy decisions of the various departments.

**4. The Trading Floor.**—All trading takes place on the floor of the exchange where there are several large U-shaped posts. Each stock is traded at only one post. The selection of a post for a new issue is based on the relative activity around the several posts as well as the existing location of issues in the same industry as the new issue. In selecting this post, the exchange is interested primarily in preventing congestion on the floor. When, for example, a new aircraft issue is listed, a post is selected around which the activity is relatively light and where no other aircraft issue is traded.

Members who are interested in buying or selling a particular issue will congregate around the post where it is traded. These members constitute what is called a "crowd." The Chrysler crowd, for example, includes all members who are standing at the post where Chrysler stock is bought and sold, and who are participating in the auction process. Some will be bidding for Chrysler stock; others will be offering it for sale. When there is a meeting of minds, a transaction is effected.

Pages, the only other persons allowed on the floor, record transactions as they are effected in the crowd. If the members involved agree that the transaction as repeated by the page is correct, the page walks to the open end of the post and sends the report, via pneumatic tube, to another floor in the building where machines send the report to other cities. In this manner, reports of the latest transactions are flashed to brokerage houses throughout the country.

Along the sides of the floor are several hundred telephones over which clerks receive orders from member firms. Since the floor of the exchange is large, two huge boards on the walls provide a medium of communication between a clerk and his broker. Each member has a number assigned to him. When a clerk receives an order on the telephone he flashes the number of his broker on this board. His broker, observing the signal, goes to his booth, picks up the order, and takes it out into the appropriate crowd. Telephone clerks are not allowed on the floor.

## C. CLASSES OF MEMBERS

**1. Commission Brokers.**—These members make up the largest group among the members of the New York Stock exchange. They are partners of member firms and own seats on the exchange in order to execute orders for their customers. They are their customers' agents; through them customers from all over the world can meet at one place and trade in securities. For their services they charge commissions which constitute the principal source of income for member firms.

**2. Specialists.**—Specialists are another group of members. For each stock listed there is a specialist. There may be more than one for one stock and several stocks may be handled by one specialist. For each stock the specialist has a book in which he enters all limited orders (see *Types of Orders*, below) given him by commission brokers as well as the time they were received. He stands at his post all day; therefore, if he specializes in more than one issue, they must all be located at his post. Whenever he executes an order for another broker, the specialist charges a commission, but a customer whose order is executed by a specialist does not pay this commission. Instead, the commission broker must pay it. Therefore, the latter will give orders to specialists only when he cannot himself gain an execution in a reasonable length of time. The origin of the function of the specialist dates back to the days when trading took place in the street. Some of the older brokers who could not stand the physical strain of hurrying from one place to another decided to stay in one place and specialize in the trading of one or more issues.

**3. Two-Dollar Brokers.**—A third group of brokers is the so-called two-dollar brokers. They are not associated with member firms; they make their livelihood by executing orders for commission brokers who may become too busy to handle all their orders quickly. Suppose a commission broker receives two orders at the same time, one to buy 500 shares of an automobile manufacturer and the other to buy 100 shares of an aircraft builder. Since the posts at which these two stocks are traded are some distance from one another, he elects to execute the larger order himself and gives the smaller order to a two-dollar broker to execute. The latter charges a commission for his services equal to those charged by the specialist. The two-dollar broker also executes orders for members while the latter take time out for lunch or while they are away from the floor for other reasons. Several members of the board of governors are two-dollar brokers.

**4. Odd-Lot Dealers.**—The fourth group includes odd-lot dealers and brokers. The dealers act as principals in making up so-called round lots—100 shares or multiples thereof—to trade in the auction market from the odd-lot orders—less than 100 shares—which are received by member firms. While they act as principals, their primary function is to service the odd-lot customer and their main source of income is the commissions they charge for this service.

**5. Traders.**—The traders represent the final group of members. They buy and sell stock for their own account with the hope of making speculative profits. They are small in number and account for only a small percentage of the total transactions.

## D. TYPES OF ORDERS

The market for every security listed on an organized exchange is an auction market. At all times there is a quotation for these securities which consists of the best bid and the best offer. The best bid comes from that broker in the crowd who is willing to pay as much or more than any other person for that stock and the best offer comes from the broker who is willing to sell stock at a price below that of any other offer. These brokers are buying and selling stock for their customers, and the prices which they bid or ask are those specified by the customer. All stocks are quoted in terms of dollars per share. Except for very low-priced stocks and those traded on the National Stock exchange, the smallest change in price is one-eighth of a dollar. Thus, a stock could sell for 50, 50½ or 50¼. All orders in the auction market are for 100 shares or multiples thereof, except for some inactive stocks traded at post 30 where the unit of trading is less than 100 shares. Every stock has a symbol which identifies it and which speeds the

handling of orders and reports of transactions.

**1. The Quotation.**—Let us suppose that the last price for GM (symbol for General Motors) was 50 and that several brokers in the GM crowd want to buy it. The highest bid is made by one broker who is willing to pay 49¾. Since no other broker is willing to pay as much, this broker's bid constitutes part of the quotation, even though there may be others willing to pay 49½ or below. There are other brokers in the crowd who want to sell GM. The one who is willing to sell at the lowest price constitutes the best offer. Suppose he offers GM at 50¼. Others may be offering to sell at 50½ or above. The quotation for GM, however, is 49¾–50¼, or the best bid and best offer received from brokers in the crowd. This quotation appears above the post where GM is traded and is kept up to date by the specialist or his clerk inside the post. If the spread between the bid and ask prices for GM is too great to constitute a good market for the stock, it is the duty of the specialist in GM to bid higher than the best bid or to offer to sell at a price below the best offer. It is possible that several brokers may be bidding for GM at 49¾. In this case, the broker whose bid came first is the one who will have the opportunity to purchase the stock if anyone offers to sell at that price.

A complete quotation includes the size or the amount of stock available at the best bid and at the best offer. If there were three brokers each offering to buy 100 shares of GM at 49¾ and two brokers willing to sell 100 shares at 50¼, then the complete quotation would be 49¾–50¼, 300–200. The size of the orders does not appear on the post where the bid and offer are shown. A broker may wish to know the size, however, and he will ask the specialist for that information. The specialist will reply: "49¾ for 300, 200 at 50¼." The size is often an important factor in measuring the strength or weakness of the market at any one time. If there are considerably more shares available at the best bid than at the best offer, the market is stronger than if the reverse were the case.

The quotation may change even before the next execution. One of the brokers in the crowd may better the best offer by asking 50½. The quotation now becomes 49¾ for 100, 100 at 50½, which narrows the spread between the bid and ask and brings an execution nearer to realization. The broker who offered to sell at 50¼ may now decide that he may be able to get a better price and cancels his offer. Since there is still one broker in the crowd who is willing to sell at 50¼, his offer now becomes the best offer and the quotation is changed to 49¾–50¼. These are the two principal methods by which a quotation changes before an execution is realized—through a better bid or offer or through a cancellation. Most of these bids and offers are made by commission brokers on behalf of their customers. If a customer changes his mind and bids a higher price he tells his broker to change his bid and this order is sent to the floor of the exchange where the commission broker receives the instructions to change the bid.

Suppose a broker who is bidding for GM now decides to meet the best offer. If the quotation is 49¾–50¼, the broker says: "50¼ for 100," meaning he is willing to buy at that price. An execution is effected at 50¼, and the quotation now is changed to include the next best bid and offer. If another broker is willing to bid 49½ while another offers at 50½, and these constitute the best bid and offer, the quote is changed to 49½–50½. It is possible, however, that an execution will leave the quotation unchanged, for there may be more bids and offers at the same price.

**2. Market Orders.**—The simplest type of order which a customer can enter is a market order. If a customer enters a market order to buy 100 shares of a certain stock the commission broker will take that order into the crowd and announce his willingness to buy at the best offer. If the quote is 49½–50½, he will buy stock for his customer at 50½, for he holds a market order and must meet the best offer. If a customer wishes to sell 100 shares at the market, the broker enters the crowd and sells 100 shares at 49½, which is the best bid. This is the only course of action a broker may take when executing a market order. A customer who enters a market order receives the worst possible price, from his point of view, within the range of the quotation. The broker, on the other hand, dares not try to get a better price for his

customer through the auction process without specific instructions to do so. If he decided not to execute the market order at 50½, but instead bid something less, trying to get a better price for his customer, it is possible that no one would offer to sell at less than 50½ and that, while he is holding the order, the broker who is offering to sell at that price cancels that offer and offers stock at 50½ instead. If the offering price continues to advance without an execution, the customer's broker may be forced finally to meet an offering price higher than the one that existed when he entered the crowd. If this happened, the broker would be forced to account for the difference to his customer out of his own pocket. For example, if he is forced to buy at 50½ because he withheld a market order which could have been executed at 50½, he must make up ½ of a dollar per share from his own funds. All orders are time-stamped when they reach the floor, and it is a simple procedure to check the quotation at the time the order was received. For this reason, a market order should be executed immediately. The customer who enters the market order should be aware, however, that he must meet the best offer, which is the highest price in the quotation range, if he wishes to buy stock and that he must meet the best bid, which is the lowest price in the quotation range, if he wishes to sell.

**3. Limited Orders.**—Any order other than a market order is called a limited order. Referring again to the hypothetical quotation of 49½–50½, a customer may wish to buy 100 shares but does not want to pay 50½, the price he would be forced to pay if he entered a market order. He is willing to pay no more than 49½, so he enters a limited buy order at that price. When the telephone clerk receives this order on the floor, he may decide not to bother his broker, who may be executing market orders in other crowds, so he sends the order to the specialist via pneumatic tube. The specialist receives the order, time-stamps it, and enters it in his book. The order will not be executed until someone offers to sell at 49½. This may take several hours or even days. The customer will be notified as soon as he gets an execution, but he cannot expect to get confirmation within a few minutes after he enters the order, as is the case for a market order. If he has decided that he is unwilling to pay more than 49½ he must be willing to wait until someone offers stock at that price. It may be possible that he will get an execution below that price, for a limited order becomes a market order as soon as an execution of 49½ is reached. It is a modified type of market order, however, for it cannot be executed above 49½ but can be executed below that price. The procedure for executing a limited order to sell is exactly the same as that for limited buy orders. The former, of course, is entered above the market price, for the customer wants to receive more for his stock than the best bid. A customer who wants to buy stock but does not want to meet the best offer may nevertheless enter a limited order which betters the best bid, such as a limited buy order at 50. In this case, the quote would be changed to 50–50½, with the bid representing the customer's order. Under such circumstances, the broker might take the order into the crowd and bid 50, rather than give it to the specialist, in order to save the commission he would have to pay the specialist for executing it. Where a customer enters a limited order to buy at a price which is above the best offer, because he did not know the quotation at the time, the order will be executed as a market order.

**4. Stop-Loss Orders.**—Another type of limited order is called a stop-loss order. Suppose a customer buys 100 shares of a certain stock at 50 but is unwilling to take a loss of more than three dollars per share. He may protect himself by entering a stop-loss order at 47. This order is entered on the specialist's book. If the stock falls to 47 the specialist tries to sell it. This type of order, however, does not protect against a loss of more than three points, for it becomes a market order as soon as the stock drops to 47. If the stock continues to fall in price, it is likely that the best bid will be something less than 47 after an execution at that price. Since the stop-loss has become a market order, it will be executed at the best bid, which may be 46½.

The stop-loss order is also used to protect profits. If stock bought at 48 goes to 53, the owner may wish to hold the stock and

still protect part of his paper profit. In this case, he might enter a stop-loss order at 50. Should the stock fall back to 50, it will be sold at or near that price and the owner will realize some profit. If, on the other hand, the price of the stock continues to rise, the owner can enter stop-loss orders at progressively higher prices, thus protecting more of his profits while letting them increase.

It is also possible to enter a buy stop-loss order. This type is used to limit losses or protect gains when a customer has sold short. A customer sells short when he sells something he does not own. Of course, he must deliver stock when he sells it, and since he does not own it, he borrows some stock from someone who does and delivers this stock to the buyer. At some time in the future he will be forced to buy the same number of shares from someone else in order to repay the lender. An individual sells short when he believes a particular stock will fall in price. He sells short at a relatively high price and hopes to cover his short sale—buy the stock later to repay the lender—when the stock has fallen to a lower price.

Suppose an investor sells a certain stock short at 50. He decides to limit his losses to three dollars per share, so he enters a buy stop-loss order at 53. Should the stock rise to 53, his order will be executed. Should it drop to 45, however, he could enter a buy stop-loss order at 48, thus protecting two points' profit per share while letting his profits build up if the stock continues to fall.

**5. Stop Orders.**—Stop orders, of which stop-loss orders are a type, are often employed by chartists or persons who believe that a stock has resistance levels. An investor may feel that if a certain stock does not reach 50 it will probably go down to 40. He may also feel that if it does reach 50 or above it may go to 60. If the stock is selling at 48 the investor may enter a buy stop order at 51. This order is entered on the specialist's book. As soon as it reaches 51 the specialist will buy 100 shares. According to the analysis the stock will now probably go up to 60. If the stock does not reach 50, the specialist will not buy it and the stock, if it moves as anticipated, will go down to 40. The buy stop order differs from the limited buy order in that it is entered above the market while the latter is entered below the market. It differs from a buy stop-loss order only in its use. The former is used when one has no position in the stock. The latter is used when one is short in the stock. A sell stop order, on the other hand, is entered below the market and the procedure is reversed.

**6. Time Limits.**—A customer may wish to limit the length of time on a limited order. He may do so by telling his broker that the order is good for today only, good this week (G.T.W.), good this month (G.T.M.) or good until canceled (G.T.C.). If the order is not executed within the time limits, it will be canceled. A customer may cancel an order at any time, however, even though he did not so designate at the time it was entered. If orders do not carry a specific time limit, they are considered open orders. One danger of an open limited order is that the customer may forget about having entered it. It may be executed for him later, to his surprise. Most brokerage houses guard against this possibility by sending monthly notices to customers concerning open orders which they are holding for them.

The price of certain types of limited orders may be changed by the specialists when a stock sells "ex-dividend" (see *Glossary*, below.) If a stock is paying \$1.25 every quarter, it will drop in price one and one-quarter points when it sells ex-dividend. This drop is exclusively due to the stock going ex-dividend, not to any fundamental or technical factors in the market. Therefore, on limited open buy orders and on limited open sell stop orders the specialist will reduce the price by one and one-quarter points. This accounts for the drop in the price of the stock due to its selling ex-dividend, and leaves the order, therefore, in exactly the same position as it was previously. Stop orders to buy or limited sell orders are not reduced. Where the dividend is in a fraction not divisible by the minimum trading range, the price is reduced to the nearest higher fraction.

## II. GREAT BRITAIN

**1. Historical Background.**—London was once the greatest of the world's stock exchanges in the range and volume of its transactions; and even after New York's rise to rival importance in the 20th century the range of London's business covered every corner of the earth and every class and type of security. It was not until the latter part of the 18th century that the London stockbrokers definitely formed themselves into a stock exchange with premises of their own. They had been in the habit of meeting and doing business in the Royal exchange and neighbouring places, but in 1773 those who had hitherto met at Jonathan's (a coffeehouse in Change alley) moved to a room in Sweeting's alley to which the name of the stock exchange was formally given, the building becoming known as the Stock Exchange Coffeehouse or tavern. Business grew apace, and in 1801 a group of members raised £20,000 of capital in 400 shares of £50 each for the purpose of providing an adequate building and acquired a site in Capel court, Bartholomew lane.

The new building was opened in 1802. At that time the members of the stock exchange numbered about 500. Rules were drawn up for the conduct of business and for regulating membership of the house. It was provided that all future members should be admitted by ballot, and members were required to pay a subscription of ten guineas each for themselves and five guineas for their clerks. It was the general intention that the shares should be held by members, but there were always a large number of members who did not hold shares. The first extension was made in 1823 when the floor space was nearly doubled by the addition of a second room for dealings in foreign stock. In 1854 the two rooms with some small additions were rebuilt as one in the form of a dome with two transepts. Several subsequent extensions of this building were made, the principal one being in 1885 when another dome was added. In 1953 a public gallery was constructed. The stock exchange building occupies the greater portion of the triangular area formed by Throgmorton street, Bartholomew lane and Old Broad street.

**2. Organization.**—The control and administration of the assets and activities of the London Stock exchange have from June 1945 been in the hands of a body called the council of the stock exchange. After June 24, 1954, by which date the last ex officio members dating back to an earlier regime were compelled to retire, all members of the council (numbering from 30 to 36) were elected annually from and by the general membership. The introduction of the council to replace the earlier administrative bodies was accompanied by other revisions. Among these was the cessation of the earlier practice of distributing profits to the proprietors. In Dec. 1947, paid-up capital was reduced from £720,000 to £1,000 by writing down the paid-up capital value of each share from £36 to a nominal value of 1s. In compensation for the reduction of capital and surrender of rights to dividends on these 1s. shares, members received two £4 cumulative redeemable annuities for each share held. These annuities are redeemable by purchase at any time and any price, or by drawings after March 1, 1958, at £100 for each annuity; and they may be reissued any time. One important result of this change was that the purchase of a share qualification for membership was abolished. It was provided that each member should hold at least one share for voting purposes, to be obtained on application to the council.

The discipline of the stock exchange is very strict, and the council deals severely with members guilty of improper conduct. It has power to suspend or expel a member. The council also settles disputes between members and between members and their clients.

Securities cannot be quoted on the stock exchange except by permission of the council, and conditions have to be fulfilled before that permission is granted; this regulation marks a state of affairs sharply different from, and very much more satisfactory than, the ruling prior to World War I by which any security could be dealt in without permission and grave abuses occasionally arose.

**3. Membership.**—The annual income of the stock exchange is derived from the annual subscriptions of members and their clerks, entrance fees paid by new members and quotation fees. Since 1904, the only method by which a person may ordinarily become a

member is to obtain a nomination (by purchase) from an existing member who must retire in his favour. Nominations may be obtained from a former member, or, if he has not disposed of his nomination, from the legal personal representative of a deceased member. Nominations, which are personal and nontransferable, are usually purchased, and the cost may range between £40 and £2,000. A candidate for membership must be recommended by three members, who become sureties for him during the first four years for £500 each, or £1,500 altogether. A certain number of clerks who have completed four years' service are admitted each year without nomination; for these, only two sureties of £300 each are needed, their liability extending for four years. Membership is for 12 months only, so that everyone who wishes to remain a member must apply to the committee for reelection. By the 1960s there were approximately 3,400 members of the stock exchange, employing more than 2,000 clerks (of whom about 1,200 had right of entry to the floor of the house).

**4. Business.**—By custom, each market has a special place allotted to it; for instance, the space immediately in front of the World War memorial is the market for British government securities and other gilt-edged stocks. Dealers or jobbers in these securities take up their posts in this space every day, and dealers in other classes of securities similarly occupy the floor space allotted to their particular markets. In this way the locality of a market can be readily and easily found by the brokers who go to the house to buy or sell securities for their clients. There is an important distinction between brokers and dealers. Brokers are not allowed to deal on their own account, nor can dealers act as brokers—this is the vital difference. The dealer or jobber occupies a position similar to that of the wholesale dealer in commodities. He deals in a particular group of securities, say oil shares, and his function is to buy oil shares when they are offered to him and to sell them if they are wanted. He quotes two prices for a share, his buying price, which is the lower, and his selling price, which is the higher, and the difference represents his profit. A broker acts for the public which desires to buy or sell securities. Ordinarily, both for buying and selling securities, though in certain circumstances only for buying, a commission is charged by the broker.

When a broker has bought or sold shares he usually enters on a printed slip the name of the shares and the price at which the business was done; he then signs the slip and drops it into one of the boxes provided for the purpose inside the house. These slips are all collected, and the prices are printed that evening in the official list. This is what is known as the marking of bargains.

Except in the gilt-edged market, every bargain that a broker executes for his client is "for the account," unless otherwise specified. This means that the bargain will be completed (*i.e.*, the stock handed over and paid for) on the next settling day. The usual period of the account is a fortnight, but there are four 21-day accounts in the course of a year. Settling days are usually fixed for a Tuesday; the passing of tickets—ticket day—takes place on a Wednesday; and making-up day is Tuesday, prices for the settlement of current securities being fixed in the morning. A broker on executing an order for a client sends him a contract note which sets forth the details of the transaction, the price obtained or to be paid, the amount of brokers' commission, stamp and transfer fee and the amount of the contract stamp. Later, as settlement day approaches, a further note is sent to a client who has bought stock, requesting him to forward the purchase money. The bargain may be "closed" in the same account, that is, stock purchased may be sold (and vice versa) before settlement is due; in this case the client is not required to pay the full consideration (or deliver the stock), but merely receives or pays the difference between the buying and the selling price.

This latter procedure is one of the commoner methods of speculation. Speculation differs from genuine investment in that the genuine investor normally buys for income purposes or steady capital appreciation, whereas the speculator operates in anticipation of a quick movement in the share price. He may buy in anticipation of a rise or sell in anticipation of a fall. He may do this in the hope of closing the bargain at a profit before he is

called upon to pay for or to deliver the stock. Before 1930 facilities for buying and holding stock without paying for it (*contango*) and for lending shares to speculators who had sold them without possession (*backwardation*) were commonly employed. Since then, although these facilities are available, such transactions are less common. In 1958 reintroduction of options offered alternative facilities that largely replaced *contango* and *backwardation*.

(C. J. M.; E. M.; B. P. W.)

### III. OTHER EXCHANGES

There are three types of markets on the Paris bourse: the official market or *parquet*; the curb market or *marché des courtiers*; and the free market or *marché hors-cote*. The official stockbroker or *agent de change* on the *parquet* has a transferable monopoly (now subject to governmental sanction), must act only as an agent and must not recommend the purchase or sale of securities to his clients. He is a sworn government official, subject to close supervision. Business is divided into cash (*au comptant*) transactions and transactions for the term or for future delivery and settlement (*à terme*). Both investors and speculators use the more advantageous term market. At the end of each month, all open accounts are settled through the central liquidation service. On the curb market and the free market the *courtiers*, like the *agents de change*, have a transferable monopoly, which, however, covers securities not quoted on the official market. They are not government officials but only commission agents. The free market comprises all shares quoted neither on the *parquet* nor on the *marché des courtiers*. A new share is generally first quoted on the free market and then, as it steadies, rises to the *parquet*.

During their occupation of the Netherlands in World War II the Germans tried to disrupt business on the Amsterdam stock exchange as much as they could; not until 1953 were the old regulations re-established. The Stock Exchange union, though a private association, is subordinate to the minister of finance, who has the right to regulate the exchange's opening and closing and to approve the listing of new securities. The Amsterdam banks are members of the stock exchange, so that many transactions are effectuated not on the exchange itself but in the banks; such internal clearings, however, are based on the official quotations and governed by the regulations.

The most important Italian stock exchange is in Milan. The rules governing Italian stock exchanges are fixed by law; they are established and supervised by the government and the *agente di cambio* is a public official appointed by presidential decree, with a rate of commission fixed by the treasury. Direct negotiations by word of mouth can be conducted only by these *agenti* or their representatives. Methods of trading include: transactions *a contanti* (for cash), almost entirely confined to securities of fixed value; transactions *a termine* (for the term), concerned with shares, i.e., the majority of business; and transactions *a premio*, of which option dealing alone is fairly widespread. Settlement takes place at the end of the month, through clearing houses.

### IV. GLOSSARY OF STOCK EXCHANGE TERMS

**Accounts.**—In British usage, accounts are the periods into which the stock exchange year is divided. Usually 24 in number, they are normally of 14 days' duration; sometimes they are of 21 days because of holidays.

**Arbitrage.**—The adjustment of anomalies in values between two different markets, e.g., between London and Johannesburg. (See *ARBITRAGE*.)

**Bear.**—Originally a term limited in its application to a person who sold shares which he did not own, in the belief that he could buy them at a lower price when the time came for delivery. It has since been extended to cover any market operator who anticipates that prices will fall. Cf. *Bull*.

**Bearer Stock or Bond.**—Securities for which registration of ownership by the company concerned is unnecessary for a good title to pass from one person to another.

**Bid.**—Term indicating the price one is willing to pay for shares. Also the price which a buyer has declared that he will pay; commonly, therefore, the lower of the two prices quoted by a jobber or dealer.

**Blue Chip.**—An American expression also widely used in Britain to describe ordinary shares of the highest investment calibre.

**Bonus Issue.**—See *Capitalization Issue*.

**Bourse.**—A European term for a stock exchange, derived from French usage and first used for the Paris exchange.

**Bucket Shop.**—This term refers to a type of brokerage house that once flourished but is now illegal. It was not a brokerage firm in the true sense, for its operators merely accepted orders from customers without placing them on the market. The bucket shop operator gambled that customers were wrong in their judgment of the market, and that he would later be able to buy or sell the stock at more favourable prices.

**Bull.**—An investor who expects that prices will rise. The term was formerly used chiefly to describe speculators who bought shares which they hoped to sell at a profit before settlement day, when they would have to pay for them. A bull market is one in which prices are rising.

**Buying Limit.**—An order to buy shares at a price below the current market price. It is given to a broker to enable the would-be purchaser to take immediate advantage of a fall in price—which may be short-lived—without the necessity of the broker's referring to the client.

**Buy or Cancel.**—A customer may give his broker an order to buy today or cancel. If the order is not completed that day, the order is automatically canceled.

**Capital Gain.**—A profit from the sale of securities or other capital assets. See *CAPITAL GAINS, TAXATION OF*.

**Capitalization Issue.**—The official description in Great Britain of a scrip issue; also known as a bonus issue or, in the U.S., as a stock dividend. This expression means the issue by a company, to existing shareholders, of shares for which payment is not required. It represents the capitalization of reserves; to the extent that these have been accumulated from annual profits, it is a formal acknowledgment that the ploughing-back of profits in past years is the equivalent of the reinvestment of those profits in the company.

**Chart Reader.**—Some investors and speculators employ charts which depict such data as the daily market averages, the market prices of individual stocks, or the volume of sales. They think they perceive patterns in formation, the completion of which can be anticipated profitably.

**Close to Close.**—A price made by British jobbers indicating that they are prepared to deal  $\frac{1}{4}$  of a £ (i.e., 3½d.) either side of a specified price. For example, "seven-eighths close to close" = 17s. 2½d. to 17s. 9½d.

**Closing.**—Buying or selling to close a bargain opened in the same account.

**Cum.**—Prefix meaning "with." "Cum all" means "with all advantages"; cum cap., "with capitalization rights"; cum div., "with dividend"; cum rights, "with rights."

**Customers' Man.**—The customers' man is the "contact man" for the brokerage firm by whom he is employed. He accepts and solicits orders from customers, advises them in their trading, and comments on the market outlook.

**Daylight Trading.**—Daylight trading refers to the practice of disposing of all stocks purchased during a single session.

**Dealing for New Time.**—A British term for the purchase or sale of securities during the two market days that precede the first day of an account. In "dealing for new time" the same stamp duty and commission concessionary rules apply as for "deals for the account." The jobber will, however, quote a higher price.

**Discretion.**—Concession of freedom by a client to a broker to act as he thinks fit, generally limited to a stated margin.

**Dollar Averaging.**—The investment of the same number of dollars in a given stock at regular intervals regardless of the price of the stock. Advocates of this procedure maintain that, over the long haul, it yields better results than the practice of waiting to buy until the stock seems to be low.

**Dow-Jones Averages.**—In the United States, the average prices of the three categories of stocks—industrials, railroads, and utilities. The industrial average is based on the selling prices of 30 well-known industrial stocks; the rail average is based on the prices of 20 representative railroad stocks; and the utility average on the prices of 15 utility stocks (gas and electric companies). There is also a comprehensive average of all the 65 stocks combined.

**Either Side.**—Term used to indicate that a quotation is  $\frac{1}{2}$  (or 7½d.) either side of a specified price. For example, "either side of the seven" means either side of  $\frac{1}{8}$  and would indicate a range of from  $\frac{1}{16}$  to  $\frac{3}{16}$ . If the "big figure" which (by implication) precedes it were 3, then the price quoted would be 68s. to 69s. 4½d.

**Ex-dividend.**—When a company announces a dividend to stockholders of record as of a certain day, the books of the corporation are closed on that day for the payment of the dividend. Purchasers of the stock after the books are closed do not receive the dividend and the stock is said to sell "ex-dividend."

**Flat.**—Bonds are usually quoted and sold "and interest." Bonds in default, however, are sold "flat," since no interest is being paid.

**Floating Supply.**—The floating supply is that portion of the outstanding stock which is usually held for speculative purposes, and which is available for trading purposes at or near the current market price.

**Gilt-edged.**—Originally, writing paper of the finest quality, and hence first-class bills of exchange. Now most commonly applied to British government securities, dominion and colonial government stocks, United

Kingdom corporation issues, etc.

**Growth Stock.**—The stock of a company which gains in value over a period of time more than the general market. The company usually has sales and earnings growth prospects which are greater than those of the economy.

**G.T.C.**—This is an abbreviation for "good 'til canceled" and refers to a limited price offer which remains open until canceled.

**Kaffirs.**—Familiar name given to South African gold mining shares. The market in which they are dealt—the particular spot inside the stock exchange premises—is sometimes called the Kaffir circus.

**Loan Crowd.**—The loan crowd is composed of exchange members who are willing to borrow or lend stocks.

**Long.**—A buyer or holder of securities is said to be "long" of the market or "long" of stock if he has more of a particular security than he has contracts to deliver. The longs are usually those who have bought expecting a rise in prices.

**Margin.**—When a customer borrows money from his broker to buy stocks, he is said to have bought stock on margin. In the United States the federal reserve board sets limits as to how much a broker can lend on stock transactions. See MARGIN.

**Miser.**—A security which, although too speculative to justify a large holding in relation to the size of the total portfolio, is recommended for "mixing purposes," i.e., for raising the average yield.

**New Time.**—This British expression describes the account, also called "new account," following the one in which dealings are taking place. For the two days preceding the new account, brokers may deal for "new time" so that settlement does not take place until the settlement day of the following account.

**Not to Press (NTP).**—Short for "not to press for delivery"; expression used when a jobber sells shares which he has not got and which he believes may take him some time to acquire.

**Offer.**—A term indicating the price one is willing to sell his shares for. It is synonymous with "ask," and is distinguished from "bid," the price one is willing to pay for shares.

**Option.**—Literally, a right to choose. In stock exchange matters it refers usually to "single options" and "double options." Single option means the right (purchasable for a consideration) to choose whether or not at a given future date to buy ("call option") a given security for a given price; or, similarly, the right to choose whether or not to sell ("put option") a given security for a given price. In both cases the right must be exercised within a given period, normally three months. A double option, sometimes known as a straddle, gives the right to decide at the end of the period whether or not to buy or sell.

**Price-Earnings Ratio.**—The ratio between the selling price of a stock and the company's earnings per share. Many investors feel that a stock that sells for more than 20 times its earnings is overpriced.

**Rights Issue.**—An issue of shares to existing shareholders in a fixed proportion to those they already hold, to be purchased at a given price, which is generally below the market price of the existing shares.

**Selling Against the Box.**—When the holder of securities, possessing stocks which he is holding "long," sells an equal amount of stock "short," he is said to be "selling against the box."

**Short.**—A buyer or holder of securities is said to be "short" of the market or "short" of stock if he has contracted to deliver at some future date more of a particular stock than he holds. The shorts are principally those who have "sold short" in anticipation of a drop in prices, in which event they would buy at the lower price in time for delivery.

**Split.**—Frequently when the price of a stock rises to levels which discourage the average investor, the company may split its shares to reduce the price. For example, a stock selling at 200 may be split four shares for one and the price would drop to 50. The old stockholder now has four times as many shares but they are worth no more in total than before the stock split.

**Spread.**—The difference between the bid and asked prices.

**Stop-loss Order.**—The stop-loss order or stop order is an order to sell at the market if and when a transaction occurs at or below a stated price. By using "stops" holders of stocks limit their losses in a declining market.

**Ticker.**—A term used to describe the transmission of stock prices to brokerage offices all over the country. Appearing on the ticker tape are prices of securities which represent transactions completed only minutes before.

**Warrant.**—A certificate giving the holder the right to purchase a fixed number of shares of stock at some future time at a fixed price. It is properly known as a stock purchase warrant.

**Wash Sale.**—When two individuals agree to buy from or sell to each other securities to stimulate market activity, and where no intention to exchange goods or money is present, a wash sale is said to have been effected. This is an illegal transaction on the exchange floor and members are liable to expulsion when discovered engaging in it.

**Yield.**—Interest on bonds or dividends on stock expressed as a percentage of the amount invested on an annual basis.

**STOCKHOLM**, a *län* (county) of east central Sweden, surrounding the capital city, which is the seat of its *landshövding* (governor) but is administratively separate from it. Area 2,997 sq.mi. (7,762 sq.km.). Pop. (1960) 461,082. The county, comprising parts of the provinces of Uppland and Södermanland, with the skerries and larger islands of the Stockholm Archipelago (*skärgård*), is dominated by the capital with its surrounding "new towns" and older garden suburbs (see STOCKHOLM [city]). The former fishing centres in the *skärgård* have been abandoned or have become small summer resorts, such as Vaxholm with its 16th-century island fort. Other resorts are the old towns of Öregrund and Östhammar in the north, and, of more recent (late 19th century) origin, Saltsjöbaden, southeast of the city. Sigtuna, on an arm of Mälaren, 25 mi. (40 km.) NNW of Stockholm, is one of the two oldest towns in Sweden (the other being Lund in Skåne; both were founded c. 1000). Industries in the *län* include shipbuilding, food processing, and engineering, the chief industrial centres being Södertälje, Solna (*qq.v.*), Sundbyberg, Lidingö, and Nacka. Nynäshamn, in the extreme south, has an oil refinery. The *län* was created in 1641 but during 1649–1714 was united with Uppsala *län*. (A. C. O'D.)

**STOCKHOLM**, the capital city of Sweden, is in east central Sweden, at the junction of Mälaren (Lake Mälär) and Saltsjön (an arm of the Baltic). Pop. (1960) 808,494; (1964 est.) 796,000. Land area 72 sq.mi. (186 sq.km.). Greater Stockholm, which includes 18 surrounding communes, covers a land area of 522 sq.mi. (1,354 sq.km.). Pop. (1960) 1,139,000; (1964 est.) 1,160,000.

On a number of islands and peninsulas, the town is often called "the City on the Water" or "the Venice of the North." Its medieval heart, Gamla Staden (the Old Town) lies on Städsolmen, a small island formed by two short streams through which the waters of Mälaren flow into the Baltic with its thousands of skerries (the Stockholm Archipelago). Städsolmen and the adjacent Riddarholmen, Helgeandsholmen, and Strömsborg islet are known as the "town between the bridges." The Old Town still partly retains its medieval plan, with narrow streets and ancient buildings. There stand the Italianate Royal Palace (rebuilt, 1697–1754) of Nicodemus Tessin the Younger, Stockholm's cathedral, Storkyrkan, founded in the 13th century (but rebuilt later), Riddarhuset (the House of Nobility), from the mid-17th century, and the Stock Exchange—also the seat of the Swedish Academy—built in the 1770s. Along the eastern shore runs the old quay, Skeppsbron, with its trading houses mainly from the 17th and 18th centuries, where stands J. T. Sergel's statue of Gustavus III (1808). On Helgeandsholmen (the Island of the Holy Ghost) north of the palace are the late-19th-century Riksdagshuset (the House of Parliament) and Riksbanken (the National Bank). In the Old Town and on Riddarholmen to the west are most of the government departments, many being housed in 17th-century palaces. On the site of an old Franciscan monastery lies Riddarholmskyrkan, the royal memorial church since the time of Gustavus II Adolphus (d. 1632).

From the Royal Palace, the late-18th-century Norrbro (North Bridge) leads over to Norrmalm, the commercial centre of Stockholm with lively business streets, such as Drottninggatan, Regeringsgatan, Kungsgatan, Vasagatan, and Sveavägen. Opposite the palace, at the bridge abutment, is Gustav Adolfs Torg (square) with an equestrian statue of the king (1796), flanked by the Foreign Office (late 18th century) and the Royal Opera (opened 1898). East of the opera is Karl XII's Torg and Kungsträdgården (the King's Garden), a popular meeting place in the summer with concerts, variety performances, and exhibitions of modern handicraft. There are statues of Charles XII and Charles XIII, and the romantic Molin Fountain (1873). Alongside Kungsträdgården lie Jakobskyrkan (consecrated 1643), several large banks, and Stockholm's largest department store, Nordiska Kompaniet (NK).

On the waterfront east of the opera are the Grand Hotel, with a magnificent view over central Stockholm, and the National Museum (1866), with large collections of Swedish and foreign art (chiefly 17th–19th centuries). A bridge leads to Skeppsholmen and Kastellholmen, formerly a naval base, where the Modern Mu-

THE ROYAL PALACE ON THE CITY ISLAND AS IT APPEARED IN THE EARLY 17TH CENTURY BEFORE IT WAS DESTROYED BY FIRE IN 1697; ENGRAVING FROM THE "INVENTARIUM SVECICAE" BY J. L. GOTTFRIED, 1632

seum of 20th-century art and the East Asia Museum are accommodated in old military buildings.

To the west of Lower Norrmalm, on the site of an old convent, the 16th-century (rebuilt) Klara Kyrka stands in a beautiful churchyard and contains the graves of several poets, including Carl Michael Bellman (*q.v.*). This area is traditionally the centre of the newspaper and printing industries, but during the 1960s these were being transferred more and more to outer districts. Farther west, in Vasagatan, is the Central Railway Station. During the late 1950s and early 1960s the central part of Norrmalm was entirely rebuilt as a modern shopping and business centre (*Hötorgs-city*), featuring five 18-story office blocks and a pedestrian mall (*Sergelgatan*) with shops on two levels. In *Hötorget* (the Hay-market) stand the neoclassical Concert Hall (1926), with Carl Milles' famous Orpheus group in front, and the large department store PUB. Farther north are *Handelshögskolan* (the School of Economics) and the Town Library, both from the 1920s, and Stockholm University, accommodated in a number of buildings around the Old Observatory (*c.* 1750). At the northern end of *Sveavägen* is the Wenner-Gren Centre for international scientific research. West of *Brunnsviken* lie the Medical University (*Karolinska Institutet*) and *Karolinska Sjukhuset* (Caroline Hospital). Nearby is the large Haga Park with Gustavus III's pavilion, in late Gustavian style (1790). East of *Brunnsviken* are the Veterinary College, Forestry Research Institute, Royal Academy of Sciences, and the Natural History Museum.

On *Kungsholmen*, a large island to the west, separated from Norrmalm by a narrow channel, stands Ragnar Östberg's famous City Hall (1923). In the vicinity are the Seraphim Hospital (1752), the Royal Mint, and, farther away, *Rådhuset* (the Law Courts [1915]). There are also several large hospitals and schools. The main streets are *Hantverkargatan*, *St. Eriksgatan*, and *Norr Mälarsstrand*, the last-named beautifully situated along *Mälaren* between the City Hall garden and the large modern *Rålambshov Park* with its playgrounds and open-air theatre.

On the Baltic side of Stockholm lies *Östermalm*, mainly a residential area from the latter part of the 19th century, intersected by boulevards and avenues, *e.g.*, *Birger Jarlsgatan*, *Sturegatan*, *Karlavägen*, *Valhallavägen*, *Narvavägen*, and *Strandvägen*. On the western side of *Sturegatan* is the town's largest inner park, *Humlegården* (the *Hopgarden*) in which is the Royal

Library (1878). In *Valhallavägen* are the Technical University (1922), the Stadium (built for the 1912 Olympic Games), the Royal Central Gymnastics Institute (1945), the Royal Academy of Music's new school (1957), the School of Arts and Crafts (1959), and Swedish Radio's large establishment. Nearby, *Gärdet*, Stockholm's former drill ground, has been partly taken over for modern housing settlements. In *Storgatan* are the National Historical Museum and Royal Mint Collection (the latter containing many Anglo-Saxon coins), and in *Riddargatan*, housed in 18th-century military buildings, is the Army Museum. At *Nybroplan*, where *Birger Jarlsgatan* and *Strandvägen* meet, stands the white marble palace of the Royal Dramatic Theatre (1908), with the small *Berzelii Park* (commemorating the chemist J. J. Berzelius) on the Norrmalm side. *Strandvägen*, *Östermalm's* principal promenade, skirts *Nybroviken* and continues eastward past the Nobel Park along *Djurgårdsbrunnsviken*, a pleasant bay on which are situated the Ethnographical, Technical, and Naval History museums, and a number of embassies, including those of the United Kingdom and the United States. There also is the little English Church (1866) which until 1913 stood in *Vallingatan*.

South of this bay is Stockholm's largest park area, *Southern Djurgården*, which has oak trees 1,000 years old. In the immediate vicinity of *Djurgårdsbron*, which crosses the mouth of the bay from *Strandvägen*, is *Nordiska Museet* (the Nordic Museum [1907]) with the Royal Armoury, the former illustrating Swedish cultural history (*folklore*) and the latter recalling the history of Sweden and its kings from the 16th century. Connected with the Nordic Museum is *Skansen*, the world's first and largest open-air museum; both were founded by Artur Hazelius (1833-1901). There may be seen specimens of old buildings from different parts of Sweden; also there are a well-stocked zoo and several restaurants. Down by the shore of *Saltsjön* is the wharf accommodating the 17th-century warship "Vasa," which sank nearby on its maiden voyage in 1628 and was salvaged almost intact in 1961. Nearby is *Gröna lunds Tivoli*, an amusement park. Farther out the shore is lined with villas. *Waldemarsudde*, the palace of the artist Prince Eugen (1865-1947), containing a collection of modern art, is open to the public, together with its extensive garden and park.

*Södermalm* is a large island rising boldly out of the Baltic. It is connected with the Old Town by the cloverleaf traffic junction at *Slussen* (the Sluice [1935]) and by the *Söderström Bridge* (1959). The main streets are *Götgatan* and *Hornsgatan*—the old southern exits from Stockholm—and *Södergatan* and *Ringvägen*. Along the Baltic lie the harbours of *Stadsgården* and *Hammarby*

(LEFT) GULLERS—RAPHO GUILLUMETTE; (RIGHT) LOUIS RENAULT—PHOTO RESEARCHERS, INC.

(LEFT) MODERN STOCKHOLM, SEEN FROM ROUGHLY THE SAME VANTAGE POINT AS IN THE 17TH-CENTURY ENGRAVING ABOVE; (RIGHT) NARROW STREET IN STADEN, THE OLDEST PART OF THE CITY

and a number of industrial plants. The inner part of the island is mainly residential. Stockholm's City Museum is housed in the former city hall built by the Tessins in the 1680s. Above Årsta Bay, in the southwest, rises Södersjukhuset, a large modern hospital (built 1938-53). Three churches dominate Södermalm: the 16th-century Maria Magdalena (restored in 1825); Katarina, founded in 1656; and the modern twin-towered Högälskyrka (1917-23).

The inner town is linked with the outer districts of Brännkyrka in the south and Bromma in the west by several modern, high bridges famous for their beauty. Early in the 20th century the town of Stockholm bought large properties there on which garden suburbs were erected between 1910 and 1930. Beyond these there were planned and erected during the 1940s and 1950s complete groups of suburbs with their own industrial areas, each individual suburb, with a population of from 10,000 to 15,000, being built around a local centre placed by an underground railway station. Within each suburban group (total population 50,000-100,000) one centre serves as main centre for the whole area. In the west, where this type of planning was first carried through, it is Vällingby (opened 1956). The main centres in the south are Farsta (1960) and Högälen (1959). The construction of other centres continued during the 1960s. A feature of Farsta is that domestic heating is supplied by a nuclear power plant at Ågesta ( $\frac{1}{2}$  mi. from Farsta), first taken into use in 1964.

Immediately southwest of Bromma, on an island in Mälaren and outside Stockholm proper, lies the royal country palace of Drottningholm (17th-18th centuries). Noteworthy is the Court Theatre (1764-66), the auditorium, stage, and stage machinery of which are completely preserved; during the summer contemporary operas are performed there. In the park, laid out in French Baroque style, is the little rococo Kina Slott, a pavilion decorated and furnished in Chinese style.

In olden times, it was primarily the waterways that were used for communication between the various districts inside Stockholm, as well as with the rest of the country and the continent. In the late 1870s tramways were laid and subsequently extended to the garden suburbs mentioned above. The garden suburbs of Djursö, Saltsjöbaden, and Lidingö, which came into being at the turn of the century, were immediately connected with Stockholm by rail. Because of the rapid growth in population and the increasing motor traffic, Stockholm has had to organize extensive traffic installations. Apart from the bridges mentioned above and Slussen, these include the elegant Västerbro (West Bridge [1935]) between Kungsholmen and the south, and the widening of streets in the inner town. During the early 1960s Klarabergsviadukten, a new link between Lower Norrmalm and Kungsholmen, and a new multilane motorway bridge to Lidingö were completed. The first section of Tunnelbanan, Stockholm's underground railway, was laid under Södermalm in the early 1930s. By the mid-1960s it linked the centre of the town with the new suburban districts to the south and west, and extension was continuing. Stockholm has, in addition, a growing number of bus lines which will probably eventually supersede the tramlines. The international airport is at Arlanda, 30 mi. (48 km.) to the north. Bromma Airport is used for internal services only. On the Baltic east of Gärdet are port installations, including the free port and oil harbour, the latter partly built from caissons used in the invasion of Normandy in 1944.

Stockholm city is an *överståthållarskap* (governorship) administratively separate from the surrounding *län* (county) of the same name. It is in the diocese of Uppsala but has a separate consistory presided over by the rector of Storkyrkan. Being the capital, it contains most of the government departments and also the large organizations within the labour market, commerce, and industry, such as the Confederation of Swedish Trade Unions (LO), the Swedish Employers' Confederation (SAF), and others. It is the seat of *högsta domstolen* (the Supreme Court of Justice) and of *Svea hovrätten* (the court of appeal for central Sweden and Gotland). Civil servants constitute an important element in the population, as do also the scientists and teachers attached to the large educational, cultural, social, and scientific institutions. Stock-

holm is the centre of the economic life of the country, particularly where wholesale trade is concerned. Building materials, fuel, and food are leading imports, about half of which are distributed to the environs of the town and to other parts of the country, partly in the form of manufactured goods. In the Stockholm area are such internationally known industrial concerns as Telefon AB L. M. Ericsson, Atlas Copco, Elektrolux, Alfa-Laval, Gasaccumulator (AGA), and Gustavsberg's porcelain factory. The metal industry is the biggest employer of labour, followed by the printing industry.

According to tradition, Stockholm was founded by Birger Jarl about 1250. Its nucleus was a fortress built earlier in the century on Stadsholmen, at the site of the Royal Palace, and the city was surrounded by walls with fortified towers. The origin of the name "Stockholm" ("log island") is doubtful. Churches and monasteries were erected, and as early as 1288 the city was reported as being more populous than most other towns in the country. It had special importance during the Middle Ages for trade on the Baltic and was closely allied to the big Hansa towns. The country's most important articles of export in olden times, iron, copper, and Swedish tar, were shipped from Stockholm.

From the 15th century, Stockholm was the capital of the country. After conflicts lasting many years between the Danes and the Swedes, the town was liberated by Gustavus Vasa in 1523 and has never since been besieged or occupied. It experienced its biggest development about the middle of the 17th century. The central government departments were then placed there, and the population increased rapidly. The old city walls were torn down, and new districts grew up on the area between the old tollgates, north and south of the "town between the bridges." During the 18th century expansion slowed down, but Stockholm became the seat of culture, science, and letters. A new period of development began with industrialism in the mid-19th century, and the population again began to climb. In 1856 it exceeded 100,000, and in 1900, 300,000. During this time redevelopment took place in the area within the old tollgates, buildings were reconstructed, boulevards, avenues, and parks laid out, and many of the educational establishments, museums, libraries, hospitals, etc., were built.

The rapid increase in population continued during the 20th century, but the trend of planning and development during mid-century was to effect a transition from the old pattern of a dominating centre to a much larger urban district with several centres. Thus the population of the city began to decline after 1960, while that of Greater Stockholm continued to rise.

See further SWEDEN; see also references under "Stockholm" in the Index.

**STOCKMAR, CHRISTIAN FRIEDRICH, BARON VON** (1787-1863), Anglo-Belgian statesman, secretary to Prince Leopold of Saxe-Coburg (from 1831 King Leopold I of the Belgians) and unofficial adviser of Queen Victoria, was born at Coburg in Germany on August 22, 1787. He studied medicine and in 1816 became physician to Prince Leopold on his marriage with Princess Charlotte of England. After her death (November 1817) Stockmar became Leopold's secretary. He was active in the abortive negotiations (1829-30) to place Leopold on the throne of Greece and in promoting his successful candidature for the throne of Belgium (1830-31). Between 1831 and 1837 Stockmar acted mainly as Leopold's agent in England, where he helped to arrange the marriage (1836) between the widowed queen of Portugal and a Coburg prince.

With the accession of Queen Victoria to the throne of England in 1837, Stockmar's career entered a new phase. Leopold was Victoria's uncle, and planned a match between her and his nephew, Prince Albert of Saxe-Coburg-Gotha. Stockmar was employed to arrange the marriage (1840) and also to act as the queen's adviser. He now became attached rather to the English than to the Belgian court, and spent much of his time in England until 1857, when he retired finally to Germany. An ardent constitutionalist,

his advice to the queen and prince, though somewhat theoretical at times, contributed greatly in the early years of the reign to their determination to act with strict constitutionality. He attended the German diets of Frankfurt (1848) and Erfurt (1850) and favoured the progress of Prussian influence. He died at Coburg on July 9, 1863.

See *Memoirs of Baron Stockmar by His Son, Baron E. von Stockmar*, 2 vol. (1872); F. Eyck, *The Prince Consort* (1959). (D. E. D. B.)

**STOCKPORT**, a municipal (1835), county (1888) and parliamentary borough, partly in Lancashire and partly in Cheshire, Eng., 7 mi. SE of Manchester and 38½ mi. NE of Chester by road. Pop. (1961) 142,543. Area 13.2 sq.mi. (34 sq.km.). The ancient town stood on the southern slope of a narrow gorge where the Tame and Goyt rivers meet to form the Mersey, but the modern town has spread over the more level ground above. The town hall (1908) and the war memorial building opposite, which is the art gallery, stand on high ground and are built of Portland stone. Close by is Stockport College (1887–89). The chief of the 48 parks and open spaces are Vernon and Woodbank Memorial parks, which lie along the banks of the Goyt.

It is recorded that in the rebellion of 1172 the castle of Stockport (later demolished) was held against Henry II by his son, Geoffrey. Sir Robert de Stokeport granted a charter to the town about 1220, making it a free borough. In 1260 an annual fair and weekly market was granted, to be held on the site of the present marketplace. Stockport's grammar school was founded under the will of Sir Edmund Shaa, dated 1487. The 14th-century Church of St. Mary, reconstructed in the 19th century, was built on an earlier foundation. During the rebellion of 1745 the defeated forces of Prince Charles Edward descended on the town whose bridge had been demolished. Stockport figures largely in the industrial disturbances of the early 19th century. Trade unionism increased as cotton spinning and weaving were transformed from cottage to factory industries. By 1800 local weavers were persistently pressing Parliament for the regulation of their wages, and in 1808 demanded a fixed minimum price for their goods. Distress was increased by the bankruptcy of the employers, and by 1812 serious disorders broke out after which two weavers were hanged. Later, during the Chartist demonstrations, a procession marched on Stockport workhouse and took forcible possession. By 1822 cotton spinning was already Stockport's staple industry. Its importance as a hat-making town dates from the 18th century, although a document of 1585 indicates that even then hatting was a local industry. Today, engineering and the manufacture of chemicals have been added to these earlier industries.

**STOCKTON, FRANK (FRANCIS) RICHARD** (1834–1902), U.S. writer best known for *Rudder Grange* (1879) and the tantalizingly enigmatic story "The Lady or the Tiger?" (1882). Stockton was born in Philadelphia, Pa., April 5, 1834. Soon after graduating from high school he turned to journalism and contributed prolifically to periodicals. He was variously on the staffs of *Hearth and Home*, *Century Magazine* and *St. Nicholas Magazine*. After 1881 he devoted himself entirely to writing. He began with juveniles but after the success of the absurdly fanciful *Rudder Grange* wrote mainly for adults. Stockton's many novels and stories are typically full of farcical and fantastic incidents in a fairy-tale type of setting, although he also wrote conventional romances and adventure tales. Probably his best work in the romantic vein is *The Casting Away of Mrs. Lecks and Mrs. Aleskine* (1886). An admirer of Charles Dickens and Daniel Defoe, Stockton lacked their realism and moral earnestness, remaining aloof from contemporary concerns. His short stories are generally considered more successful than his novels. He died in Washington, D.C., April 20, 1902.

His work was collected in *The Novels and Stories of Frank R. Stockton* (23 vol., 1899–1904).

See Martin I. Griffin, Jr., *Frank R. Stockton; a Critical Biography* (1939).

**STOCKTON, ROBERT FIELD** (1795–1866), U.S. naval officer and public official who played an important role in events leading to the cession of California to the U.S. He was born in Princeton, N.J., Aug. 20, 1795, the grandson of Richard Stockton,

signer of the Declaration of Independence. Robert Stockton attended Princeton College for a time but in 1811 joined the Navy as a midshipman, shortly becoming attached to the frigate "President," under the command of Commodore John Rodgers. He served under Rodgers during the War of 1812 except for a brief period in Washington as aide to the secretary of the navy. At the conclusion of hostilities, Stockton was transferred to the Mediterranean, where he remained until 1821, participating (1815) in the war against the Barbary pirates. In 1821 he was placed in charge of the schooner "Alligator" and dispatched by the American Colonization Society to the west coast of Africa where he was able to obtain for the society the land which later became Liberia.

From 1828 to 1838 he lived in Princeton, devoting his attention to founding the New Jersey Colonization Society, of which he was first president, and to the construction of the Delaware and Raritan Canal, which owed its existence to him. He was responsible for obtaining the charter for the canal, for financing it with his own fortune, and for directing it as president during the last years of his life.

In 1838 he went to sea again, as commander of the flagship of the Mediterranean fleet. Pres. John Tyler asked him to join his cabinet as secretary of the navy, but Stockton refused, preferring to remain on active duty. With John Ericsson, later designer of the "Monitor," he drew up plans for the "Princeton," the first warship to be driven with a screw propeller, designing himself one of its guns, the largest in the U.S. fleet. On one occasion in 1844, while many distinguished visitors were on board the ship, Stockton's gun was fired and exploded, killing Secretary of State Abel P. Upshur and Secretary of the Navy Thomas W. Gilmer, and wounding numerous other passengers. Stockton was later absolved of all blame for the tragedy.

In 1845 he was chosen by Tyler to sail in the "Princeton" to Texas to deliver to the state government the annexation resolution of the U.S. government, and later in the same year he commanded the "Congress" on its voyage from Norfolk to the Pacific, where he had been ordered to take command of the fleet from Commodore John D. Sloat. War with Mexico having broken out while he was en route, Stockton immediately took command of U.S. land and sea forces, capturing Los Angeles, the Mexican stronghold, on Aug. 13, 1846.

Stockton set up a civil government, first naming himself as governor and later John C. Frémont (*q.v.*), who had been associated with him in the fighting. He subsequently fought and defeated the Mexicans at San Diego, San Gabriel, and La Mesa, after which Los Angeles, which the Mexicans had recaptured, again fell to the U.S. forces. The entire province of California was then ceded to the United States.

Stockton returned east in 1847 and resigned from the Navy three years later, on May 28, 1850. He served in the U.S. Senate from 1851 to 1853 and after 1853 was president of the Delaware and Raritan Canal Company. He died in Princeton on Oct. 7, 1866.

**STOCKTON**, a city of California, U.S., the seat of San Joaquin county, is on the San Joaquin river, 78 mi. (125 km.) E of San Francisco, approximately in the centre of the great central valley of California. Although situated 88 nautical miles (163 km.) from the sea, Stockton is a deepwater port and has become a major shipping point for the produce of the rich interior valley. The city had a population of 86,321 in 1960, and is the centre of a standard metropolitan statistical area (San Joaquin county) with a population of 249,989 in 1960. (For comparative population figures see table in CALIFORNIA: Population.)

Stockton traces its origins to 1843 when Capt. Charles Weber, a German immigrant, endeavoured to develop a grant of 48,747 ac. of rich valley land which he and a Mexican partner had secured from the government of Mexico. The first settlement, named Tuleburg after the characteristic tules, or bulrushes, of the region, failed to attract settlers until the discovery of gold in the famous Mother Lode of the Sierra Nevada in 1848. As its position at the head of navigation on the San Joaquin river made it the most advantageous supply point for the mines, the community grew rapidly. By the summer of 1849 the one permanent building of

1848 was surrounded by a tent city of about 1,000 inhabitants, the great majority of whom catered to the needs of the miners. During the height of the gold rush the little port of Tuleburg was visited by ships from Europe, South America and Asia, contemporary accounts telling of over 100 ships at anchor at one time.

In 1850 after fires virtually destroyed the original tent city and its ramshackle wooden successor, a planned community was begun by Captain Weber. Surveys were made, areas were set aside for schools, parks and churches, and the name was changed from Tuleburg to Stockton in honour of Commodore Robert Stockton, whom Weber had met during the course of the war with Mexico. By 1853 the city had reached a population of 5,000.

With the coming of the Central Pacific railroad in 1869 and the rapid settlement of the fertile interior valley, the economy of the area soon changed. Modern Stockton is a thriving trade centre but the wealth of the mines has long been superseded by the much greater wealth of the surrounding agricultural region. San Joaquin is a leading county in acreage value for vegetable crops and in acreage for Tokay grapes, asparagus and tomatoes. Agriculture is highly diversified, with approximately 100 different crops.

As large steamships supplanted the small ocean-going craft of the mining days, the natural channel of the San Joaquin river soon proved inadequate and the growing commerce of the area was lost to San Francisco. As early as 1871 plans had been made for the construction of a deepwater channel to serve the city, but despite a growing realization of its desirability, the financial burden of the undertaking was such that nothing could be done until 1930 when federal assistance was secured. Since its completion in 1933 the Port of Stockton has been greatly enlarged and improved and is now one of the largest general cargo terminals on the Pacific coast. The 32-ft. (9.8 m.) channel and a 33-ac. (13 ha.) turning basin make it possible for any ship in the U.S. merchant marine to dock at Stockton. Among the facilities for handling the diversified cargoes of the port are the 3,000,000-bu. capacity grain elevators and a fully automatic bulk ore terminal.

The mid-20th century was a period of increasing industrialization of the Stockton area, particularly in those industries relating to agriculture and food processing. Several military establishments are located nearby, notably the Sharpe general depot with its atomic food processing plant; and a naval supply annex and west coast communications centre.

Stockton is the home of the University of the Pacific, a Methodist liberal arts institution chartered in 1851. It includes a conservatory of music and schools of education, pharmacy and engineering; its facilities include, in addition to the Stockton campus, the Pacific Marine station at Dillon beach and the Pacific summer theatre at Columbia. The Stockton public-school system extends through junior college.

The city's program of cultural activities and recreational facilities includes the Haggin Art gallery and Pioneer Historical museum, a symphony orchestra, a successful civic theatre and an extensive park system. Stockton established a council-manager form of government in 1923. (M. H. Mo.)

**STOCKTON-ON-TEES**, a municipal and parliamentary borough and port in County Durham, England, on the left bank of the River Tees, 11½ mi. above its mouth and opposite Thornaby-on-Tees. Pop. (1961) 81,274. Area 8.5 sq.mi (22 sq.km.). Stockton's first market charter was granted in 1310 and it is still a big market centre for cattle and agricultural produce. Because of the presence of iron ore in the Cleveland Hills to the south (which has long been mined) and the Durham coalfield to the north, it grew into a big industrial centre and the leading Tees port until superseded by Middlesbrough. The port has 980 ft. (300 m.) of quays, a minimum depth of 12 ft. (3.6 m.) at low-water ordinary spring tide and 22½ ft. (6.9 m.) at high-water ordinary spring tide, and trades principally with Scandinavia and the Netherlands. The historic Stockton-Darlington Railway (opened 1825) was the first passenger-carrying railway. Stockton is interested in the development of diesel and electric locomotives. Many light industries are located in the town and partly within the borough is the Imperial Chemical Industries establishment at Billingham.

Stockton grew up around the manor house and later castle of the bishops of Durham, to whom the town belonged. It is said that King John granted a charter in 1214, but no trace of this remains. The borough is first mentioned in 1283. Since 1867 Stockton has sent one member to Parliament.

At Norton, 1 mi. N, St. Mary's Church, once collegiate, shows Saxon and Norman work and has remains of a three-decker pulpit.

**STOCKYARDS:** see SLAUGHTERHOUSE.

**STODDERT, BENJAMIN** (1751–1813), first U.S. secretary of the navy, was born in Charles County, Md. Following brief duty as a cavalry officer during the American Revolution, he served as secretary of the Board of War (1779–81) and later (1781–98) operated a highly successful shipping business in Georgetown, Md. During this time, Pres. George Washington commissioned Stoddert to assist in the land purchase negotiations involving the establishment of the District of Columbia.

In May 1798 Pres. John Adams named Stoddert secretary of the new navy department, which had been established in the face of a conflict with France. Under Stoddert's able direction the infant Navy grew from 3 frigates to more than 50 ships in 1801. He also authorized land purchases in six eastern seaboard locations for the construction of navy yards. Stoddert left office in 1801 as a result of the election defeat of President Adams and returned to his shipping business, which, however, never again prospered. He died at Bladensburg, Md., Dec. 18, 1813. (R. M. LA.)

**STOICHIOMETRY** (STOICHEIOMETRY), in chemistry, strictly denotes the determination of the proportions in which elements or compounds react with one another, and is occasionally extended to include the determination of atomic and molecular weights. The term, as used in analytical chemistry, refers to that branch of chemistry concerned with the weight relationships in gravimetric analysis, the volume relationships in volumetric analysis, and the calculations based on these relationships (see CHEMISTRY: Analytical Chemistry). The important stoichiometric relationships are expressed by the laws of constant composition, multiple proportions, and combining volumes. See also EQUIVALENT; REACTION KINETICS.

See E. T. Williams and R. C. Johnson, *Stoichiometry for Chemical Engineers* (1958); L. Mandelcorn (ed.), *Non-stoichiometric Compounds* (1963). (G. W. WD.)

**STOICS**, a school of philosophers founded at the close of the 4th century B.C. by Zeno of Citium and so called from the place where he delivered his lectures; viz., the Stoa or painted corridor on the north side of the market place at Athens. Stoicism, however, though it arose on Hellenic soil, is scarcely to be considered a product of purely Greek intellect, but rather as the first fruits of that interaction between west and east which followed the conquests of Alexander the Great. Zeno himself was of Phoenician descent; and hardly a single Stoic of eminence was a citizen of any city in the heart of Greece, unless we make Aristo of Chios, Cleanthes of Assus and Panaetius of Rhodes exceptions. Such lands as Cyprus, Cilicia and Syria, such cities as Citium, Soli, Heraclea in Pontus, Sidon, Carthage, Seleucia on the Tigris, Apamea by the Orontes, furnished the school with its scholars and presidents; Tarsus, Rhodes and Alexandria became famous as centres of its teaching. Moreover, Stoicism did not achieve its crowning triumph until it was brought to Rome, where the grave earnestness of the national character could appreciate its doctrine and where for two centuries or more it was the creed, if not the philosophy, of numbers of great men. It therefore stands in marked antithesis to the Academy, which was the typical school of Greece and of the Greek intellect.

The history of the Stoic school may conveniently be divided in the usual threefold manner: the old Stoa; the middle or transitional period (Diogenes of Seleucia, Boethus of Sidon, Panaetius, Poseidonius); and the Stoicism of the Roman empire.

#### THE OLD STOA

By the old Stoa is meant the period (c. 304–205 B.C.) down to the death of Chrysippus, the second founder; then was laid the foundation of theory, to which hardly anything of importance was afterward added. Confined almost to Athens, the school made its

way slowly among many rivals. Aristo of Chios and Herillus of Carthage, Zeno's heterodox pupils, Persaeus, his favourite disciple and housemate, the poet Aratus and Sphaerus, adviser of the Spartan king Cleomenes, are noteworthy minor names; but the chief interest centres about Zeno, Cleanthes and Chrysippus (qq.v.).

**Zeno.**—Zeno's residence at Athens fell at a time when the great movement which Socrates originated had spent itself in the second generation of his spiritual descendants. Neither Theophrastus at the Lyceum, nor Xenocrates and Polemo at the Academy, nor Stilpo, who was drawing crowds to hear him at Megara, could be said to have inherited much of the great reformer's intellectual vigour, to say nothing of his moral earnestness. Zeno visited all the schools in turn, but seems to have attached himself definitely to the Cynics; as a Cynic he composed at least one of his more important works, "the much admired *Republic*," which was a stumbling block to the school later on. In the Cynic school he found the practical spirit which he divined to be the great need of that troubled age. For a while his motto must have been "back to Socrates," or at least "back to Antisthenes." The Stoics always counted themselves among the Socratic schools and canonized Antisthenes and Diogenes; while reverence for Socrates was the tie which united to them such an accomplished writer upon lighter ethical topics as the versatile Persaeus, the protégé of Antigonos Gonatas. Zeno began, then, as a Cynic; and in the developed system we can point to a kernel of Cynic doctrine to which various philosophemes of other thinkers (more especially Heraclitus and Aristotle, but also Diogenes of Apollonia, the Pythagoreans and the medical school of Hippocrates in a lesser degree) were added. Thus, quite apart from the general similarity of their ethical doctrine, the Cynics were materialists; they were also nominalists, combating the Platonic theory of ideas; in their theory of knowledge they made use of "reason" (*logos*), which was also one of their leading ethical conceptions.

In all these particulars Zeno followed them, and the last is the more important, because, Chrysippus having adopted a new criterion of truth—a clear and distinct perception of sense—it is only from casual notices we learn that the elder Stoics had approximated to Cynicism in making right reason the standard. At the same time, it is certain that the main outlines of the characteristic physical doctrine, which is after all the foundation of their ethics and logic, were the work of Zeno. "Reason," which had been an ethical or psychological principle to the Cynics, received at his hands an extension throughout the natural world, in which Heraclitean influence is unmistakable.

**Cleanthes.**—If the recognition of physics and logic as two studies co-ordinate with ethics is sufficient to differentiate the mature Zeno from the Cynic author of the *Republic*, no less than from his own heterodox disciple Aristo, the elaboration on all sides of Stoic natural philosophy belongs to Cleanthes, who certainly was not the merely docile and receptive intelligence he is sometimes represented as being. He carried on and completed the assimilation of Heraclitean doctrine; but his own contributions were distinctive and original. He was able to transform Zeno's seeming dualism of God (or force) and formless matter into the lofty pantheism which breathes in every line of his famous hymn to Zeus. Heraclitus had indeed declared all to be in flux, but we ask in vain what is the cause for the unceasing process of his ever-living fire. It was left for Cleanthes to discover this motive cause in a conception familiar to Zeno, as to the Cynics before him, but restricted to the region of ethics—the conception of tension or effort. The soul of the sage, thought the Cynics, should be strained and braced for judgment and action; his first need is firmness and Socratic strength. But the mind is a corporeal thing. Then followed the flash of genius: this varying tension of the one substance everywhere present, a purely physical fact, accounts for the diverse destinies of all innumerable particular things; it is the veritable cause of the flux and process of the universe. Herein lies the key to the entire system of the Stoics, as Cleanthes' epoch-making discovery continually received fresh applications to physics, ethics and epistemology.

**Chrysippus.**—Zeno had caught the practical spirit of his age—

the desire for a popular philosophy to meet individual needs. But there was another tendency in post-Aristotelian thought—to lean upon authority and substitute learning for independent research—which grew stronger just in proportion as the fresh interest in the problems of the universe and the zeal for discovery declined. The representative of this tendency, Chrysippus, addressed himself to the congenial task of assimilating, developing, systematizing the doctrines bequeathed to him and, above all, securing them in their stereotyped and final form, not simply from the assaults of the past, but, as after a long and successful career of controversy and polemical authorship he fondly hoped, from all possible attack in the future. To his personal characteristics can be traced the hairsplitting and formal pedantry which ever afterward marked the activity of the school, the technical procedure of the "dialecticians," as they were called. He created their formal logic and contributed much that was of value to their psychology and epistemology; but he did not hesitate also to relabel and rearrange in every department; and he lavished care and attention on the logical terminology and on the refutation of fallacies, or, as his opponents declared, on the excogitation of fallacies which even he could not refute.

**Stoic Conception of Philosophy.**—What is philosophy? No idle gratification of curiosity, no theory divorced from practice, no pursuit of science for its own sake, but knowledge realized in virtuous action, the learning of virtue by exercise and effort and training. So absolutely is the "rare and priceless wisdom" identical with virtue itself that the three main divisions of philosophy current at the time and accepted by Zeno—logic, physics and ethics—are defined as the most generic or comprehensive virtues. Accordingly Aristo rejected two of these parts of philosophy as useless and out of reach—a divergence which excluded him from the school, but strictly consistent with his view that ethics alone is scientific knowledge. Of the three divisions logic is the least important; ethics is the outcome of the whole and historically the all-important vital element; but the foundations of the whole system are best discerned in the science of nature, which deals pre-eminently with the macrocosm and the microcosm, the universe and man, including natural theology and anthropology or psychology, the latter forming the direct introduction to ethics.

**Physics.**—The materialism of the Stoics was not open to some of the objections that had been leveled at the doctrine of the Cynics and of the atomists. In Plato's *Sophist* (246 C *et seq.*), the Eleatic stranger had argued as follows against those "who drag everything down to the corporeal": "They admit the existence of an animate body. Is soul then something existent? Yes. And the qualities of soul, as justice and wisdom—are they visible and tangible? No. Do they then exist? They are in a dilemma." Now this reasoning is ineffective against the Stoics, who take boldly the one horn of the dilemma. That qualities of bodies (and therefore of the corporeal soul) exist they do not deny; but they assert most uncompromisingly that they are one and all (wisdom, justice, etc.) corporeal. And they strengthen their position by taking Plato's own definition (247 D), namely "being is that which has the power to act or be acted upon," and turning it against him. For this is only true of body; action, except by contact, is inconceivable; and they reduce every form of causation to the efficient cause, which implies the communication of motion from one body to another. Again and again, therefore, only body exists. The most real realities to Plato and to Aristotle had been thought and the objects of thought, *noûs* and *noêta*, whether abstracted from sensibles or inherent in "matter," as the incognizable basis of all concrete existence. But this was too great an effort to last long. Such spiritualistic theories were nowhere really maintained after Aristotle and outside the circle of his immediate followers. The reaction came and left nothing of it all; for five centuries the dominant tone of the older and the newer schools alike was frankly materialistic. "If," says Aristotle, "there is no other substance but the organic substances of nature, physics will be the highest of the sciences," a conclusion which passed for axiomatic until the rise of Neoplatonism. The analogues therefore of metaphysical problems must be sought in physics; particularly that problem of the causes of things for which the Platonic idea and the Peripatetic

"constitutive form" had been, each in its turn, received solutions.

Yet the doctrine that all existence is confined within the limits of the sensible universe—that there is no being save corporeal being or body—does not suffice to characterize the Stoic system; it is no less a doctrine of the Epicureans. It is the idea of tension or tonic as the essential attribute of body, in contradistinction to passive inert matter, which is distinctively Stoic. The Epicureans leave unexplained the primary constitution and first movements of their atoms or elemental solids; chance or declination may account for them. Now, to the Stoics nothing passes unexplained; there is a reason (*logos*) for everything in nature. Everything which exists is at once capable of acting and being acted upon. In everything that exists, therefore, even the smallest particle, there are these two principles. By virtue of the passive principle the thing is susceptible of motion and modification; it is matter which determines substance. The active principle makes the matter a given determinate thing, characterizing and qualifying it, whence it is termed quality. For all that is or happens there is an immediate cause or antecedent; and as "cause" means "cause of motion," and only body can act upon body, it follows that this antecedent cause is itself as truly corporeal as the matter upon which it acts. Thus we are led to regard the active principle "force" as everywhere coextensive with "matter," as pervading and permeating it and together with it occupying and filling space. This is that famous doctrine of universal permeation, by which the axiom that two bodies cannot occupy the same space is practically denied. Thus that harmony of separate doctrines which contributes to the impressive simplicity of the Stoic physics is only attained at the cost of offending healthy common sense, for body itself is robbed of a characteristic attribute. A thing is no longer, as Plato once thought, hot or hard or bright by partaking in abstract heat or hardness or brightness, but by containing within its own substance the material of these qualities, conceived as air currents in various degrees of tension. We hear, too, of corporeal days and years, of corporeal virtues and of actions (like walking) which are bodies. Obviously, again, the Stoic quality corresponds to Aristotle's essential form; in both systems the active principle, "the cause of all that matter becomes," is that which accounts for the existence of a given concrete thing. Only here, instead of assuming something immaterial (and therefore unverifiable), we fall back upon a current of air or gas, *pneuma*; the essential reason of the thing is itself material, standing to it in the relation of a gaseous to a solid body. Here, too, the reason of things—that which accounts for them—is no longer some external end to which they are tending; it is something acting within them, germinating and developing as from a seed in the heart of each separate thing that exists. By its prompting the thing grows, develops and decays, while this "germinal reason," the element of quality in the thing, remains constant through all its changes.

**Psychology and Theory of Knowledge.**—In the rational creatures—man and the gods—*pneuma* is manifested in a high degree of purity and intensity as an emanation from the world soul, itself an emanation from the primary substance of purest ether—a spark of the celestial fire, or, more accurately, fiery breath, which is a mean between fire and air, characterized by vital warmth more than by dryness. The physical basis of Stoic psychology deserves the closest attention. On the one hand, soul is corporeal, else it would have no real existence, would be incapable of extension in three dimensions (and therefore of equable diffusion all over the body), incapable of holding the body together, as the Stoics contended that it does, herein presenting a sharp contrast to the Epicurean tenet that it is the body which confines and shelters the light vagrant atoms of soul. On the other hand, this corporeal thing is veritably and identically reason, mind and ruling principle; in virtue of its divine origin Cleanthes can say to Zeus "We too are thy offspring," and Seneca can calmly insist that, if man and God are not on perfect equality, the superiority rests rather on our side. What God is for the world, that the soul is for man. The cosmos must be conceived as a single whole, its variety being referred to varying stages of condensation in *pneuma*. So, too, the human soul must possess absolute simplicity, its varying functions being conditioned by the degrees or species of its tension. It fol-

lows that of "parts" of the soul, as previous thinkers imagined, there can be no question; all that can consistently be maintained is that from the centre of the body—the heart—seven distinct air currents are discharged to various organs, which are so many modes of the one soul's activity. The ethical consequences of this position will be seen at a later stage.

With this psychology is intimately connected the Stoic theory of knowledge. From the unity of soul it follows that all psychical processes—sensation, assent, impulse—proceed from reason, the ruling part; that is to say, there is no strife or division: the one rational soul alone has sensations, assents to judgments, is impelled toward objects of desire just as much as it thinks or reasons.

**Formal Logic.**—The dynamic materialism of the Stoics led them to develop a nominalist two-valued logic of propositions which was of considerable importance and differed radically from the Aristotelian logic of terms. Admitting the reality only of the individual, subject to a series of changes, the Stoics made central the singular proposition and interpreted the relation between subject and predicate, not as that of inheritance or inclusion, but as that of concomitance or sequence, thus moving away from the Aristotelian notion of essence toward the concept of law. A detailed account of Stoic logic, both as distinct from the syllogistic of Aristotle and as related to the logic of the Megarian school of philosophy, is given in the article LOGIC, HISTORY OF, where its technical aspects are discussed at length. It may be claimed that the Stoics, insisting on the logical primacy of words, not meanings, were pioneers of formalistic logic.

**Cosmopolitanism.**—In their view of man's social relations the Stoics were greatly in advance of preceding schools. We saw that virtue is a law which governs the universe: that which reason and God ordain must be accepted as binding upon the particle of reason which is in each one of us. Human law comes into existence when men recognize this obligation; justice is therefore natural and not something merely conventional. The opposite tendencies, to allow to the individual responsibility and freedom and to demand of him obedience to law, are both features of the system; but in virtue even of the freedom which belongs to him *qua* rational, he must recognize the society of rational beings of which he is a member and subordinate his own ends to the ends and needs of this society. Those who own one law are citizens of one state, the city of Zeus, in which men and gods have their dwelling. In that city all is ordained by reason working intelligently, and the members exist for the sake of one another; there is an intimate connection between them which makes all the wise and virtuous friends, even if personally unknown, and leads them to contribute to one another's good. Their intercourse should find expression in justice, in friendship, in family and political life. But practically the Stoic philosopher always had some good excuse for withdrawing from the narrow political life of the city in which he found himself. The circumstances of the time, such as the decay of Greek city life, the foundation of large territorial states under absolute Greek rulers and afterward the rise of the world empire of Rome, aided in developing the leading idea of Zeno's *Republic*. There he had anticipated a state without family life, without law courts or coins, without schools or temples, in which all differences of nationality would be merged in the common brotherhood of man. This cosmopolitan citizenship remained all through a distinctive Stoic dogma; when first announced it must have had a powerful influence upon the minds of men, diverting them from the many distractions of almost parochial politics to a boundless vista.

**Religion.**—The religious problem had peculiar interest for the school which discerned God everywhere as the ruler and upholder, and at the same time the law, of the world that He had evolved from Himself. The physical groundwork lends a religious sanction to all moral duties, and Cleanthes' hymn is evidence how far a system of natural religion could go in providing satisfaction for the cravings of the religious temper:

Most glorious of immortals, O Zeus of many names, almighty and everlasting, sovereign of nature, directing all in accordance with law, thee it is fitting that all mortals should address. . . . Thee all this universe, as it rolls circling round the earth, obeys wheresoever thou dost

guide, and gladly owns thy sway. Such a minister thou loddest in thy invincible hands—the two-edged, fiery, everliving thunderbolt, under whose stroke all nature shudders. No work upon earth is wrought apart from thee, lord, nor through the divine ethereal sphere, nor upon the sea; save only whatsoever deeds wicked men do in their own foolishness. Nay, thou knowest how to make even the rough smooth, and to bring order out of disorder; and things not friendly are friendly in thy sight. For so hast thou fitted all things together, the good with the evil, that there might be one eternal law over all. . . . Deliver men from fell ignorance. Banish it, rather, from their soul, and grant them to obtain wisdom, whereon relying thou rulest all things with justice.

To the orthodox theology of Greece and Rome the system stood in a twofold relation, as criticism and as rationalism. That the popular religion was open to criticism hardly needed to be pointed out: the forms of worship could be described as trivial or as mischievous, the myths as immoral. But Zeno declared images, shrines, temples, sacrifices, prayers and worship to be of no avail. A really acceptable prayer, he taught, can only have reference to a virtuous and devout mind: God is best worshiped in the shrine of the heart by the desire to know and obey Him.

At the same time the Stoics felt at liberty to defend and uphold the truth in polytheism. Not only is the primitive substance God, the one supreme being, but divinity must be ascribed to His manifestations—to the heavenly bodies, which are conceived, like Plato's created gods, as the highest of rational beings, to the forces of nature, even to deified men; and thus the world was peopled with divine agencies. Moreover, the myths were rationalized and allegorized. The search for a hidden meaning besides the literal one had been begun by Democritus, Empedocles, the Sophists and the Cynics. It remained for Zeno to carry this to a much greater extent and to seek out or invent "natural principles" (*logoi physikoi*) and moral ideas in all the legends and in the poetry of Homer and Hesiod.

#### THE MIDDLE STOA AND ROME

The principal representatives of the middle period of Stoicism were Panaetius (q.v.) and Poseidonius (q.v.; Posidonius) and the introduction of Stoicism to Rome, which took place during this period, was an event of great moment both in the history of the school and in that of the city. After the first sharp collision with the jealousy of the national authorities it found a ready acceptance and made rapid progress among the noblest families. It has been well said that the old heroes of the republic were unconscious Stoics, fitted by their narrowness, their stern simplicity and devotion to duty for the earnestness of the new doctrine. In Greece its insensibility to art and the cultivation of life was a fatal defect; not so with the shrewd men of the world, desirous of qualifying as advocates or jurists. It supplied them with an incentive to scientific research in archaeology and grammar; it penetrated jurisprudence until the belief in the ultimate identity of the *jus gentium* (see ROMAN LAW) with the law of nature modified the praetor's edicts for centuries. Even to the prosaic religion of old Rome it became in some sort a support. Q. Mucius Scaevola, following Panaetius, explained that statesmen had established this public institution in the service of order midway between superstition and the barren truths of philosophy. Soon the influence of the pupils reacted upon the doctrines taught. Of speculative interest the ordinary Roman had little; for abstract discussion and controversy he cared nothing. All had to be simplified and disengaged from technical subtleties. To attract his Roman pupils Panaetius would naturally choose simple topics susceptible of rhetorical treatment or of application to individual details. He was the representative, not merely of Stoicism, but of Greece and Greek literature and would feel pride in introducing its greatest masterpieces. Among all that he studied, he valued most the writings of Plato. He admired the classic style, the exquisite purity of language, the flights of imagination, but he admired above all the philosophy. He marks a reaction of the Hellenic spirit against the austerity of the first Stoics.

His pupil, Poseidonius, a man of great natural austerity, carried still further the eclectic tendencies evident in Panaetius. His wide learning in history and in natural science and his moral seriousness appealed to the cultivated Roman mind. His religious

and psychological teaching, deeply influenced by Plato, prepared the way for the late Stoa with its dominantly religious character. The thought of such men as Cicero, Seneca, Manilius and Plutarch is greatly indebted to him.

No account of Stoicism in Rome can be complete which fails to mention the part played by Cicero who, though not a professional Stoic, was sympathetic to much in Stoicism. His philosophical writings contain exposition and discussion of Stoic doctrine in all branches of philosophy, and without them our knowledge of Stoicism would be much less adequate than it is.

#### THE LATER STOICS

The writings of the later Stoics have come down to us, if not entire, in great part, so that L. Annaeus Seneca, L. Annaeus Cornutus, Aulus Persius, Lucan, Epictetus and Marcus Aurelius Antoninus (q.v.) are known at first hand. They do not pretend to give a scientific exposition of doctrine, and may therefore be dismissed somewhat briefly. We learn much more about the Stoic system from the scanty fragments of the first founders, or even from the epitomes of Diogenes Laërtius and Stobaeus, than from these writers. They testify to the restriction of philosophy to the practical side and to the increasing tendency, ever since Panaetius, toward a relaxation of the rigorous ethical doctrine and an approximation to the form of religious conviction.

This finds most marked expression in the doctrines of submission to Providence and universal philanthropy. Only in this way could they hold their ground, however insecurely, in face of the revival of religion inaugurated by the emperor Augustus. In passing to Rome, Stoicism had quitted the school for actual life, and the fall of the republic was indeed a gain, for it released much intellectual activity from civic duties. The life and death of Cato, moreover, fired the imagination of a degenerate age in which he stood out both as a Roman and a Stoic. To a long line of illustrious successors, including men like Thrasya Paetus and Helvidius Priscus, Cato bequeathed his resolute opposition to the dominant power of the times; unsympathetic, unpractical, fearless in demeanour, they were a standing reproach to the corruption and tyranny of their age. In the early years of the empire, however, when Augustus had restored order, philosophy became bolder and addressed every class in society, public and spiritual direction being the two forms in which it now showed activity. Books of direction were written in Greek by Q. Sextius (as afterward in Latin by Seneca) almost the only Roman who had the ambition to found a sect, though in fact he mainly followed Stoicism. His contemporary Papirius Fabianus was the popular lecturer of that day, producing a powerful effect by his denunciations of the manners of the time. Under Lucius Sotion and Attalus were attended by crowds of hearers.

Seneca.—Seneca is the most prominent leader in the development of which Roman Stoicism now took. His penetrating intellect mastered the subtleties of the system of Chrysippus, but he seldom appears in his works, at least without apology. Fundamentally we meet there with the doctrines of pneuma and the union of the corporeal nature of the virtues and the affective much more to the same effect. But his attention is directed to physics chiefly as a means of elevating the mind and as a known the wisdom of Providence. Chrysippus had argued that natural evil was a thing indifferent—that even moral was required in the divine economy as a foil to set off good prosperity of the wicked and the calamity of the just he explained in various ways: sometimes he alleged the forgetfulness of higher powers; sometimes he fell back upon the necessity of contrasts and grotesque passages in the comedy of human life. Seneca gives the true Stoic answer in his treatise *On Providence*: the wise man cannot really meet with misfortune; all calamity is a divine instrument of training, designed to test his powers and teach the world the indifference of external conditions. In the soul Seneca recognizes an effluence of the spirit, a god in the human frame; in virtue of this he possesses the essential dignity and internal freedom of man in every being. Yet, in striking contrast with this orthodox tenet, is a vivid concept of the weakness and misery of men, the base

but also to the solution of practical problems, such as the flow of water in rivers and channels and the skin resistance of ships. (See also CENTRIFUGE: *Effect on Liquids*; ELECTRON: *Oil Drop Measurement of e.*)

His best-known researches are perhaps those on the undulatory theory of light. His first papers on the aberration of light appeared in 1845 and 1846 and were followed in 1848 by one on the theory of certain bands seen in the spectrum. In 1849 his paper on the dynamic theory of diffraction showed that the plane of polarization must be perpendicular to the direction of vibration. Two years later he discussed the colours of thick plates; and in 1852 in his famous paper on the change of refrangibility of light, he described the phenomenon of fluorescence, as exhibited by fluor-spar and uranium glass, materials which he viewed as having the power to convert invisible ultraviolet rays into rays of wavelengths which are visible (see LUMINESCENCE: *Early History: Fluorescence and Luminescence*). A mechanical model illustrating the dynamic principle of Stokes's explanation was shown in 1883, during a lecture at the Royal Institution by Lord Kelvin, who said he had heard an account of it from Stokes many years before and had repeatedly but vainly begged him to publish it. In the same year, 1852, there appeared the paper on the composition and resolution of streams of polarized light from different sources, and in 1853 an investigation of the metallic reflection exhibited by certain nonmetallic substances. About 1860 he was engaged in an inquiry on the intensity of light reflected from, or transmitted through, a pile of plates; and in 1862 he prepared for the British Association a valuable report on double refraction, which marks a period in the history of the subject in England. A paper on the long spectrum of the electric light bears the same date and was followed by an inquiry into the absorption spectrum of blood. (See also LIGHT: *Types of Polarized Light*.)

The discrimination of organic bodies by their optical properties was treated in 1864; and later, in conjunction with the Rev. W. Vernon Harcourt, he investigated the relation between the chemical constitution and the optical properties of various glasses, with reference to the conditions of transparency and the improvement of achromatic telescopes. A still later paper connected with the construction of optical instruments discussed the theoretical limits to the aperture of microscope objectives. In other departments of physics may be mentioned his paper on the conduction of heat in crystals (1851) and his inquiries in connection with the radiometer; his explanation of the light border frequently noticed in photographs just outside the outline of a dark body seen against the sky (1883); and still later his theory of Roentgen or X rays, which he suggested might be transverse waves traveling as innumerable solitary waves, not in regular trains. Two long papers published in 1849—one on attractions and Clairaut's theorem and the other on the variation of gravity at the surface of the earth—also demand notice, as do his mathematical memoirs on the critical values of the sums of periodic series (1847) and on the numerical calculation of a class of definite integrals and infinite series (1850) and his valuable discussion of a differential equation relating to the strains, stresses and other factors involved in the breaking of railway bridges (1849). (See also GEODESY: *Methods and Achievements of Physical Geodesy*.)

Many of his discoveries were only touched upon in lectures. An instance is his work in the theory of spectrum analysis. Some of Stokes's friends and pupils claimed that he had anticipated the work of G. R. Kirchhoff, but Stokes maintained that he had failed to see an essential step in the argument and disclaimed priority. As Lucasian professor, Stokes announced that he wished to help any member of the university in his mathematical studies, and pupils were glad to consult him, even after they had become colleagues. During the 30 years of his secretaryship to the Royal Society he advanced the cause of mathematical and physical science not only by his own investigations but by suggesting problems for inquiry and encouraging men to attack them.

He received the Rumford medal in 1852 and the Copley medal in 1893. His numerous other honours included the Prussian order of merit.

Sir George Stokes's mathematical and physical papers were pub-

lished in a collected form in five volumes; the first three (1880, 1883 and 1901) under his own editorship and the two last (1904 and 1905) under that of Sir Joseph Larmor, who also selected and arranged the *Memoir and Scientific Correspondence* of Stokes published at Cambridge in 1907. Stokes was the author of *Light* (1884-87) and *Natural Theology* (1891).

**STOKES, SIR (FREDERICK) WILFRID SCOTT** (1860-1927), English engineer and inventor who gained distinction in many notable engineering achievements, including the Manchester Ship Canal and irrigation works in India, Egypt, and the Sudan, was born in Liverpool on April 9, 1860. After several years in railway work, in 1885 he joined the engineering firm Ransomes and Rapier of Ipswich, Suffolk, later becoming managing director and chairman. His inventions, for which about 50 patents were granted, included improvements in breakdown cranes; railway, hydraulic, refrigerating, and cement-making machinery; ordnance; and projectiles. Stokes was responsible for the design of the sluice and lock gates of the Aswan Dam on the Nile (1901) and the Sennar Dam on the Blue Nile. He invented the Stokes trench mortar and ammunition (1914) and was influential in developing effective anti-aircraft shells. Stokes was knighted in 1917 and died at Ruthin, Denbighshire, Wales, on Feb. 7, 1927.

**STOKESAY**, a fortified manor house in Shropshire, Eng., 6½ mi. (10.5 km.) NW of Ludlow. Stokesay Castle is one of the most remarkable moated manor houses surviving in England. It was built in 1240 by John de Verdon with banqueting hall, north tower, and solar (paneled in the 17th century). The south tower was added in 1291 when the Ludlows bought Stokesay and fortified it. The 16th-century half-timbered gatehouse replaces the old entrance tower. From 1620 to 1869 (when it was thoroughly repaired) Stokesay belonged to the lords Craven.

**STOLBERG, FRIEDRICH LEOPOLD**, GRAF ZU STOLBERG (1750-1819), German poet, known for his ballads, and of literary importance for his close association with the Göttingen *Hain* (see GERMAN LITERATURE: *The Age of Goethe*), was born at Bramstedt, Holstein, on Nov. 7, 1750. He studied law at Halle (1770) and Göttingen (1772). Enthusiasm for Klopstock, Greek literature, and nature led him to join the Göttingen *Hain*; his friendship with Goethe began when he and his brother, Christian (1748-1821), also a poet, arrived in Frankfurt in May 1775, dressed in "Werther costume" (blue coat, yellow waistcoat, and breeches), and invited Goethe to accompany them on a "sentimental" journey to Switzerland, of which there are accounts in Stolberg's *Tagebüchern* and Goethe's *Dichtung und Wahrheit*. During 1777-1800 he was mainly in the diplomatic service of the prince-bishop of Lübeck. In 1791 he traveled through Germany, Switzerland, and Italy before becoming president of the episcopal court at Eutin. In 1800 he retired to Münster, Westphalia; and in 1816 to his estate at Sondermühlen, near Osnabrück, where he died on Dec. 5, 1819.

Like other members of the Göttingen *Hain*, Stolberg wrote patriotic revolutionary odes extolling freedom and denouncing tyranny. His ballads form a link with the ballads of chivalry of the German Romantics, especially of the Swabian school. He also wrote satires and dramas, and excelled as a translator. His translations of Aeschylus (1782-83; published, after stylistic revision, in 1802), the Iliad (1778), and Plato (1796-97) helped to spread understanding of the Greek spirit in Germany. Schiller used the Aeschylus translations when working on the chorus in his *Die Braut von Messina*.

In 1800 Stolberg joined the Roman Catholic Church. This conversion, severely attacked by his former friend and benefactor J. H. Voss, led to his rejection of the spirit of the Enlightenment, of 18th-century Pietism, of the French Revolution, and, as he became more extreme, even of Schiller's attitude to the Greek gods. These cumulative rejections may be said to have initiated the trend toward Catholicism among the German Romantics.

**STOLBERG**, an industrial town of West Germany in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany, lies 7 mi. (11 km.) E of Aachen. Pop. (1961) 37,462. The castle, founded in the 12th century, has been restored. The town is first mentioned in 1118 and was chartered in 1856. Its economic development began in the 17th century with the rise of the brass industry. Metal industries now include brass, copper, lead, zinc, tin, and iron. Glass, cables, rubber, textiles, lime, chemicals, soap, pharmaceutical goods, and furniture are produced, and there are spinning, brewing, and building construction enterprises.

**STOLE**, a liturgical vestment of the Roman Catholic Church, peculiar to the higher orders; i.e., deacons, priests and bishops. Its equivalents in the Eastern Churches are the epitachelion of priests and the oration of deacons. See **VESTMENTS**, **ECCESTASTICAL**.

**STOLYPIN, PETR ARKADIEVICH** (1862–1911), Russian statesman, the sponsor of the last considerable reform envisaged before World War I and the Revolution. He was born at Dresden, in Saxony, on April 14, 1862, of an old noble family of Russian landowners, and was educated in St. Petersburg. Appointed governor of Grodno province in 1902, he was transferred to Saratov province in 1903. There in 1905 he attracted notice by his self-control and determination in quelling peasant disturbances. In May 1906 he was appointed minister of the interior, an office which he retained on becoming premier in July.

Stolypin set out to consolidate the new semiconstitutional regime by suppressing revolutionary violence and by improving the juridical and economic position of the peasants. His reform, inaugurated by a decree of Nov. 22 (new style; 9, old style), 1906, and given final legislative shape in 1910 and 1911, involved a radical transformation of Russia's agrarian structure. Peasants were encouraged to leave the commune and to secure their holdings as individual property; where possible, they were to consolidate their scattered strips of land into enclosed farms. This was designed to promote technical progress and to create a class of prosperous farmers who would constitute a bulwark of conservatism in the Russian countryside. The reform also comprised measures to expand credit facilities, to promote internal colonization (particularly in Siberia), to improve the machinery of local self-government, and to develop the educational system.

Stolypin sought the collaboration of the liberal opposition in realizing his program, but insisted on their accepting his terms. When the second Duma (*q.v.*) refused to endorse his policies it was dissolved in June 1907 and a new electoral law was promulgated without its consent, restricting the franchise. Stolypin was ready to disregard constitutional legality if he believed the government's vital interests to be at stake.

In the third Duma, Stolypin at first relied for support on the moderate (conservative) Octobrists, but a breach developed over his ruthless policy toward the Finns and other national minorities. He was a convinced Russian nationalist, and his zeal in this cause led in March 1911 to a constitutional crisis. He prevailed on the emperor Nicholas II to suspend both legislative chambers while he promulgated, as an emergency measure, a decree establishing *zemstva* (local assemblies) in the western provinces of the empire. This antagonized public opinion and also played into the hands of the right-wing politicians who were intriguing against him with the emperor. Stolypin was now virtually isolated. On Sept. 14 (N.S.), 1911, at a Kiev theatre in the emperor's presence, he received bullet wounds from which he died four days later. His assassin was a former terrorist and police agent, Dmitri (Mordka) Bogrov. Mysterious features of the affair suggested that his death was not unwelcome to his highly placed enemies.

See Alexandra Stolypine, *L'Homme du dernier Tsar* (1931); V. Bogrov, *Dmitri Bogrov i ubiystvo Stolypina* (1931). (J. L. H. K.)

**STOMACH**, the baglike digestive organ which in man lies in

the upper left part of the abdomen between the esophagus and the duodenum. For anatomical details see **GASTROINTESTINAL TRACT**. For the functions of the stomach see **DIGESTION**. For the diseases of the stomach in general see **GASTROINTESTINAL TRACT, DISEASES OF**; for particular ailments see **GASTRIC AND DUODENAL ULCER**; **GASTRITIS**; **INDIGESTION**. See also references under "Stomach" in the Index.

**STOMACH, SURGERY OF**. The first successful major operations upon the stomach were performed by Theodor Billroth (1829–94) of Vienna. His procedures included two separate approaches for excisional therapy of cancer of the stomach: (1) partial removal of the stomach with reestablishment of direct continuity between the cut end of the stomach and the duodenum, and (2) partial removal of the stomach with construction of an indirect continuity between the stomach and the jejunum. Surgery of the stomach was not possible before Billroth chiefly because the required opening of the abdominal cavity (laparotomy; *q.v.*) was not feasible until general anesthesia and antisepsis were developed.

Stomach operations are performed mainly for (1) cancer of the stomach, (2) ulcer of the stomach or duodenum, and (3) hypertrophic pyloric stenosis.

**Cancer of the Stomach**.—Surgical treatment for this condition involves a subtotal or total removal of the stomach, reconstruction of the continuity of the intestinal tract so that food can again pass into the small intestine, and removal of the greater omentum, spleen, and surrounding lymph node areas. If there are obvious extensions into other organs that can be sacrificed (colon, left lobe of liver, pancreas, etc.) these are removed as well. When all the apparently cancerous tissue is removed, about one-third of the patients are still alive after five years. Surgery for cancer of the stomach has about a 10% mortality; without such treatment, fewer than 5% of the patients survive for three years.

**Ulcer of the Stomach or Duodenum**.—The aim of surgery for gastric or duodenal ulcers is different from that for cancer. The aim is not primarily to remove the ulcer but instead to reduce the secretion of acid by the parietal cells in the central portion (corpus) of the stomach so that the ulcer will heal. This may be accomplished by removing most of the corpus (i.e., by subtotal gastric resection) or by cutting down on the strongest stimulators of acid secretion. These stimulators include nervous stimuli transmitted by the two abdominal branches of the vagus nerve, which may be cut bilaterally at the level of the diaphragm or selectively to the stomach only, and hormonal stimuli that arise from the lower portion (antrum) of the stomach; the hormonal stimuli may be eliminated by removing the antrum. Surgery for ulcer, therefore, usually involves one or more of the following procedures: cutting the vagal nerves, subtotal resection of the corpus, removal of the antrum, and often a sidetracking procedure to permit more easy exit of food from the stomach. Surgery for ulcer has about a 1–2% mortality and gives good results in 90% of cases.

While these principles apply to ulcers of both the stomach and duodenum, treatment of duodenal ulcer differs in that it is directed at the adjoining organ, the stomach, where the acid is secreted, rather than at the ulcerated duodenum itself. (See also **GASTRIC AND DUODENAL ULCER**.)

**Hypertrophic Pyloric Stenosis**.—This condition represents a hypertrophy, or overgrowth, of the muscle that surrounds the pylorus (outlet) of the stomach. Its highest incidence is in first-born males, in whom it occurs at a rate of 1 in 300 at about the third week of life. If the condition is not treated surgically, the stomach contents cannot go through the narrowed ring and the mortality is 50–75%. The preferred method of surgery involves cutting the thickened muscular ring without cutting into the interior of the pyloric canal. This operation has about a 0.5% mortality and gives good results in 99% of cases.

**STONE, BARTON WARREN** (1772-1844), U.S. religious leader, one of the founders of the Disciples of Christ (*q.v.*), was born in Maryland on Dec. 24, 1772, and educated in academies of the Piedmont. Stone was ordained to the Presbyterian ministry in 1798, though he was more Arminian than Calvinist in his views and stressed primitive Christian thought and practice. He was preacher at Cane Ridge Church, near Paris, Ky., when it became the centre of the Great Revival (1801-03) and an immense camp meeting with many preachers participating (see *REVIVALISM*). In 1803 Stone and five colleagues left the Synod of Kentucky and formed the Springfield Presbytery. In 1804, after biblical study, they signed "The Last Will and Testament of the Springfield Presbytery," dissolving that body that it might "sink into union with the Body of Christ at large." This act on behalf of Christian unity furthered among churches of the Carolinas and Kentucky a movement toward congregational polity and the use of the name "Christian" only. Stone gradually became the leader of this movement west of the Allegheny Mountains, establishing the *Christian Messenger* (1826-37; 1839-45) to propagate his liberal views and to urge Christian unity. Stone's acquaintance with Alexander Campbell (*q.v.*) began in the 1820s, and in 1832 followers of the two men joined to form the Disciples of Christ or Christian Church. Stone's eagerness for the union is credited as the decisive factor in its achievement, but leadership fell upon the younger Campbell. Stone, always a frontier spirit, moved west, settling in Illinois. He died in Missouri on Nov. 9, 1844, and is buried at Cane Ridge, where his log church is enshrined.

**STONE, EDWARD JAMES** (1831-1897), British astronomer, who improved the fundamental constants of astronomy, was born in London on Feb. 28, 1831. Educated at King's College, London, and Queen's College, Cambridge, in 1860 he became chief assistant to the astronomer royal at the Royal Observatory, Greenwich. Stone deduced the solar parallax, first from observations of Mars, obtaining 8.932" and 8.945", and then from the transit of Venus in 1869, which yielded 8.91". He received the Gold Medal of the Royal Astronomical Society in 1869 and was appointed astronomer at the Cape Observatory, South Africa, in 1870. He was appointed Radcliffe observer at Oxford in 1878 and served as president of the Royal Astronomical Society from 1882 to 1884. Stone died at Oxford on May 9, 1897. (O. J. E.)

**STONE, HARLAN FISKE** (1872-1946), 12th chief justice of the United States, participated in making more of his dissenting positions become law than any other justice in history. He was born in Chesterfield, N.H., on Oct. 11, 1872, and died in Washington, D.C., on April 22, 1946. After graduating from Amherst College in 1894 and receiving his law degree from Columbia University Law School in 1898, he taught law there and practised in New York from 1899 until 1924. He was dean of Columbia Law School from 1910 until 1923. In 1924 Pres. Calvin Coolidge appointed him attorney general of the United States, and in 1925 associate justice of the U.S. Supreme Court. In 1941, Pres. Franklin D. Roosevelt appointed him chief justice.

His tenure on the Supreme Court was marked by three rather distinct areas of constitutional debate in addition to the

perennial constitutional controversy concerning the authority of one state to regulate or tax persons or institutions connected with several states. During the first half of his tenure the great controversy involved the power of a state to make changes in its economic or legal order by regulations, prohibitions, or taxes. During most of this period he was associated with Justices Oliver Wendell Holmes and Louis Brandeis, and part of the time with Justice Benjamin Cardozo as one of three "great dissenters." A second period of his judicial career involved a controversy over the power of the national government to make changes in the economic or legal order of the nation. This was the period of the New Deal legislation. During his chief justiceship the great debate concerned the power of the popular majority to control matters touching affairs of conscience and expression.

In each of these areas, first as a dissenter and later writing for the majority, Stone made contributions to constitutional jurisprudence. The culmination of his views on the power of a state to regulate interstate commerce came in an opinion shortly before his death, *Southern Pacific Company v. Arizona*, 325 U.S. 761 (1945), in which he restated the historic position of the Supreme Court that the commerce clause of the Constitution gave the court power to invalidate local legislation affecting persons connected with several states. He rejected every mechanistic formula to determine how the court executed its power, such as the formula that if the burden of the regulation on interstate commerce was "direct," it was unconstitutional, but if "only indirect," the regulation was valid. The court, said Stone, must look to all facts and circumstances and determine for itself, without any help from Congress, whether state regulation imperiled the national interest in the free flow of commerce. This required the court openly to make a value judgment.

When the problem was the state's power under the due-process and equal-protection clause of the 14th Amendment to the Constitution to regulate economic enterprise, Stone adhered to the position developed earlier by Holmes and Brandeis that the court should abstain from invalidating the legislation, whatever the individual members thought about the policy of the legislation, as long as anyone could find a reasonable basis for supporting the statute. His unique contribution to the debate concerning the 14th Amendment came in a footnote to *United States v. Carolene Products Co.*, 304 U.S. 144 (1938), where he suggested that while the court should abstain from expressing judgment about economic regulation, it should, in matters concerning personal freedom and conscience and concerning the processes of democracy, such as voting, make a more searching inquiry into the reasonableness of the legislation. In application of this principle he was the lone dissenter in *Minersville District v. Gobitis*, 310 U.S. 586 (1940), wherein the majority held that the state could compel a member of Jehovah's Witnesses actively to participate in the flag salute ceremony. In 1943 the majority of the court switched to Stone's position and held, in *West Virginia Board of Education v. Barnette*, 319 U.S. 624, that such a compulsory flag salute was unconstitutional.

As chief justice during World War II, Stone presided over cases of martial law, military courts, and treason, many of which involved constitutional matters presented to the Supreme Court for the first time in U.S. history. The court was convened in special session that the German saboteurs might have their conviction reviewed without delay and in accordance with standards of due process. Later the court passed on the validity of the "war trial" of the Japanese General Tomoyuki Yamashita; the validity of the curfew for reasons of defense of the West Coast; and the question whether military tribunals could supersede civilian courts in Hawaii.

During his 22 years on the court, Stone wrote more than 600 opinions and dissents. While they cover the entire range of judicial business, the accidents of history projected him into the limelight for his work in the field of constitutional law.

In one of his more famous dissents, *U.S. v. Butler*, 297 U.S. 1 (1936), involving the constitutionality of the first Agricultural Adjustment Act of the New Deal, he expressed one of the great problems of judicial review of executive and legislative action

BROWN BROTHERS

HARLAN FISKE STONE. PHOTOGRAPHED ABOUT 1938

when he said that "while unconstitutional exercise of power by the executive and legislative branches of the Government is subject to judicial restraint, the only check upon our own exercise of power is our own sense of restraint." Stone's conduct on the court indicated how thoroughly he subordinated self-interest and applied this principle. As Stone's biographers point out, some of Stone's passionate dissents, such as the one in the case cited above, found him upholding legislation which, if he had been a legislator, he would have passionately denounced.

Stone was stricken on the bench while reading a dissent in the case of *Girouard v. U.S.*, 328 U.S. 61 (1946), involving the question whether unwillingness to bear arms because of pacifistic religious belief was a bar to naturalization. In 1931, when this question had first come to the Supreme Court, Stone joined in a dissent declaring that the act of Congress should not be construed to bar naturalization. In 1946 the court changed its position to adopt Stone's original dissenting position, but he again dissented on the ground that subsequent consideration by Congress had confirmed the interpretation of the statute that he had earlier thought erroneous. Thus his last act on the Supreme Court was a dramatic illustration of his deference to the legislative will as he saw it.

(A. Dm.)

**STONE, LUCY** (1818–1893), U.S. women's rights leader, was born in West Brookfield, Mass., Aug. 13, 1818. Saddened by the inequalities then imposed upon women and determined to find out whether the scriptural texts regarding their subjection were correctly translated, she put herself through Oberlin, the only college then open to women, and graduated in 1847. The following year, already recognized as a gifted speaker, she was engaged as a lecturer by the Massachusetts Anti-Slavery Society, and soon obtained permission to speak part of each week for women's rights, on her own responsibility. She was instrumental in organizing women's rights conventions in the 1850s, including the first one of national character at Worcester, Mass., in 1850. In 1855 she married Henry B. Blackwell, an Ohio abolitionist. The couple issued at that time a public protest against the unequal laws applicable to married women, and agreed that she would retain her own name and be known as Mrs. Stone. Jointly working for suffrage as residents of New Jersey for over a decade, she and her husband were called to Boston in 1868 by the newly formed New England Woman Suffrage Association. In 1869 they helped establish the American Woman Suffrage Association, a nationwide organization that worked for woman suffrage by state legislation while the National Woman Suffrage Association urged a federal constitutional amendment. In 1870 Mrs. Stone and her husband helped found in Boston the *Woman's Journal*, a woman suffrage weekly, and assumed responsibility for editing it in 1872. Thereafter until 1917 this paper and *Woman Suffrage Leaflets*, both under Blackwell editorship, were major influences in extending the suffrage movement. Mrs. Stone also took a leading role in introducing suffrage articles into the metropolitan press of the country, while Mr. Blackwell initiated a movement to organize suffragists locally for political action. They thus paved the way for the educational, organizational, and political work of Carrie Chapman Catt (*q.v.*) after 1895. Mrs. Stone died Oct. 18, 1893.

**STONE, NICHOLAS** (1586?–1647), the most important English mason-sculptor of the early 17th century. A native of Woodbury, near Exeter, Devon, he was apprenticed in London to Isaac James, a Flemish refugee, and after 1606 spent seven years as a journeyman in Amsterdam with Hendrik de Keyser, the leading Dutch architect and sculptor, whose daughter he married. On his return he set up a workshop in London and quickly acquired a large practice as a tomb sculptor and mason. About 80 monuments are recorded in his notebook in the Soane museum, London. There is also an account book covering the years 1631–42, which throws interesting light on the organization of a big mason's yard.

Stone's earliest monuments—the Bodley monument at Merton college, Oxford (1615); Lady Carey (1617) at Church Stowe, Northamptonshire; or Sir Charles Morrison (1619) at Watford, Hertfordshire—show links with the style of the Low Countries and with late Elizabethan work. The architectural settings are florid, much use is often made of coloured alabasters and of brightly blazoned shields. The figure sculpture is, however, naturalistic and sensitively cut.

In the next decade Stone began to be aware of Italian art. From 1619 to 1622 he served as master mason under Inigo Jones at the Banqueting house at Whitehall and became master mason to the crown in 1632. He was concerned with the repairs of the antique sculpture bought by Charles I, and the knowledge he thus gained of classical art undoubtedly affected his style. Much of his later work, *e.g.*, the second Morrison tomb (1630) at Watford or the Lyttelton monument (1634) at Magdalen college, Oxford, is more classical both in the drapery treatment and in the architectural settings. Because of the extensive use of assistants, however, his later work is uneven in quality.

He also undertook a large number of masonry contracts for royal palaces. He could design as well as build—the gateway to the Botanic garden (1632), and probably the porch of St. Mary the Virgin, at Oxford are his, as were Goldsmiths' hall, London (now destroyed), and parts of Cornbury house, Oxfordshire. He built York Water gate, London, but whether he designed it is uncertain.

Nicholas Stone was an excellent craftsman and his best sculpture has some distinction, but he cannot be regarded as an artist of high rank. He died at his house in Long Acre, London, on Aug. 24, 1647.

*The Note-Book and Account Book of Nicholas Stone* was edited by W. L. Spiers (Walpole society, vii, 1918). (M. D. Wv.)

**STONE**, as the word is most generally used, is a piece of rock (*see* PETROLOGY) or of the solid crust of the earth, and hence of natural origin and generally of inorganic composition.

By their resemblance to rock fragments, however, many objects that originate artificially are also called stone. Examples are commercial grindstones and whetstones (commonly made of crushed natural mineral substances cemented together artificially). A frequent but even more divergent use of the word is the medical one: gallstones and the like are physiologically secreted materials, also known as concretions (*see* URINARY SYSTEM; LIVER AND GALL-BLADDER, DISEASES OF). Because of their hardness, the seeds of some vegetables and fruits (*e.g.*, peaches) are called stones. Kinds of stones or rocks are distinguished by prefixes, *e.g.*, limestone, sandstone. To describe its use by man the word stone may have a prefix, *e.g.*, gemstone, millstone. The term is applied to markers used in surveying or building (*e.g.*, cornerstones).

Finally, stone is used somewhat archaically for units of weight, especially in Great Britain—the legal unit of measure, the stone (14 lb. avoirdupois), the stone of the wool weighers (formerly, and still in Scotland, 24; later usually 14 lb.), the Smithfield or butcher's stone (8 lb.; unofficial but still in use). The word has special meanings in certain trades, *e.g.*, a defect in glass, generally caused by foreign material, the glassmakers' stone, and a flat surface for assembling type known to printers as a stone for historical reasons.

#### GENERAL USES OF STONE

When used for a fragment of rock, stone is widely applied to building material—for example, a house of stone, a stone wall. The stone may be crushed (crushed rock, crushed stone) or ground. Or the rock may be broken, quarried, cut or blasted, along natural lines of weakness. The resulting blocks, if large but irregular, are riprap; if more or less polygonal, thin slabs, they are flagging or flagstones. If sized to fairly definite dimensions, they are dimension stones, and if cut, cut stones. Boulders, pebbles or gravel are terms reserved, respectively, for the individual, generally large rounded pieces of stone, for such pieces when smaller and for masses of such boulders or pebbles, frequently embedded in sand or clay. Aggregate is used in the United States for pebbles, crushed stone or their natural or artificial substitutes which,

when mixed with cement as binder, give concrete. Much stone is raw material for industrial processes. Important instances are in making glass and various refractories, in smelting several ores especially iron ore to make pig iron, in preparing cements notably portland cement, and in the chemical industries, where limestone is an inexpensive, widely available basic chemical material.

### BUILDING STONE

**Structural Features.**—Most stone will split along pre-existing or incipient planes of weakness. If originally laid down as a sediment, stone will part (after consolidation or cementation) parallel to bedding planes or stratification, though such planes may heal or be otherwise obliterated. The partings separating the beds may be closely or widely spaced, ranging from fractions of a millimetre to thicknesses of several feet. If the rock has been compressed in mountain building or folding, with or without heating, it may be dynamically metamorphosed and recrystallized (*see* METAMORPHISM). In such cases, cleavage planes are developed parallel to the most numerous and most flat surfaces of the constituent minerals. Examples are many schists and slates. Such parting planes, perhaps only millimetres apart, may transect the bedding at almost any angle. Slate also may have a much less well-defined tendency to fracture normal to the cleavage—the sculp or grain of quarrying. If once molten and later solidified in its present position—igneous rock, technically—stone may show some tendency to part along two ill-defined directions, rift and grain, normally about at right angles to each other and to the surface of the ground; further, it may have a tendency to part along nearly horizontal but gently curved planes (sheeting).

Almost all rocks have been slightly compressed or have been shrunken by drying or cooling and therefore show real or incipient parting, distinct from the planes already described. This may follow a regular pattern, giving jointing, which yields rectangular or rhombohedral blocks—forms obviously desirable for use in foundations, walls or pavements.

**Quarrying and Preparation.**—If the stone is to be used in bulk (as for ballast or chemical raw material), the quarry operation may be preceded by stripping useless material, followed by drilling holes into the rock and blasting it to size suitable for transport. Wherever possible, such operations are mechanized. They may be followed by crushing the rock in a gyrator, a heavy vertical spindle rotating within a hard metal collar, against which the rock is crushed. Or crushing may be by two metal jaws that close upon the rock as it is fed between them. Further stages of crushing or grinding, grading by screens or washing or a similar process may follow. If the stone must meet dimensions, the parting planes previously mentioned may be exploited in quarrying. Holes are drilled from the exposed surface to the level of an observed or inferred parting plane. Through these are introduced a gas or water under pressure, or explosives to make the rock break along the desired plane of weakness. Other surfaces are separated from the solid rock in like manner, until an approximately regular block of desired size is freed. Alternative methods of quarrying are by channeler, a chisel-like blade rapidly forced against the rock, cutting a groove; by drilling a line of holes close together and broaching (breaking) the rock between; or by wire saw, a continuous wire which moves under tension dragging sand across the stone, thus sawing its way through. A block is next usually transported to a shed where it is sawed on a movable table or with a movable saw, toothed with hard alloys. Or the large block is cut, as in much marble production, with one or several parallel bands of hard steel swinging across one surface, sprayed with water and fed with abrasive sand. Such methods reduce the block to pieces approximating the desired thinness for possible use as facing (veneer). Blocks also may be trimmed to size and shape by hand or by smaller carborundum or other hard alloy saws, drilled if they are to be bolted in place, and polished. Polishing is on a sand bed, a rotating, horizontal disk, moving under the stone to be polished and carrying sand as abrasive. Another polishing device consists of one or several polishing heads that rotate while pressing against the slab from above and are operated manually or, more commonly, mechanically. Further processing depends upon

special requirements—the more processing, the higher the unit value. (*See also* QUARRYING.)

**Natural Features Affecting Use.**—Factors affecting the use of stone for roadbeds, ballast, dam and embankment facing, construction of bridge piers, supporting walls, roofing or facing of buildings, surfacing of areas of much wear (like stairs) and of little wear (like shower stalls), decoration of tables and chairs, veneering of interiors of buildings and for statuary are as varied as the uses to which the stone is put. Special uses are mentioned below in discussing the appropriate stone.

Such properties as resistance to abrasion or sudden shock, and the tendency to fracture or spall when heated are normally considered in selecting the stone to be used for ballast or concrete aggregate. Various tests may be used to determine hardness, resistance to surface abrasion, or relative resistance to impact. Crushing strength tests are also used, especially with structural stone for foundations of dams, bridges and large buildings.

Porous rock may absorb water and, on the freezing of the water, will spall or chip with changes in temperature. Accelerated freezing tests, using some soluble compound that expands as it crystallizes and is introduced into the rock in solution, have proved useful in determining freezing resistance.

For decoration, critical properties are colour, texture and resistance to disfiguring developments (such as pitting, staining and spalling). Colour varies with the mineral constituents. Pink, red, brown and yellow are usually due to iron minerals, especially hematite and limonite. But granitelike stone is pinkish because of potassium feldspars. Grays may be due to carbon or dark minerals like amphiboles, pyroxenes and micas—silicates usually containing some iron. Green is usually from magnesium or iron silicates. Bluish gray and rare blue are commonly fundamentally black, but if iridescent, may indicate calcic or sodic feldspars, as in some of the iridescent peacock-coloured dark rocks from Scandinavia. White and light gray chiefly result from quartz, feldspars, calcite and clay minerals. Colours do not necessarily reflect major constituents; stones containing 99% white quartz may be rusty brown because of 1% iron oxide, a strong tinting agent.

Texture is important in many ways. Some rocks, such as certain lavas are extremely porous. Stone of mixed grain sizes does not polish as readily as one more uniform in grain. Marble too coarsely granular cannot be worked easily for statuary. Nevertheless, highly porous travertine with irregularly wavy pattern is at a premium as a decorative stone, and rocks with conspicuous veins, crystals, fossils or fragments (breccias) are valued for interior decoration. Similarly, sea-green and light-gray wavelike patterns in certain marbles are much in demand and so are matched panels, cut and set into patterned designs.

**Kinds and Sources of Stones.**—As suggested, building stones fall into three geologic classes: sedimentary, igneous and metamorphic. The first includes limestone (and its magnesium-bearing variety, dolomite), sandstone and the rarely used shale. Some marbles are properly limestones. Igneous building stones include granite and related light-coloured (acid) coarsely crystalline igneous rocks, basalt or trap and other dark-coloured (basic) igneous rocks, largely fine-grained but partly coarsely crystalline, like diorite and gabbro and fine-grained, light-coloured lavas and volcanic tuffs. Among the metamorphic rocks, marble, slate, gneiss, schist and serpentine are most used.

Of all types, limestone and dolomite, or magnesian limestone, find the largest and most versatile use. Being sedimentary rock, with the beds in many places essentially horizontal, these are commonly easily quarried. The uses of limestone and dolomite are highly varied—as a flux in metallurgy, particularly ironmaking, as a basic chemical raw material (if not too high in magnesium), as a source of coarse crushed stone, or road metal, and aggregate in concrete wherever available and as a satisfactory foundation, building and facing stone. Thus, limestone and dolomite yield more tons of stone in the United States than any other. Generally white to gray and fine textured, it may grade into the coarsely crystalline texture of marble. A major producing region is near Bedford, Ind. Characteristic of the Bedford limestones and those of southern England and northwestern France are the small pellets

or oölites, suggesting fish roe, composing them (see OÖLITE). Limestone is also available on tropical coasts in the form of coral-line lime if of corallike origin, and of coquina if composed of shell fragments.

Second in quantity used as building stone is sandstone. It ranges in colour from white through buff, red and dark brown. It consists of sand grains cemented with silica, calcium carbonate or clay. The porosity of certain sandstones makes them subject to water ingress and spalling. As coarseness increases sandstone grades into grit and finally conglomerate (cemented gravel). Sandstone is widely quarried for building, especially in western Europe and the United States (Ohio, New York, Wisconsin, Pennsylvania and New Jersey). Unlike limestone, it serves little use in industry except in glass and refractories.

Similar to sandstone in quantity used is granite (*q.v.*), a term loosely but inaccurately applied to most light-coloured, coarsely grained igneous stone. Granite is highly useful for crushed and building stone and for monuments and decoration. Its great variety of colours—from white through gray, pink, greenish and almost to black—and of coarseness of grain make it much in demand. Productive localities include especially the Scandinavian countries, Scotland, Canada and New England.

Many dark-coloured igneous rocks (gabbro, andesite, basalt, diabase) are collectively sold as trap and used chiefly in crushed stone for roads and aggregate. Typical localities of production are central France and western Scotland, and Washington, Oregon and New Jersey in the United States.

Marble is a recrystallized and commonly beautifully banded limestone. Its original layers may be greatly contorted, or shattered and recemented, resulting in strikingly contrasting colours and patterns. Its chief use is for decoration—mainly indoors—and for statuary. Famous sources are Italy, Greece, Egypt and Tennessee and Vermont.

Slate is a gray to red, green, mottled or black stone marked by closely spaced and splitting cleavage planes. It is used chiefly for roofing, blackboards, switchboards and partitions, but also as structural stone. Outstanding producing regions are Wales, France, Germany, Switzerland, Belgium, and the eastern United States (Pennsylvania, New York, Vermont and Maine). Similar foliated rocks with wavy cleavage, called schists, are locally used.

Serpentine and related types veined with white calcite (ophicalcite, verd antique) are massive and greenish, generally ranging from almost chartreuse to olive. They are used for counters and panels. Though widespread, large deposits are rare. Travertine, a hot-spring deposit, usually porous, and onyx, generally a precipitate from underground waters in caves, are other decorative stones.

**STONEHENGE**, a circular setting of large standing stones surrounded by an earthwork about 8 mi. (13 km.) N of Salisbury, Wiltshire, Eng., was built during Late Neolithic to Early Bronze Age (1800–1400 B.C.). Among the earliest references to it is that of Geoffrey of Monmouth, who related in *Historia regum Britannie* (c. A.D. 1136) the legend that the stones were magically transported from Ireland by Merlin (*q.v.*). This legend perhaps enshrines a folk memory of the bringing from Pembrokeshire of the "bluestones" which form part of the monument. The supposed connection of Stonehenge with the Druids, which, though without foundation, has held the public imagination since the 17th century,

originated with John Aubrey (1626–97), and was more particularly elaborated by William Stukeley in 1740 (see DRUIDISM). The modern interpretation of the monument is based chiefly on excavations carried out by the Society of Antiquaries of London from 1919.

The monument consists of a number of structural elements, mostly circular in plan. On the outside is a circular ditch, broken by an entrance gap on the northeast, with a bank immediately within it.

Inside the bank is a ring of 56 pits, known after their discoverer as the Aubrey holes. Between these and the stones in the centre are two further rings of pits, now invisible on the surface, known as the Z and Y holes. The stone setting consisted of two circles (the outer of sarsen [Tertiary sandstone], the inner of bluestone) and two horseshoes of uprights (the outer of sarsen, the inner of bluestone), the outer circle and the outer horseshoe being capped by stone lintels. Additional stones include the Altar stone, lying on the axis southwest of the centre; the Slaughter stone inside the entrance of the earthwork; two Station stones just within the bank on the northwest and southeast; and the Heel ("Hele") stone, standing on the Avenue outside the entrance and surrounded by a narrow circular ditch.

Similar ditches enclose two flat areas on the inner edge of the bank, known as the North and South barrows, with empty stone-holes at their centres.

Excavations between 1950 and 1964 suggested three main periods of building (Stonehenge I, II, and III), the last of which can be divided into three phases (Stonehenge IIIa, IIIb, and IIIc).

Stonehenge I (built in the Late Neolithic about 1800 B.C.) comprised the circular ditch and bank, the Aubrey holes, and the Heel stone. There may have been some structure of stone or timber at the centre of the circle, but little or nothing of it is likely to have survived disturbance by treasure hunters. The bank, now reduced by weathering to a height nowhere more than 2 ft., has a mean diameter of 320 ft. (98 m.), and was broken by an entrance gap 35 ft. (10.7 m.) wide on the northeast side. It

ADAPTED, BY PERMISSION, FROM MINISTRY OF PUBLIC BUILDING AND WORKS PLAN  
STONEHENGE PLAN SHOWING STONES, EXCAVATED STRUCTURES, AND THE SOLSTITIAL ALIGNMENT OF THE AXIS OF SYMMETRY

was built of chalk rubble quarried from the surrounding ditch. The latter is irregular in plan and depth, and consists of a series of interconnected pits up to 7 ft. (2.1 m.) deep, with steep sides and flat bottoms.

The Aubrey holes form a circle 288 ft. in diameter (87.8 m.). They are round pits up to 6 ft. (1.8 m.) in diameter and 4 ft. (1.2 m.) in depth, with steep sides and flat bottoms. They appear to have been deliberately filled soon after their excavation with the chalk rubble dug from them, some of which meanwhile had been burned. Many of them contain cremated human bones, in most cases inserted later as secondary deposits, though still within the first phase of the monument's history. Similar cremated remains form a cemetery of about 30 burials in the eastern half of the bank and the silting of the ditch.

The Heel stone, a 35-ton block of sarsen 16 ft. (4.9 m.) high, stands outside the entrance of the earthwork, but not on its axis of symmetry. West of it, astride this axis, four large postholes probably represent a former timber gateway. A pair of stones, later removed, appears to have stood centrally in the gap in the bank, northwest of the present position of the Slaughter stone.

In Stonehenge II (probably 17th century B.C.) the entrance of the earthwork was widened on the east side, and was joined to the River Avon (about 2 mi. [3.2 km.] to the east) by the Avenue, a processional way marked by parallel banks and ditches. This enclosed the Heel stone, which was now symbolically protected by the digging, and immediate refilling, of the ditch that surrounds it. At the same time a number of natural slabs and pillars of igneous rock (diabase, rhyolite, and volcanic ash) called bluestones were transported from the Prescelly Mountains in Pembrokeshire, southwest Wales, and erected in the centre of the site to form two concentric circles about 74 ft. and 86 ft. (22.6 m. and 26.2 m.) in diameter. Each radial pair of these stones stood at the ends of an elongated stone-hole straddling the line later followed by the bluestone circle (erected in period IIIc). The entrance of this earliest setting of bluestones was marked by additional inlying pillars, and was aligned approximately upon the sunrise at the summer solstice, the alignment being continued by the section of the Avenue nearest Stonehenge. The double circle seems to have been designed to contain about 40 pairs of stones, but was never completed and was dismantled in the next phase (IIIa). Excavation has shown that at least a quarter of its circumference on the west side was still unfinished when the stones already erected were dismantled. The work of this period is probably to be attributed to the Beaker people of the Late Neolithic (see *EUROPE: Archaeology: Middle and Late Neolithic*).

In Stonehenge IIIa (soon after 1600 B.C.) the monument was remodeled. About 80 large blocks of sarsen were transported from the Marlborough Downs 20 mi. (32 km.) to the north and were erected in a circle of 30 uprights capped by a continuous ring of stone lintels, enclosing a horseshoe of five trilithons, each formed of a pair of uprights supporting a lintel. The four Station stones (two of which have vanished), and the Slaughter stone and its vanished companion, also of sarsen, appear to belong to this phase.

This sarsen structure is unique among the megalithic monuments of Europe. Its stones are of exceptional size, up to 30 ft. (9.1 m.) long and 50 tons in weight. Their visible surfaces have been laboriously dressed smooth by pounding with stone hammers; the same technique was used to form the mortise-and-tenon joints by which the lintels are held on their uprights, and the tongue-and-groove joints by which the lintels of the circle fit together. The lintels are cut to the curve of the arcs on which they lie; those of the trilithons have been carefully shaped to a trapezoidal cross section.

Unparalleled in European megalithic architecture, these refinements suggest influence from Mycenaean Greece and Minoan Crete, a hypothesis supported by carvings of Bronze Age weapons discovered (1953) on four of the sarsen stones. Most of these are full-scale representations of Early Bronze Age axeheads of a type current in Britain between 1600 and 1400 B.C.; but there is also a single carving of a hilted dagger that can best be matched with weapons from the shaft graves of Mycenae. This identifica-

tion (though a matter of opinion) is supported by the presence of objects of Mediterranean origin in many of the rich barrow burials of the Early Bronze Age that cluster densely around Stonehenge. On this evidence the building of the sarsen structure may be assigned to the earlier half of the 16th century B.C., broadly confirmed by a radiocarbon estimate giving a probable range of 2000 to 1400 B.C. (see *RADIOCARBON DATING*).

In Stonehenge IIIB, which probably followed immediately, about 20 bluestones were selected from the dismantled components of Stonehenge II and dressed to shape with stone hammers. These were erected in an oval setting, largely coincident with the line of the present inner horseshoe of bluestones. This arrangement contained at least two bluestone trilithons with mortise-and-tenon

AEROFILMS LTD

AERIAL VIEW OF STONEHENGE, SEEN FROM THE SOUTH; HEEL STONE AT RIGHT CORNER

joints, and a pair of contiguous pillars joined by a vertical tongue and groove. It seems to have been the intention to erect the remaining bluestones in the two circles of Y and Z holes, which are roughly concentric with the sarsen circle; but this plan clearly was never carried out. The holes on the southeast side were never completed; both circles were left open to silt up over the succeeding centuries.

The abandonment of this plan marks the end of phase IIIB and was probably followed at once by the final period of building (Stonehenge IIIC) likely to have been completed before the end of the Early Bronze Age about 1400 B.C. The phase IIIB oval structure of dressed and jointed bluestones in the centre was dismantled; and its bluestones, as well as those lying on or near the site since the dismantling of the phase II circles during phase IIIa, were rearranged into the bluestone circle and horseshoe whose remains can be seen today. Most of the components of the dismantled oval were reused as uprights in the final horseshoe, perhaps after some reshaping to give a sequence of straight-sided square pillars alternating with flatter, tapering obelisks. The Altar stone (of micaceous sandstone from the shores of Milford Haven in Pembrokeshire) apparently stood as a pillar at the focal point of the horseshoe, subsequently falling to cover its own stone-hole.

It is generally and probably rightly assumed that Stonehenge was constructed as a place of worship; but in the absence of contemporary documentary evidence the nature of the religion it served must remain conjectural. The solstitial alignment of the axis of symmetry of the sarsen structure (Stonehenge IIIa) has long been recognized, and is now known to have perpetuated a similar alignment in the earlier double circle of bluestones (Stonehenge II). In 1963 the existence of additional alignments of significant risings and settings of the sun and moon was suggested independently by C. A. Newham in England and by G. S. Hawkins in the U.S. These suggestions undoubtedly reinforce the popular belief that Stonehenge was a temple for sky worship, but should be considered with caution since most Christian churches are likewise astronomically orientated.

Hawkins also suggested that the circle of 56 Aubrey holes could have been used as a counting device for predicting significant risings of the moon, and eclipses of the moon and sun. The possibility cannot be denied, but its likelihood is open to question if only because the Aubrey holes (refilled very soon after they

were opened) would have been ill-adapted as permanent markers over several centuries. They also belong to the first Stonehenge, representing a culture and technology markedly more primitive than that of the later stages of construction.

Between 1918 (when the monument was presented to the British nation) and 1964 more than half the surviving sarsen pillars were restored or straightened, and consolidated in concrete foundations, including stones that fell accidentally in 1797, 1900, and 1963.

**STONY POINT**, a town of Rockland County, N.Y., U.S., lies in the scenic highlands along the west shore of the Hudson River and about 38 mi. (61 km.) from midtown New York City. Stony Point derives its name from the rocky promontory jutting into the Hudson. A part of Palisades Interstate Park lies within the town limits. At the town's northern point was anchored one end of the heavy chain stretched across the Hudson during the American Revolution to prevent the British fleet from ascending further, while at the southern limits stood the Treason (Joshua Hett Smith) house where Gen. Benedict Arnold and Maj. John André met on Sept. 21, 1780, to arrange for Arnold's betrayal of West Point to the British. At midnight on July 16, 1779, occurred the successful and daring storming of the strong British fortifications at Stony Point by Gen. Anthony Wayne and about 1,350 gallant, hand-picked American troops. Wayne's feat, with a loss of 15 killed and 83 wounded as against 63 British killed and 70 wounded, and the capture of 543 of the garrison, was a severe setback to the British. As the fort was undefendable against river bombardment, however, it was speedily dismantled and evacuated on July 18; the British thereupon reoccupied it a second time but abandoned it late in Oct. 1779, and the upper Hudson was thereafter safe for the Americans.

Major products include chemicals, traprock, and gypsum. Stony Point is governed by a town board consisting of a supervisor, two justices of the peace, and two councilmen.

For comparative population figures see table in NEW YORK: Population.

**STOPEs, MARIE CARMICHAEL** (1880–1958), British pioneer of the birth control movement, was born in Edinburgh, Scot., on Oct. 15, 1880. She graduated in botany and geology at University College, London, in 1903, obtained a doctorate in botany at the University of Munich in 1904, and became a lecturer at Manchester University. A specialist on fossil plants and problems of coal mining, she had established a considerable academic reputation when the failure of her first marriage, which was annulled in 1916, focused her thought on problems of marriage, and on birth control as an aid to marriage fulfillment and as a means to save women from the burdens of excessive childbearing. Humphrey Verdon Roe, the aircraft pioneer, whom she married in 1918, helped her in the crusade which she now began. Her *Married Love and Wise Parenthood*, both of which appeared in 1918, had many editions and translations. In 1921 Marie Stopes founded the United Kingdom's first birth control clinic. When her *Contraception: Its Theory, History and Practice* appeared in 1923 it was the most comprehensive work of its kind.

The fervor of Marie Stopes's writings and speeches evoked violent opposition, especially from Roman Catholics, which gave wide publicity to her movement and to herself. She did most to pave the way for the Church of England's change of stand on birth control, as reflected in the reports of successive Lambeth Conferences. After World War II she worked to promote birth control in Far Eastern countries, and continued her interest in coal research. She died at Norbury Park, near Dorking, Surrey, on Oct. 2, 1958. See also BIRTH CONTROL.

See K. Briant, *Passionate Paradox: the Life of Marie Stopes* (1962).

**STORACE, STEPHEN** (1762–1796), English composer who introduced the classical Italianate style of Vienna into English

opera, was born in London on April 4, 1762. The son of an Italian double-bass player resident in Britain and of an English mother, he was trained at the S. Onofrio conservatory in Naples. In 1784 he joined his sister, the singer Ann Selina (known as Nancy) Storace (1765–1817) in Vienna and took lessons there from Mozart. His first two operas, *Gli sposi malcontenti* (1785) and *Gli equivoci* (1786), were given in Vienna and later in Leipzig, Dresden, and other cities in Germany. The latter, the score of which survives, has an excellent libretto by Lorenzo da Ponte, based on Shakespeare's *The Comedy of Errors*.

In 1786 Nancy Storace created the part of Susanna in Mozart's *Nozze di Figaro*, and the family then returned to London, where Stephen spent the rest of his short life writing English operas for Drury Lane, in which his sister sang the lead. His masterpiece, *The Pirates* (1792), on a Neapolitan plot by James Cobb, is Mozartean in scale and sometimes in style. Of his other full-length operas the most successful was *The Haunted Tower* (1789), with a "Gothic" plot that anticipated the novels of Mrs. Radcliffe. *Dido, Queen of Carthage* (1792) was written in emulation of T. A. Arne's *Artaxerxes*. All Storace's other English operas have spoken dialogue. Of his afterpieces the most successful was *No Song, No Supper* (1790, reprinted, *Musica Britannica*, vol. xvi, 1959, edited by R. Fiske). Storace also published two early examples of the piano quintet, three Mozartean piano trios, and some songs. His anthology, *Storace's Collection of Original Harpsichord Music* (1787–89), includes many works he brought back from Vienna, and he was the first to publish Mozart's piano trio in G (K. 564). Storace's sound training and unrivaled knowledge of the continental repertoire gave his music a style and professionalism lacking in that of his English contemporaries. He died in London on March 19, 1796.

See R. Fiske, "Stephen Storace," in *Proceedings of the Royal Musical Association*, 86th session (1959–60).

(R. E. Fr.)

**STORAGE BATTERY:** see BATTERY.

**STORK**, a large, long-legged, long-necked, large-billed bird related to the heron and ibis and placed with them in the order Ciconiiformes. The 17 species of true storks, which constitute the family Ciconiidae, include the white stork of popular fable, a bird that brings good luck and little babies.

Storks lack the voice box, or syrinx, and so are practically mute, being able only to emit low grunts and hisses; they also clatter their bills. They fly with much soaring, the neck and legs being stretched to their limits. Storks feed during the day, mainly on small aquatic animals caught in marshes; some, like the marabou stork of Africa and the adjutant bird of India, feed primarily on carrion. Storks are found in flocks except during the breeding season when they pair off. The nest, a large twig platform built by both sexes, is constructed in trees, on rock ledges, or, in the white stork, on rooftops and chimneys, often in colonial groupings. Three to six chalky white eggs, spotted, are incubated by both parents for a month or more; the down-clad young are cared for in the nest.

The white stork (*Ciconia ciconia*) breeds across Europe and Asia and winters south to the Cape of Good Hope. It is a stately bird, three to four feet long, with black flight feathers, a dark red bill, and reddish legs. To attract these harbingers of good fortune, the townspeople often put up ready-made platforms on their rooftops. The black stork (*C. nigra*), about the size of its congener and with red bill and legs, is black except for a white belly patch. It is more wary of man and nests in marshes and forest. Like the white stork, its population is decreasing, partly due to continuing destruction of its habitat by man.

The adjutant bird (*Leptoptilius dubius*) is distinguished by its dull plumage, black scabrous head, and enormous breast pouch; the last is of doubtful function, connected with the respiratory system. The bird is 6 or 7 ft. tall. Related species are the lesser adjutant (*L. javanicus*), of southeast Asia, and the African adjutant, or marabou stork (*L. crumeniferus*). The original marabou feathers of commerce were the undertail coverts of the latter bird, but the name has come to be applied to large downy feathers of other birds as well.

The jabiru (*Jabiru mycteria*), an American stork found from

Mexico to the Argentine, stands between four and five feet high, with a massive black bill and white plumage. The head and neck are bare, and black and red in colour. "Jabiru" is often wrongly applied to the wood ibis, or wood stork (*Mycteria americana*), a smaller but somewhat similar bird ranging from Argentina to the coasts from Texas to Florida and North Carolina. These birds and the African wood ibis (*Ibis ibis*) belong to the subfamily Mycteriinae.

The shoebill, shoe-billed stork, or whale-headed stork (*Balaeniceps rex*), is a giant bird from the White Nile. Its affinities are doubtful and it is usually placed in its own family, Balaenicipitidae, either with the Ciconiiformes or the Pelecaniformes. In singularity of aspect few birds surpass the shoebill, with its gaunt gray figure, about five feet high, its large head surmounted by a little curled tuft, its scowling eyes, and its huge bill, in form not unlike a whale's head but tipped with a formidable hook. It forms large flocks and frequents dense swamps. The flight is heronlike, and the birds settle on trees. The food consists of any small animals or carrion. The nest is a hole in dry ground, roughly lined with herbage, and from 2 to 12 chalky white eggs are laid.

Another monospecific family in the Ciconiiformes is the Scopidae. It contains the African hammerkop, or hammer-headed stork (*Scopus umbretta*), a heavy-looking brownish bird about 20 in. long, with short black legs and long black bill, laterally compressed and slightly hooked. Most conspicuous is the long, backward-directed crest.

**STORM, (HANS) THEODOR WOLDSSEN** (1817–1888), German writer, whose poems and *Novellen* are the outstanding expression of poetic realism in northern Germany. He was born on Sept. 14, 1817, at Husum, on the west coast of Schleswig, where he practised law until Schleswig's incorporation in Denmark made him move to Potsdam in 1853. In 1856 he was transferred to Heiligenstadt, Thuringia, as magistrate. When Denmark released Schleswig in 1864, Storm returned to Husum. In 1880 he retired to the village of Hademarschen, where he died on July 4, 1888.

Storm's lyrics (*Liederbuch dreier Freunde*, with T. and T. Mommsen, 1843; *Gedichte*, 1852) are songlike and direct in feeling, the work of a sensitive, fundamentally happy nature which inclined to melancholy resignation, however, in the face of reality. The main themes are love and friendship, a feeling for home, and an appreciation of nature. Only in his political poems, occasioned by the Danish occupation of Schleswig, is there any sense of antagonism. Although the mood of the early stories—notably *Immensee* (1852; first English translation, 1863), a moving story of the vanished happiness of childhood—is that of the lyrics, his *Novellen* soon surpassed his poetry in importance. In the 11 stories written at Heiligenstadt, of which *Im Schloss* (1861)—the portrayal of a decadent aristocracy—is the most notable, he achieved closer contact with life and a wider range of motifs. Then, after five barren years following his wife's death in 1865, he poured forth a succession of more mature *Novellen*, affirming life in both its lighter and its tragic aspects. They include *Viola tricolor* (1874; Eng. trans., 1956), *Pole Poppenspäler* (1875), *Aquis submersus* (1877; Eng. trans., 1910), and *Carsten Curator* (1878; Eng. trans., 1956). His last *Novelle*, *Der Schimmelreiter* (1888; Eng. trans., *The Rider on the White Horse*, 1917), with its objective approach, its terse style, and its forceful hero, is typical of Storm's later work and is probably his masterpiece.

**BIBLIOGRAPHY.**—*Editions, etc.*: *Sämtliche Schriften*, so-called Westermann ed., 19 vol. (1868–89), giving Storm's final arrangement of his writings; *Sämtliche Werke*, critical edition by A. Köster, 8 vol. (1919–20); *Ausgewählte Werke*, selections ed. by K. Hoppe, 4 vol. (1948–49); *Gesamt-Ausgabe*, ed. by H. Engelhard, 3 vol. (1958). Of the many editions of correspondence see G. Storm (ed.), *Briefe*, 4 vol. (1915–17); P. Goldammer (ed.), *Der Briefwechsel zwischen T. Storm und G. Keller* (1960).

Wooley, *Studies in T. Storm* (1943); F. Stuckert, *T. Storm: sein Leben und seine Welt* (1955); F. Böttger, *T. Storm in seiner Zeit* (1959). (K. HE.)

**STÖRMER, FREDRIK CARL MÜLERTZ** (1874–1957), Norwegian mathematician and geophysicist who developed a

mathematical theory of auroral phenomena, was born at Skien, Sept. 3, 1874. Professor of mathematics at the University of Oslo, 1903–46, Störmer began his scientific work in pure mathematics, particularly number theory. In 1904 he became interested in experiments of the physicist Kristian Birkeland, in which aurora effects were obtained by electron bombardment of a terrella (a magnetized sphere to simulate the earth) in vacuum. Störmer calculated the trajectories of electrical particles in the field of a magnetic dipole and explained many of the peculiarities of the aurora borealis. The results are also applicable to cosmic rays (see AURORA POLARIS).

In 1910 he spent a winter at Bossekop, in the northernmost Norwegian county of Finnmark, observing auroras; later he organized a permanent network of stations in Norway to photograph and measure the heights of auroras and special types of clouds. Störmer was a member of numerous geophysical commissions and received a great number of scientific distinctions. He died at Oslo on Aug. 13, 1957.

See Carl Störmer, *The Polar Aurora* (1955); Royal Society of London, *Biographical Memoirs of Fellows of the Royal Society*, p. 257–279 (1958). (O. OR.)

**STORMONT**, the seat of the Northern Ireland government, is situated in a 300-ac. estate about 4 mi. E of the centre of Belfast. The parliament building (1928), built in the Greek classical tradition, has four main floors and accommodates the House of Commons and Senate chambers, together with offices for various administrative departments. The building is approached by a wide processional drive, about  $\frac{1}{2}$  mi. in length, which is bordered by sweeping lawns and trees. The estate, most of which is open to the public, provides one of the most striking landscapes in Northern Ireland. It includes Stormont House, the official residence of the prime minister.

**STORNOWAY**, a small burgh on the island of Lewis-and-Harris (q.v.), Outer Hebrides, Scot., 53 mi. (85 km.) N of Portree, Isle of Skye, by steamer. Pop. (1961) 5,229. It is the biggest town in the county of Ross and Cromarty and is a natural harbour. There is about  $\frac{1}{2}$  mi. of quayage and wharfage. The herring fishery, formerly much larger, declined when the shoals were depleted and the continental market collapsed. Stornoway's chief occupation is now the manufacture of Harris tweed, and the town is the service centre of the northern Hebrides. The parish of Stornoway was given to the people by the 1st Lord Leverhulme and is administered by the Stornoway Trust from offices in the burgh. The castle is a 19th-century building now used as a museum. There is daily steamship connection with Kyle of Lochalsh and Mallaig, air services with Glasgow and Inverness, and weekly cargo services to Aberdeen, Dundee, Leith, Glasgow, and Liverpool. (F. F. DO.)

**STORY, JOSEPH** (1779–1845), U.S. legal writer and educator, associate justice of the U.S. supreme court and a principal juristic supporter, with Chief Justice John Marshall (q.v.), of American nationalism, was born on Sept. 18, 1779, at Marblehead, Mass. One of the great figures in U.S. legal history, his influence on the development of U.S. law rivaled that of Marshall. After preparatory training at the Marblehead academy, he entered Harvard college in Jan. 1795, joining the class admitted the previous term and unsuccessfully contesting with William Ellery Channing (q.v.) for first rank in the class of 1798. Upon graduation, Story returned to Marblehead and began reading law with Samuel Sewall, who later became chief justice of the supreme judicial court of Massachusetts. In 1801, he moved to Salem and entered the office of Samuel Putnam, where he read law until July of that year when he was admitted to the bar.

From 1801 to 1811 Story practised law in Salem and occasionally argued cases in New Hampshire. In Massachusetts he became prominent in the Jeffersonian Republican (afterward called the Democratic) party and, in 1805, was elected to the state legislature. He also served part of one session (1808–09) in the U.S. congress. In 1810, he was counsel in the celebrated case of *Fletcher v. Peck*, in which the U.S. supreme court, for the first time, declared a state law invalid because it conflicted with the constitution. He was returned in 1810 to the Massachusetts legis-

lature, becoming speaker of the state house of representatives in 1811.

**Supreme Court Appointment.**—Appointed an associate justice of the U.S. supreme court by Pres. James Madison in Nov. 1811 to fill the vacancy created by the death of William Cushing, Story was then 32 years old, the youngest justice ever to sit upon that court, and lacking in judicial experience. A leader in the Massachusetts Jeffersonian Republican party, he wrote shortly after receiving the life appointment, "I am no longer a political man." Although he was raised to the bench by Madison for the express purpose of contesting the nationalism of Chief Justice John Marshall, Story himself became a confirmed nationalist and a supporter of the Federalist views of the chief justice.

The supreme court was then composed of seven justices. One term of the court was held each year at Washington in a basement chamber of the old capitol building; in addition, each justice was assigned a "circuit" in which two terms of the court were held. Story's circuit consisted of Maine, Massachusetts, Rhode Island and New Hampshire. His circuit court decisions (reported by Gallison, Mason, Sumner and Story) in admiralty, prize, patent and copyright matters helped make United States law on these subjects.

**Notable Cases.**—The supreme court, which eight years previously had first declared a law of congress unconstitutional (*Marbury v. Madison*), was just entering upon its real importance when Story came to the bench, and many of the cases decided during his tenure established basic principles of U.S. public and constitutional law. Story's supreme court opinions, found in the reports of Cranch, Wheaton, Peters and Howard (1812-45), number more than 200.

In *Martin v. Hunter's Lessee* (1816), a decision that has been called "the keystone of the whole arch of Federal judicial power" (Charles Warren, *The Supreme Court in U.S. History*, p. 449, Little, Brown and Company, Boston, 1922), Story held that the supreme court's appellate civil jurisdiction embraces every case not otherwise to be decided initially and directly by way of its original jurisdiction; that there is no constitutional restraint upon the exercise of this appellate jurisdiction over state tribunals; and that sec. 25 of the Judiciary act of 1789, insofar as it granted such appellate jurisdiction, was constitutional. This decision established the supremacy of the supreme court over the highest court in any state in all civil cases where the federal constitution, laws and treaties were involved. (Five years later, Marshall's opinion in *Cohens v. Virginia* did likewise for state criminal cases.)

Although Marshall wrote the opinion of the court in *Dartmouth College v. Woodward* (1819), holding that charters of private corporations, as then issued, were contracts which could not constitutionally be impaired by the states granting them, Story concurred in a separate opinion—one of his most learned—which reviews English and U.S. authorities and reveals his devotion to higher-law principles. This decision gave stability to the rights of corporations and influenced subsequent economic developments in the United States.

In *Ogden v. Saunders* (1827), the first case in which Marshall was defeated on a constitutional issue, Story joined in a dissenting opinion written by the chief justice. They both took the position that the contract clause of art. i, sec. 10 of the constitution denounced state insolvency legislation concerning the prospective, as well as the retrospective, operation of contracts. This case marked the beginning of a trend away from the principles of economic conservatism which Marshall and Story had sought to entrench in U.S. law.

John Marshall died in July 1835. Story presided over the court while a successor was being chosen, but he was never chief justice. "I have never for a moment imagined that I should be thought of . . ." he wrote on July 24, 1835. Roger Brooke Taney (*q.v.*) was commissioned chief justice in March 1836, and Story served under him until 1845.

Left over from the Marshall period were three cases, involving the constitutionality of state laws, that had been argued orally before the supreme court, but that had gone undecided: *City of New York v. Miln* (1837), *Briscoe v. Bank of Kentucky* (1837)

and *Charles River Bridge v. Warren Bridge* (1837). In all of these cases, the Taney court upheld the state laws, and Story delivered dissenting opinions which lamented the death of Marshall and the passing of the "old order." He now referred to himself as the last of the "old race of judges," and he decided to resign. Friends, however, persuaded him to remain on the bench. Henceforth, on important constitutional issues, he was forced to dissent from the judgments of the Taney court, or to appear to agree in silence with doctrines which seemed to him at variance with his previous decisions.

Two cases decided during this final period, in which Story wrote the opinions of the court, were *Prigg v. the Commonwealth of Pennsylvania* (1842) and *Swift v. Tyson* (1842). In the *Prigg* opinion, Story held that since the constitution gave the federal government the power to deal with fugitive slaves, this power could not be exercised by the states, even if no conflict with federal laws was involved. Further, he expressed doubt that the federal government could compel state officers to enforce federal laws. In the *Swift* case, Story held that sec. 34 of the federal Judiciary act of 1789 did not require that local interpretations of general commercial law be followed in diversity cases in the federal courts. In 1938 the supreme court reversed this decision, holding that the law to be followed in such cases was the law of the state as interpreted by state courts.

**Story and Marshall Compared.**—Marshall, who was 24 years older than Story and versed mainly in constitutional law, disliked the labour of investigating legal authorities to support his judgments. Story, who was the master of several fields of law (including constitutional law), loved legal research, and his opinions drew heavily upon past authorities. If Marshall's opinions were businesslike, Story's were scholarlike; if the chief justice was concise and to the point in his judgments, his younger colleague was eager, luminous and had a tendency to be expansive. The difference between their judicial minds is seen in the Dartmouth college case, where opinions were written by both. Marshall served on the court just over 34 years; Story's tenure lacked only months of equaling that of the chief justice. In the field of constitutional law, they laboured together for nearly a quarter of a century in upholding the same legal doctrines.

**Harvard Professorship.**—In 1829 Nathan Dane founded a professorship of law at Harvard college, the duties of which were to prepare, deliver and revise for publication a course of lectures on the law of nature, the law of nations, commercial and maritime law, federal law and federal equity. By an express condition of the \$10,000 endowment, Story became the first Dane professor of law at Harvard, which position he held, together with that of associate justice of the supreme court, until his death in 1845. Story's lectures on the designated subjects led to the publication of his nine great commentaries on the law, the first of which appeared in 1832. His first associate at the law school was John Hooker Ashmun, Royall professor of law, who died in 1833 and was replaced by Simon Greenleaf. The Story-Greenleaf period marked the beginning of the law school's growth to greatness. Story was exceptional as a teacher, and he devoted a great deal of time to the practical presentation of moot-court cases and arguments by his students. His annual salary at Harvard was \$1,000.

In 1845 Story resolved to resign from the supreme court and devote his life to teaching and writing at Harvard. Early in September, however, before his letter of resignation was sent to Washington, he became ill, and on Sept. 10, 1845, he died at his home in Cambridge, Mass.

Story was married in 1804 to Mary Lynde Fitch Oliver, who died without issue; and in 1808 to Sarah Waldo Wetmore (1784-1855), the daughter of a Boston jurist, who bore him seven children, only two of whom survived childhood. A Calvinist, Story became a Unitarian and was several times president of the American Unitarian association.

**Writings.**—Story is best known as an author for a series of commentaries on *Bailments* (1832), *Constitution of the United States*, 3 vol. (1833), *Conflict of Laws* (1834), *Equity Jurisprudence*, 2 vol. (1836), *Equity Pleading* (1838), *Agency* (1839), *Partnership* (1841), *Bills of Exchange* (1843) and *Promissory*

*Notes* (1845). His works on equity were particularly important; with Chancellor James Kent (*q.v.*), he helped found equity jurisprudence in the United States. He also prepared *Commentaries on the Constitution*, one-vol. abridgment (1833), and *Constitutional Classbook* (1834). He wrote scholarly articles for *The American Jurist* and *The North American Review* and published biographical sketches of many prominent men. He drew up the bylaws of a bank, the *Report of the Massachusetts Commission on Codification* and the *Report on Salaries of the Judiciary* and prepared elaborate notes (for Wheaton's *Reports*) on prize, admiralty, etc. He drafted a bankruptcy law, a crimes act and a judiciary act. He published a volume of poems, constructed a portion of a legal digest and prepared an edition of the laws of the United States. He delivered many public addresses, some on literary, scientific and historical subjects, and participated in the convention called to revise the Massachusetts constitution.

(1851) and *Miscellaneous Writings of Joseph Story* (1835 and 1852); Roscoe Pound, "The Place of Judge Story in the Making of American Law," *American Law Review*, 48:676-697 (Sept.-Oct. 1914); W. Schofield, "Joseph Story, 1779-1845," *Great American Lawyers*, ed. by W. D. Lewis, 3:123-185 (1908); Mortimer D. Schwartz and John C. Hogan (eds.), *Joseph Story* (1959). Constitutional developments during the period are evaluated in: Carl B. Swisher, *American Constitutional Development* (1943); and W. W. Crosskey, *Politics and the Constitution in the History of the United States*, 2 vol. (1953). (JN. C. H.)

**STORY, WILLIAM WETMORE** (1819-1895), U.S. sculptor and author, who is most famous for his statue "Cleopatra," was born in Salem, Mass., on Feb. 12, 1819. He graduated from Harvard College in 1838 and studied law under his father Justice Joseph Story. After his graduation from Harvard Law School in 1840 he decided while practising law in Boston to become a sculptor. In 1856 he settled in Rome and remained there for the rest of his life. He lived in the Palazzo Barberini, where he entertained famous literary, theatrical, and social figures of the day.

Story's "Cleopatra" was exhibited at the London Exposition in 1862 (a replica of it is in the Metropolitan Museum of Art, New York City). Nathaniel Hawthorne's description of this work in his novel *The Marble Faun* (1860) contributed greatly to its wide popularity in the United States and Great Britain.

In addition to his sculpture, Story wrote several volumes of poetry, essays, a biography of his father, and various legal works.

He died at Vallombrosa, Italy, on Oct. 7, 1895. Story's fame has been kept alive by the interest in Henry James's book about him titled *William Wetmore Story and His Friends* (1903; reprinted 1957).

See A. Gardner, *Yankee Stonecutters* (1945). (A. T. G.)

**STOSS, VEIT** (1438? or 1447?-1533), German sculptor whose style, developed from that of Nicholas Gerhaert, astonishes by its dramatic realism and emotional force no less than by the technical virtuosity of the carving. He was born in Swabia but reared in Nürnberg. From 1477 to 1496 he worked mainly in Poland, Bohemia, and Hungary. His principal works are the majestic high altar, carved in limewood and painted, of the German church, St. Mary's, in Cracow (1477-89) and the sculptured tombs of King Casimir IV and Archbishop Zbigniew Olesnicki in the cathedrals of Cracow and Gniezno. When he returned to Nürnberg, he was defrauded of his savings, attempted to regain them by forgery, was discovered and branded, and passed an embittered old age encumbered with civic disabilities. His work of this period includes important wood and stone sculpture in the churches of St. Sebaldus (1499, 1520) and St. Lorenz (1513, 1518) in Nürnberg, and a carved altar in Bamberg Cathedral (1523). He was active also as a painter and engraver. He died at Nürnberg in 1533.

See Eberhard Lutze, *Veit Stoss* (1938); Tadeusz Dobrowolski, *Wit Stwoss: Oltarz Krakowski* (1951). (D. Kc.)

**STOTHARD, THOMAS** (1755-1834), English subject painter, designer and book illustrator, was best known for his work in illustration. Born in London on Aug. 17, 1755, he was apprenticed in Spitalfields to a draftsman of patterns for silks and in 1777 became a student of the Royal Academy. He was elected associate in 1791 and full academician in 1794, being appointed librarian in 1812. He died in London on April 27, 1834.

In 1779 Stothard became a contributor to *Novelist's Magazine*

and to Bell's *Poets*. Because he was so ill-paid he supplemented his income by designing plates for pocket books, tickets for concerts, illustrations for almanacs, portraits of popular actors—and into even the slightest sketches he infused grace and distinction. He is at his best in domestic or ideal subjects; the heroic and tragic were beyond his powers. He began to exhibit pictures in oil at the Royal Academy in 1778 and continued to do so until his death. His oils are usually small in size and free in handling, but their colouring is often rich and glowing. His best-known painting is the "Canterbury Pilgrims," in the Tate gallery, the engraving from which attained immense popularity and heralds the methods of Pre-Raphaelitism.

Stothard illustrated many books, including *The Adventures of Peregrine Pickle*, *Clarissa Harlowe*, *Tristram Shandy*, *Robinson Crusoe*, *The Pilgrim's Progress*, *The Vicar of Wakefield*, *The Rape of the Lock* and the works of Shakespeare, Byron, Milton and other poets. He also decorated the mansions of many of his wealthy patrons. (D. C. T. T.; X.)

**STOUR**, an ancient river name used for five English rivers in Suffolk, Kent, Hampshire, Worcestershire, and Warwickshire. The Suffolk Stour measures 47 mi. (76 km.) from its sources in the Chalk ridge of Cambridgeshire. It flows eastward along the county boundary between Suffolk and Essex through country made famous by the artist John Constable. At Manningtree it becomes a broad, shallow tidal estuary, and 10 mi. beyond enters the North Sea at Harwich. The Great, or Kentish, Stour is 40 mi. (64 km.) long. After uniting eastern and western headstreams in the Weald at Ashford, it breaks through the North Downs in a deep scenic valley to Canterbury. Downstream it traverses a series of lagoons caused by gravel working and colliery subsidence. From there the river is tidal. Its floodplain is a silted marine inlet, which as the former Wantsum Channel separated the Isle of Thanet from the mainland until the 14th century. The main discharge is south of Thanet to Pegwell Bay, while a small distributary, the Wantsum, debouches into the North Sea near Reculver. The final loop of the Stour is 7 mi. in length, but only 200 yd. (183 m.) across the neck, where an artificial cut assists flood control. The river is navigated to Sandwich by small timber vessels. The other three Stours are mere tributary streams. (A. M. Co.)

**STOURBRIDGE**, a municipal borough (1914) in the Dudley parliamentary division of Worcestershire, Eng., 12 mi. (19 km.) W of Birmingham by road. Pop. (1961) 42,631. Stourbridge glass, dating from 1556, is still made in the district, and the college of further education teaches glassmaking. At the Council House in Mary Stevens Park is a permanent glass exhibition. King Edward School (1430) was attended by Samuel Johnson; Oldswinford Hospital (bluecoat) School was founded in 1667. Manufactures include hollow ware, refractories, chains, tools, and leathers.

**STOUT, GEORGE FREDERICK** (1860-1944), British psychologist and philosopher, powerful critic of associationism and forerunner of Gestalt psychology, was by far the most influential British psychologist of the early 20th century. He was born Jan. 6, 1860, at South Shields, Eng., and educated at Cambridge. He was appointed reader in mental philosophy at Oxford in 1898 and professor of logic and metaphysics at St. Andrews in 1903. He spent the last eight years of his life in Australia, and died in Sydney, New South Wales, on Aug. 18, 1944.

Stout approached psychology primarily from a philosophical standpoint. His best-known works, *Analytic Psychology* (1896), *Manual of Psychology* (1898), and *Mind and Matter* (1931), provided a systematic theory designed to supplant the associationism of the 19th century (see ASSOCIATION, MENTAL). He firmly rejected the Cartesian dualistic conception of body and mind and reverted to a biological concept not unlike Aristotle's idea of the soul as the form of the body (see BODY AND MIND). Stout anticipated many of the principles later developed by the Gestalt School and by psychoanalytic writers such as Sigmund Freud. See also CONSCIOUSNESS: *As a Relation*; GESTALT PSYCHOLOGY: *Antecedents*.

See C. A. Mace, *George Frederick Stout* (1948). (Cy. B.; X.)

**STOUT**: see BEER; BREWING.

**STOVE**: see HOME EQUIPMENT; HEATING AND VENTILATION.

**STOW, JOHN** (1525–1605), the best known of the Elizabethan antiquaries, author of a famous *Survey of London* (1598; revised and enlarged, 1603), was born of a London family of tallow-chandlers in 1525. He became a tailor (freeman of the Merchant Taylors' Company, 1547), and practised his trade until c. 1565–70, after which he devoted his time and money to collecting rare books and manuscripts. He had already published an edition of Chaucer (1561) and a useful *Summary of English Chronicles* . . . (1565; many abridged versions). His first original work was *The Chronicles of England* . . . (1580), revised as *Annals of England* . . . (1592).

Self-educated, and with a passion for learning, he became the friend of famous antiquaries, and was employed by Archbishop Parker to edit medieval chronicles. Prosperous as a tailor, he became poor, traveling everywhere on foot in search of records. After 1579 he had a small yearly pension from the Merchant Taylors', and in 1603 received letters patent to collect alms. He died in London on April 6, 1605.

The *Survey*, cast in the form of a "perambulation" round the London wards, contains fascinating detail of the life, customs, buildings, monuments, government, and people of London at a time of transition from medieval to modern, with an account of the city's origins and growth. Stow sought out those who could describe past beauties and customs, and drew material from City and church records, from monastic cartularies, from early chroniclers, and from his own lifelong observation and retentive memory. Though his lack of linguistic learning sometimes resulted in faulty interpretation, his *Survey* is a pioneer work of scholarly devotion by a great Londoner to the city he loved.

**BIBLIOGRAPHY.**—Some of Stow's manuscripts are at the British Museum, others at Lambeth Library. There were many 17th-, 18th-, and 19th-century "continuations" and editions of the *Survey*; the best modern edition is that from the 1603 text by C. L. Kingsford, 2 vol. (1908), *Additional Notes* (1927). There is a useful Everyman's Library edition (1965). See also the annual commemorative addresses given at St Andrew's Undershaft, London, published in the *Transactions of the London and Middlesex Archaeological Society*. (Jl. H.)

**STOWE, HARRIET ELIZABETH BEECHER** (1811–1896), U.S. writer and philanthropist, is famous as the author of *Uncle Tom's Cabin*. She was born at Litchfield, Conn., on June 14, 1811, the daughter of the clergyman Lyman Beecher (q.v.). After her mother's death in 1815, she came most directly under the influence of her eldest sister Catharine, who a few years later set up a school in Hartford, where Harriet was first a pupil and afterward a teacher. In 1832 her father, who had for six years been the pastor of a church in Boston, accepted the presidency of the newly founded Lane Theological Seminary at Cincinnati, O. Catharine went with him and established a pioneer college for women, the Western Female Institute. Harriet was an assistant at the school, taking an active part in the literary and school life, at the school, stories and sketches to local journals, and compiling a school geography, until the school closed in 1837. She was married Jan. 6, 1836, to one of the professors in the seminary, Calvin Ellis Stowe. In the midst of privation and anxiety, due largely to her husband's precarious health, she wrote continually, and in 1843 published *The Mayflower, or Sketches of Scenes and Characters among the Descendants of the Pilgrims*.

She lived 18 years in Cincinnati, separated only by the Ohio River from a slave-holding community, coming in contact with fugitive slaves and learning from friends and her own visits the life of the South. In 1850 her husband was elected to a professorship in Bowdoin College, Brunswick, Me., and moved his family there.

In Brunswick, Mrs. Stowe wrote, for serial publication in the *National Era*, an antislavery paper of Washington, D.C., the story of *Uncle Tom's Cabin; or, Life Among the Lowly*. The publication in book form (1852) was a factor which must be reckoned in summing up the causes of the Civil War. Her name was anathema in the South. The book sprang into unexampled popularity, and was translated into at least 23 languages; the dramatic adaptation was also immensely popular. Mrs. Stowe reinforced her story with *A Key to Uncle Tom's Cabin* (1853), in which she accumulated a large number of documents and testimonies against slavery and in defense of criticism of her accuracy. In 1853 when she

THE BETTMANN ARCHIVE

HARRIET BEECHER STOWE

made a journey to Europe she was lionized in England by people from all walks of life. (A magazine article published in 1869, "The True Story of Lady Byron's Life," detailing her charge that the poet had had an incestuous love for his sister, later turned British public opinion against her.) In 1856 she published *Dred: a Tale of the Dismal Swamp*, in which she threw the weight of her argument on the deterioration of a society resting on a slave basis. The establishment of the *Atlantic Monthly* in 1857 gave her a constant vehicle for her writings, as did the *Independent* of New York, and later the *Christian Union*, of which papers successively her brother, Henry Ward Beecher, was one of the editors.

She thereafter led the life of a woman of letters, writing novels, of which *The Minister's Wooing* (1859) is best known, and many studies of social life in both fiction and essay. Her *Pearl of Orr's Island* (1862) was credited by the U.S. writer Sarah Orne Jewett with having revealed to her the literary value of the country folk. Mrs. Stowe published also a small volume of religious poems, and toward the end of her career gave some public readings from her writings. In 1852 Calvin Stowe accepted a professorship in the theological seminary at Andover, Mass., and the family made its home there till 1863, when he retired and moved to Hartford.

After the close of the Civil War, Mrs. Stowe bought an estate in Florida, and she spent many winters there. After the death of her husband in 1886, she lived in the seclusion of her Hartford home, where she died on July 1, 1896. She is buried by the side of her husband at Andover.

**BIBLIOGRAPHY.**—The Riverside edition of Mrs. Stowe's works was published in 1899 and 1906 in 16 volumes (with an additional volume of biography). See also Annie Fields (ed.), *Life and Letters of Harriet Beecher Stowe* (1897); C. E. and L. B. Stowe, *Harriet Beecher Stowe: the Story of Her Life* (1911); F. Wilson, *Crusader in Crinoline* (1941); C. H. Foster, *Rungless Ladder: Harriet Beecher Stowe and New England Puritanism* (1954); and J. C. Furnas, *Goodbye to Uncle Tom* (1956). (H. E. S.; X.)

**STOWELL, WILLIAM SCOTT, BARON** (1745–1836), English admiralty judge, author of influential doctrines in international law, and brother of Lord Chancellor Eldon, was born on Oct. 17, 1745, near Newcastle upon Tyne. He was educated at the Newcastle grammar school and at Corpus Christi College, Oxford, from which he received his B.A. degree in 1764, his M.A. in 1767, his bachelor of civil law in 1772, and the doctor of civil law in 1779. He was an intimate friend of Samuel Johnson. He elected to practise in the admiralty and ecclesiastical courts and became advocate general for the office of lord high admiral in 1782 and in 1798 judge of the high court of admiralty. On the coronation of George IV in 1821, he was raised to the peerage as Baron Stowell. He died at Earley Court, Berkshire, on Jan. 28, 1836.

He stands in the front rank of English judges with Sir Matthew Hale and Lord Mansfield. His decisions in admiralty were the first of the English admiralty court to be published, and he was therefore free to be guided by writers on Roman, canon, and international law. His decisions were accepted by the United States courts through the work of Justice Joseph Story. The doctrines of international law with which the name of Lord Stowell are identified include: the perfect equality and entire independence of all states; the elementary rules of international law binding even semibarbarous states; the principles that a blockade, to be binding, must be effectual, and that a prize court is a court of the law of nations. (A. Dm.)

**STRABANE**, an urban district and market town of County Tyrone, Northern Ire., 14 mi. (23 km.) SSW of Londonderry by

road. Pop. (1961) 7,783. Area 2.9 sq.mi. (7.5 sq.km.). The Rivers Mourne and Finn join there to form the Foyle. Shirt and collar making is the chief industry, with flax spinning at Sion Mills village.

**STRABO** of Amasya in Pontus, Greek geographer and historian whose *Geography* is the only general treatise on the subject surviving from antiquity, was born c. 63 B.C. Of distinguished family, especially on his mother's side, Strabo was sent abroad at an early age to study under well-known teachers at Nysa in Caria, Rome and perhaps elsewhere. Later he lived for long periods in Alexandria and in Rome. It is not known where he finally settled. He boasts of having traveled more widely than any of his predecessors, "east to west from Armenia to the Tuscan region facing Sardinia, and north to south from the Black sea to the borders of Ethiopia." With the one major exception of a journey up the Nile c. 25 B.C. in the retinue of the governor of Egypt, Aelius Gallus, there are practically no details of these journeys and there is no idea of their purpose. Strabo seems to have kept to a few main routes: he had seen little of Italy, and in Greece he had visited Corinth and probably Athens, but not Delphi or Mycenae.

Strabo was a Stoic, and he wrote (as he tells us) for the instruction of educated statesmen and other readers of high station. His belief in the importance of history and geography to such men derives from Polybius, who influenced him profoundly. His main work—a *History* in 47 books, lost except for a handful of small fragments—after four introductory books continued Polybius' *History* at least down to Caesar's death. The *Geography*, probably a long appendix to this work, survives almost in full. The first two books form a general introduction, the next eight deal with Europe, the following six with Asia, the last with Africa (its shape and size totally misconceived). Since little is said about events after 7 B.C., the work was probably completed about that date. A few notes were added about A.D. 18–19, and there is one reference (added by an editor?) to an event of c. A.D. 23. But the work was never systematically revised.

Although Strabo defends the orthodox picture of a spherical universe centred in a spherical earth, both divided into five zones, and although, in discussing his predecessors' theories, he has much philosophical argument, he defines the geographer's proper task as "to describe the known parts of the *oikoumene*" (inhabited portion of the earth). He stresses the geographer's need for mathematical and scientific knowledge and makes extensive use of Hipparchus; but his own inclination is clearly toward descriptive and historical geography. His knowledge is chiefly gathered from books: his reading was wide and critical. His work shows little sense of order, except that imposed by the subject, and is full of historical and mythological excursions. His information is at best as good as that of his sources and can be far from recent: full of admiration for Homer, he bases his three books on Greece on Apollodorus' commentary on Homer's "Ships" catalogue."

The *Geography* had no influence on 1st-century writers. By the 6th century it was already a classic, and its reputation endured for centuries. To us its chief importance lies in the valuable source material (from Eratosthenes, Polybius, Poseidonius and others) that it transmits: without Strabo we could hardly begin to follow the development of ancient geography. The first good edition was by I. Casaubon (1587, revised 1620), by whose pages the text is normally cited. The Loeb edition (1917–32) by H. L. Jones with bibliography is very useful. The first volume (a general commentary) of a projected German edition by W. Aly, appeared in 1957. (E. BA.)

**STRACHAN, JOHN** (1778–1867), educator and first Anglican bishop of Toronto, whose principal achievement was to organize the church in Canada as a self-governing denomination within the Anglican communion, was born in Aberdeen, Scot., April 12, 1778. Educated at King's College, Aberdeen, he emigrated to Canada in 1799, was ordained (1803), and was appointed successively missionary at Cornwall, 1803; missionary at York (later Toronto), 1812; archdeacon of York, 1825; and bishop of Toronto, 1839. He fought a steady rear guard action to retain the privileged position of the church as a branch of the English es-

tablishment in the colony. As that position was gradually lost under colonial pressure, he created the first Anglican synod of clergy and laity in the British colonial empire (Toronto, 1851), raised endowment funds, subdivided his diocese, and presided over the first episcopal election by clergy and laity outside of the United States (1857). During his middle years he was a controversial political figure, as member of the Executive Council of Upper Canada after 1815, and as the power behind the ruling Tory clique. His political power waned with the granting of responsible government to the colony.

In 1827 he secured a royal charter for the University of King's College, Toronto, and served as its first president. When the foundation was secularized as the University of Toronto, he founded the University of Trinity College in 1852 as a church institution. His published works, about 30 in number, are largely polemical. (J. L. H. H.)

**STRACHEY, (GILES) LYTTON** (1880–1932), English biographer and critic, who revolutionized the writing of biography (q.v.), was born in London on March 1, 1880, the son of Sir Richard Strachey, the Indian administrator. He was at school in Derbyshire and at Leamington College, and studied history at Liverpool (1897–99) and at Trinity College, Cambridge (1899–1903). He then lived in London, writing for the *Spectator* and other reviews, and became a leading figure in the Bloomsbury group (q.v.).

In 1912 he published *Landmarks in French Literature*, and throughout his life he did much by his articles (collected in *Books and Characters*, 1922; and *Characters and Commentaries*, 1933) to make his countrymen appreciate the precision and delicacy of French poetry and prose. But his greatest achievement was in biography. He made his reputation with *Eminent Victorians* (1918) and *Queen Victoria* (1921) and added to it with *Elizabeth and Essex* (1928) and *Portraits in Miniature* (1931). Treating his subjects from a highly idiosyncratic point of view, he determined to create a work of art rather than a record of activities and events. He was fascinated by personality and motive and delighted in pricking the pretensions of the great and reducing them to somewhat less than life-size in a prose at once elegant, sinuous, and singularly ironical. His aim was to paint a portrait; and though this led to caricature and sometimes, through tendentious selection of material, to inaccuracy, he taught biographers a sense of form and of background, and he sharpened their critical acumen.

His many imitators lacked Strachey's detachment, taste, and Voltairean assurance. In his best work, *Queen Victoria*, he combined his gift for narrative with a power of analyzing characters with whom he had nothing in common. His defects as a biographer arose mainly from his limited vision of life. He did not love the past for its own sake; and he saw politics largely as intrigue, religion as a ludicrous anachronism, and personal relations as life's supremely important facet. Though bitterly attacked during his lifetime and after, Strachey remains a phenomenon in English letters and a preeminent humorist and wit. He died unmarried at Ham Spray House, near Hungerford, on Jan. 21, 1932.

See Sir Max Beerbohm, *Lytton Strachey* (1943); R. A. Scott-James, *Lytton Strachey* (1955). (N. G. A.)

**STRADELLA, ALESSANDRO** (c. 1645–1682), Italian composer, singer, and violinist. The facts about his life are surrounded by mystery and much legend. He apparently lived for periods in Modena, Venice, Rome, and Florence in, as E. Allam says, "a kind of uncharted territory between the amateur and professional worlds." In Turin in 1677 an attempt was made to murder him, for reasons that are not definitely known, though it was believed to be at the instigation of a Venetian senator with whose fiancée Stradella had eloped. On Feb. 28, 1682, there was another successful attempt on his life.

Stradella was one of the finest composers of chamber cantatas of which he wrote more than 200; his fresh, mellifluous melodies are frequently supported by harmonies bolder than are usually found in music of this period. His instrumental music, both chamber and orchestral, is also worth reviving; particularly interesting is his novel application of *concerto grosso* texture to accompaniments of arias in some of his stage works and oratorios. But a

the whole his dramatic works are not distinctive.

Stradella's legendary life, embroidered from suspicion and exiguous facts, was the subject of eight 19th-century operas and of at least one novel. (N. Fo.)

**STRADIVARI, ANTONIO** (?1644–1737), Italian violin maker, was associated throughout his life with the city of Cremona, where he brought the craft of violin-making to its highest pitch of perfection. He was still a pupil of Nicolo Amati in 1666, when he had begun to insert his own label on violins of his making. These at first followed the smaller Amati model, solidly constructed, with a thick yellow varnish. In 1684 he began to produce larger models, using a deeper-coloured varnish and improving the craftsmanship in many ways. His "long" models, dating from 1690, represent a complete innovation in the proportions of the instrument; while from 1700, after returning for a few years to an earlier style, he again broadened and otherwise improved his model. He also made some fine cellos and violas. The Stradivari

method of violin-making created a standard for subsequent times; but the secret of his varnish, soft in texture, and shading from orange to red, though much debated, has never been discovered. He died at Cremona on Dec. 18, 1737.

Stradivari's sons **FRANCESCO** (1671–1743) and **OMOBONO** (1679–1742) were also violin-makers. They are believed to have assisted their father, probably with Carlo Bergonzi, who appears to have succeeded to the possession of Antonio's stock-in-trade.

**STRAFFORD, THOMAS WENTWORTH, EARL OF** (1593–1641), English statesman, attempted to consolidate the sovereign power of Charles I by the so-called policy of "thorough," but was ultimately sacrificed by the king to appease Parliament. He was born in London on April 13, 1593, the eldest surviving son of Sir William Wentworth, a wealthy Yorkshire landowner. Educated at St. John's College, Cambridge, and at the Inner Temple, he was knighted by James I in 1611. His marriage to Lady Margaret Clifford, daughter of the impoverished earl of Cumberland, established a link with an ancient and noble family still influential in the north. Shortly after his marriage he completed his education by a leisurely journey through France, returning to England shortly before his father's death in 1614.

For the next years his conduct followed the familiar contemporary pattern for a young man of wealth and local influence seeking to make a career at the national level through court and Parliament. He represented Yorkshire in the Parliaments of 1614 and 1621, and Pontefract in 1624. In Yorkshire he was appointed *custos rotulorum* (keeper of the rolls) in 1615, an office which he refused to vacate two years later to make way for his powerful neighbour Sir John Savile, thus starting a personal feud which dominated Yorkshire politics for the next decade.

In the Parliament of 1621 his local influence secured the election as the other member for Yorkshire of the court candidate, the secretary of state Sir George Calvert, a service for which he received no special thanks from the court. In Charles I's first Parliament (1625) Wentworth, who was now resentful of the court and critical of the all-powerful favourite, George Villiers, first duke of Buckingham (q.v.), was again returned for Yorkshire. His election was challenged by Savile; Parliament decided in Wentworth's favour but not before he had been violently denounced in the

House of Commons by Sir John Eliot for attempting to take his seat while his case was still under discussion.

Meanwhile, his first wife had died childless (1622) and he had married Arabella Holles, daughter of John, earl of Clare, a peer out of favour at court who brought Wentworth into touch with the critics of the king's and Buckingham's expensive and inefficient policy of war against Spain—and from 1627 against France. Along with other critics of the court he was prevented from sitting in the Parliament of 1626, having been appointed sheriff of Yorkshire in 1625; later in the year he refused to subscribe to the forced loan, imposed to pay for the war, and was for some time under arrest.

In the Parliament of 1628 he was one of the leading critics of crown policy in the Commons and advocated the measure in defence of the rights of the subject which was subsequently passed as the Petition of Right. But he did not join in the attack on Buckingham stimulated by Eliot in the last part of the session. During the recess he was approached by the court, now anxious to repair past neglect and to buy back his support, with the offer of a barony. Wentworth accepted. In December he was appointed lord president of the north, virtually governor of England north of the Humber. In the following year (1629) he was given a seat on the Privy Council.

Wentworth's return to the service of the court, coming so soon after his vehement opposition to it in Parliament, startled even some of his closest friends. His conduct was no doubt partly inspired by personal ambition, though he had logical reasons for his change of front since in the summer of 1628 the king gradually abandoned his war policy. The murder of Buckingham in August of that year made way for more sober policies in future. Though he certainly wanted power and the material fruits of office, Wentworth also had a vision of better government and there is no reason to doubt the sincerity of his claim, in his first speech as president of the north, that he came to serve his countrymen as "an instrument for good."

On the council Wentworth seems to have advocated the paternalist government which distinguished the early years of the king's personal rule; closer supervision of justices of the peace, more effective implementation of the poor law, of laws against enclosure, and of measures for dealing with famine, though he was not above privately making profit out of the corn shortage of 1631. As lord president of the north he quelled all defiance of his authority and made many enemies by his insistence on the honour due to him as the king's representative, but his administration was on the whole just and efficient; he supervised the local justices, curbed the often tyrannous excesses of local magnates, and, in the bad plague year of 1631, behaved conspicuously well at York. In the same year he was deeply distressed by the death of his much-loved wife, though he provoked scandalous rumours not long afterward by secretly marrying (October 1632) Elizabeth Rhodes, the young daughter of a neighbouring squire.

The king meanwhile had appointed him lord deputy of Ireland. Taking up his office in the summer of 1633, he immediately set himself to consolidate the royal authority, to break the power of the dominant clique of "new English" landowners, to extend English settlement, improve methods of agriculture, increase the productivity of the land, and stimulate industry and trade. His ultimate goal was to assimilate Irish law and customs to the En-

BY COURTESY OF EARL FITZWILLIAM

"FIRST EARL OF STRAFFORD WITH A WOLFHOUND," PAINTED BY SIR ANTHONY VAN DYCK, 1636

lish system and to make a prosperous Protestant Ireland into a source of revenue to the English crown. He made great use of the prerogative Court of Council Chamber to enforce his will and it may be that in this, as also in his masterful control of the Irish Parliament, he was consciously setting an example of the type of government that he hoped the king would achieve in England.

He was by this time on terms of close friendship with William Laud, archbishop of Canterbury, with whom he discussed his policy in a regular and very full correspondence. Between them they used the word "thorough" to describe the reformed efficient administration they wished to create.

Wentworth's policy in Ireland seemed at first successful. He cleared the sea of pirates, while the newly established conditions of peace with Spain were favourable to Irish trade. He took over personally the administration of the customs and greatly increased the revenue. He made some good appointments to the Irish bench. He established the king's right to settle the province of Connaught. He compelled the earl of Cork and other unscrupulous landowners to disgorge church property wrongfully appropriated. He created a small efficient army. He reformed Trinity College (to which he sent his son) and founded the first theatre in Dublin. But his methods were ruthless and at times unscrupulous. He alienated the Irish by extending English settlement, and the English by undermining their influence and interfering with their gains.

Although he greatly increased the revenues of the crown, he lost no opportunity of enriching himself, and his immense fortune laid him open to criticism. To get the administration of the customs into his own hands he eliminated the vice-treasurer, Lord Mountnorris, by trying him for treason before a court-martial, and he arrested the lord chancellor in full council. His conduct was criticized by his victims who had friends at court in England; the king did not always support him against them and even Archbishop Laud occasionally expressed doubts in his private letters.

In 1639, after the abortive attempt of King Charles to force episcopacy on Scotland and his defeat in the First Bishops' War, Wentworth was recalled to England for advice. He recognized that the Scottish revolt was a critical challenge to the king's authority and he advised the calling of Parliament which he believed by skilful management could be made to vote supplies for a war on Scotland. He guaranteed that the Irish Parliament would do so. Created earl of Strafford early in 1640, he returned to Dublin where he secured unqualified parliamentary support for the king. But on his return to London he found the English Parliament recalcitrant and had to vote with the rest of the Privy Council for its dissolution (May 1640). The disastrous Second Bishops' War followed. Though extremely ill, Strafford took command of the English army but failed to prevent the Scots from overrunning the northern counties. The king, unable to pay his own troops or to buy off the Scots, was compelled by joint English and Scottish action to call a new Parliament in November 1640.

Strafford was the chief target of attack from both nations. He was advised to leave the country, but the king relied on his help and assured him that he should not suffer in life or fortune. Detained by illness, he reached Westminster on Nov. 10 with the intention of impeaching the king's opponents in Parliament for treasonable correspondence with the Scots. The leader of the Commons, John Pym, acted first, by impeaching Strafford before he could take his seat in the House of Lords. His trial began in March 1641. The basic accusation was that of subverting the laws, supported by a charge that he had offered to bring over the Irish Army to subdue the king's opponents in England. More detailed charges rested on his administration in Ireland and the north. He conducted his defense with great skill and it looked at one time as though he might be acquitted. Pym therefore introduced a Bill of Attainder (*i.e.*, a summary condemnation to death by special Act of Parliament). The Commons passed it by a large majority, the Lords, intimidated by popular rioting, by a much smaller one. While an angry mob surged round Whitehall, Strafford wrote to the king releasing him from his promise of protection, and Charles, afraid for the safety of the queen, gave his

consent to the bill. Strafford went to the scaffold on May 12, 1641, in the presence of an immense and jubilant crowd. In his last speech he once more professed his faith in "the joint and individual prosperity of the king and his people," for which, in his view, he had always worked.

He remains an enigmatic figure in English history, ambitious, greedy for power and wealth, ruthless, and sometimes dishonest, but with a vision of benevolent authoritarian government and efficient administration to which he often gave persuasive expression. He made innumerable enemies but his few close friends were deeply attached to him; he was a generous master to his servants, a good husband, and an indulgent father. In the last weeks of his life his dignity, eloquence, and loyalty to the king made a deep impression even on some of his enemies. Among Royalists he was subsequently elevated to the position of proto-martyr for the royal cause.

**STRAIN GAUGE.** The strain gauge has many scientific applications, particularly in engineering. In addition to the measurement of strain, the gauge has been applied as a transducer to determine magnitudes of forces, torques, pressures, accelerations and similar physical quantities. This wider application has resulted from the development of a gauge using electric phenomena, but mechanical and optical magnification are also employed to measure strain. If loads are applied to materials such as metals or glass, the deformations usually are not discernible to the eye. The function of a strain gauge is to magnify the small deformations on the surfaces of mechanical parts or structures to the point where they can be measured.

FIG. 1.—STRAIN GAUGES SHOWING CONSTRUCTION

In engineering, normal strain is defined as the deformation in a given direction divided by the gauge length in the same direction. If a 2 in. length, called the gauge length, is marked on a piece of rubber thread, it can be made to increase perceptibly when the thread is stretched. If the forces are such that the original length has increased to 2½ in., the total deformation obviously is ½ in., and the strain is ¼ in. per inch. The strain has the same value throughout the length of the rubber strip for a given force, regardless of the gauge length used, and increases as the force becomes greater.

If a block is shortened under a compressive load, compressive strains are developed. In parts of irregular shape which may be subjected to more complicated loading systems, the strain may vary from point to point, and a short gauge length therefore is required.

Engineers are interested in regions of high strain on parts or structures. If strains are known, properties of the material may be used to compute stresses, which are defined as forces per unit area. Conversely, if stresses are known, strains can be calculated. In design, mathematical equations are used to proportion the parts of a machine or structure so that the stresses caused by the applied loads are within the allowable limits of the materials specified. Strain gauges are applied to the actual structure or part to check these mathematical computations or to determine the strains at points when it is difficult or impossible to compute them.

One type of strain gauge widely used for this purpose is the bonded electric resistance strain gauge developed in 1938. The gauge consists of a length of fine wire, 0.001 in. in diameter

formed into a grid as shown in fig. 1 and cemented between two pieces of thin paper. Small and light, the gauge is made in many types, mostly in the size of a postage stamp. Gauge lengths as short as  $\frac{1}{8}$  in. are available. The gauge is cemented to the part being tested. Many different cements have been used. As the part is loaded, the wire grid faithfully follows the deformations under it, either in tension or in compression, and the length and cross sectional area of the wire are changed. This causes the electrical resistance of the wire to change; even though this change is small—often a fraction of an ohm—electric circuits and instruments are available to detect the variation. A simple relation called the gauge factor exists between the unit change in resistance and the strain. This relation may be expressed mathematically by

$$\text{gauge factor} = \frac{\Delta R}{R} / \frac{\Delta L}{L} \quad (1)$$

where  $\Delta R$  is the change in resistance caused by strain,  $R$  is the original resistance of the gauge, and  $\Delta L/L$  is the strain under the grid.

The manufacturer supplies the value of the gauge factor and the original resistance of each lot of gauges. If  $\Delta R$  or a voltage change proportional to it is then measured, the strain can easily be calculated. The gauge is sensitive enough to detect strains as low as 0.000001 in. per inch and to measure strains as high as 0.03 in. per inch; special types can measure strains three times this value.

A gauge in which the grid is formed from metallic foil has been used to measure strains at temperatures as high as 1200° F.

Advantages are readily apparent. Many gauges have been bonded to structures and parts at strategic spots and their behaviour under load reported by wires leading to electronic instruments far removed from the test spots. Dynamic or rapidly changing strains occurring for example in freight car couplings or rocket firings have been recorded by oscilloscopes which handle strain variations as high as 50,000 cycles per second.

Strain gauges are used for measuring quantities other than strains. Load cells of various designs have been developed to measure force. Gauges have been bonded to short steel cylinders, the output of the gauges being calibrated in terms of the forces applied to them. Cells with capacities as high as 3,000,000 lb. have been built by the U.S. bureau of standards and calibrated in terms of force with an accuracy of 0.1%. Cantilever load beams have also been designed for force measurements. Gauges have been bonded to diaphragms, and the pressures on the diaphragms—static or variable—have been measured and recorded. Many other applications of the gauge have been made, especially to the measure-

FIG. 3.—TUCKERMAN OPTICAL STRAIN GAUGE

ment of accelerations. Other types of electric gauges—the unbonded resistance, electric inductance and electric capacitance gauges—have been utilized for the purposes described above.

Since 1870, many different types of instruments have been developed using a compound lever system for magnifying strains. The Huggenberger Tensometer shown in fig. 2 is of this type. The gauge length on most models is  $\frac{1}{2}$  in. or 1 in., and magnifications of 1,200 to 1 are common. These instruments have been used to measure static strains with reliable accuracy. Their chief disadvantages are large size and inability to respond to dynamic strains. Other gauges employing levers, or levers and dial indicators, are the Whittemore, Berry and Porter-Lipp gauges.

The Tuckerman optical strain gauge was designed to use a beam of light as an optical lever for magnifying deformations. The gauge consists of an extensometer and an autocollimator as shown in fig. 3. The extensometer has a fixed knife-edge and a pivoted lozenge which are brought into contact with the part undergoing deformation. A one-inch gauge length is shown. One side of the Stellite lozenge is ground and lapped to an optically flat mirror surface. The autocollimator houses an optical system which can be adjusted above the gauge and is so designed that its distance above the extensometer is not critical. A beam of light from a lamp in the autocollimator is directed upon a prism in the extensometer, then reflected to the mirror surface of the lozenge and back to a graduated scale in the autocollimator. As the lozenge rotates, the reflected light beam from its mirror surface moves across the scale and may be viewed through an eyepiece in the autocollimator. The smallest deformation measurable is 0.00005 in. and for a gauge length of 1 in. this corresponds to a strain of 0.000005 in. per inch. The accuracy of the gauge is excellent, and it has therefore been regarded as a basic instrument for strain measurement.

Strain gauges of the types described above have been used in research laboratories and test stands of many companies, large and small, and in the control of manufacturing processes in refineries, steel mills and chemical industries.

See ELASTICITY.

**STRAITS AND INTEROCEANIC CANALS.** In the geographic sense, a strait is a narrow stretch of the seas separating two land areas and linking two portions of the seas or a gulf with the high seas. In the legal sense, however, a strait is a point between two stretches of the high seas at which the territorial seas of two land areas meet and overlap. Since various states claim territorial seas ranging from three miles upward, it is impossible to fix a single generally accepted maximum breadth for a strait. A strait connecting the high seas with a gulf having one or more littoral states (such as the Straits of Tiran forming the entrance to the Gulf of Aqaba) is generally but not universally treated in the same way as a strait connecting two stretches of the high seas. Although interoceanic canals have occasionally been referred to as "artificial straits," they are not subject to the same legal regime as straits; their narrowness, length, and artificial character set them apart. Canals that connect two seas but are used for local traffic and are not traversed by large seagoing vessels (such as the Baltic-White Sea Canal in the U.S.S.R. or the Gota Canal, connecting the North Sea and the Baltic) are not of international significance.

**Straits.**—Approximately 30 straits are considered important routes for international traffic. Under customary international law, as enunciated by the International Court of Justice in the Corfu Channel case (1948), both merchant ships and warships have, unless otherwise prescribed by treaty, a right of free passage "through straits used for international navigation between two parts of the high seas without the previous authorization of a coastal state, provided that the passage is *innocent*." Save in this respect, the Geneva Convention of 1958 subjects the territorial sea in straits to the same regime as the territorial sea elsewhere. In time of war, a neutral littoral state may enforce reasonable mea-

asures to protect the neutrality of its territorial waters within a strait. Such measures may include the laying of mines and compulsory pilotage, but the strait must be kept open to free navigation. When a coastal state is at war, it may close the strait to enemy shipping and vessels carrying contraband to the enemy and may take all belligerent measures that it would be authorized to employ in its other territorial waters or on the high seas. Because of exceptional geographical and political circumstances, passage through certain straits is restricted by treaty. The most notable instance of such regulation is the Montreux Convention of 1936, which controls the passage of warships and merchant vessels through the Turkish straits and permits the closing of the straits when Turkey is at war. (See STRAITS QUESTION.)

**Interoceanic Canals.**—In the second half of the 20th century the three major interoceanic canals—Suez, Panama, and Kiel—were operated and maintained by the states with jurisdiction over the territory through which the canals passed. The three were opened to common usage by treaties that dedicated them to free navigation by the ships of all nations on a nondiscriminatory basis. Freedom of navigation through the Suez Canal was secured by the Convention of Constantinople of 1888 and was reaffirmed by the Egyptian government in its declaration of April 24, 1957; through the Panama Canal by the Hay-Pauncefote Treaty of 1901 between the United States and Great Britain, and the Hay-Bunau-Varilla Treaty of 1903 between the United States and Panama, giving the United States a permanent lease of the Canal Zone; and through the Kiel Canal by the Versailles Treaty of 1919. So long as the administering state is not at war, these canals must be left open to navigation by the warships and merchant ships of all nations. The passage of the shipping of belligerents is not, in the view of the Permanent Court of International Justice in the case of the SS "Wimbledon," inconsistent with the neutrality of the nation operating the canal. The treaties governing the Suez and Panama canals forbid belligerents using the waterways to take hostile measures in the canals or their approaches. The Panama Canal is the only one expressly "neutralized" by treaty, but all three have been fortified and defended by the powers in control of the adjacent territory when those nations have been at war. In case of a war to which the proprietor nation is a party, an interoceanic canal may be closed to enemy vessels and ships carrying contraband to the belligerents. The United Nations, however, condemned Egypt's closure of the Suez Canal to Israeli ships and cargoes on the ground that war could not lawfully exist between members of the United Nations. Passage through canals is at all times subject to the payment of tolls, but they must be equal for all states. They are fixed by the proprietor state, which assumes responsibility for the operation and maintenance of the waterway.

See Erik Brül, *International Straits* (1947); R. R. Baxter, *The Law of International Waterways: With Particular Regard to Interoceanic Canals* (1964).

**STRAITS QUESTION.** The straits question concerns the international status of the Black sea straits, i.e., the Bosphorus and the Dardanelles, which form the only existing passage from the Black sea into the Mediterranean and vice versa. In 1453 these straits became a part of Turkey and thus entered into the eastern question (*q.v.*) until the end of the Ottoman empire in 1920. It is not identical with the problem of Constantinople as the former capital of the Byzantine empire, although the two problems might have been connected in the past. Whatever the political aspirations of the antagonists of the Ottoman empire, including Peter the Great, there was no straits question before 1774, for until then the Black sea was an inland Turkish sea. From 1774 on, with Catherine the Great acquiring the northern shore of the Black sea, the straits question appeared, involving the interests of Russia, Turkey and the non-Black sea naval powers. These interests did not coincide: Russia's aim was to secure free passage for its warships through the straits but to close them to warships of non-Black sea powers; the latter, and especially Great Britain with its imperial lifeline, aimed at keeping the Russian navy from entering the Aegean sea, or at least at opening the straits to the warships of all nations. The Ottoman empire, resisting both pressures, saw in the control of the straits a guarantee of its independ-

ence and security, and this point of view remained that of the Turkish republic. From 1947 the control of the straits by Turkey was also considered as a major guarantee of their own security by the non-Black sea powers.

The history of the straits question can be divided into three periods: (1) 1774–1841; (2) 1841–1920; and (3) after 1921.

**1774–1841.**—This period begins on July 10 (old style; July 21, new style), 1774, with the treaty of Kuchuk Kainarji (a village near Silistra, Bulg.) between Russia and Turkey, which inaugurated an epoch of bilateral Russian-Turkish agreements as to the straits. The treaty opened the Black sea and the straits to Russian commercial navigation, and this privilege was extended to the commercial navigation of other states by the peace treaty of Adrianople in 1829. Thereafter the principle of free commercial navigation in time of peace was not challenged by Turkey. Important for the economic development of south Russia, it did not conflict with the economic interests of the non-Black sea powers either. Russia pressed, however, for naval privileges; and Turkey, yielding in 1833, promised by the treaty of Unkiar Skelessi to close the straits on Russia's demand to warships of all non-Black sea powers. In 1840 the international situation prompted Nicholas I to look for a common action with Great Britain in Turkey; the treaty of 1833 was canceled by the London convention of July 13, 1841, which established a rule that no non-Turkish navy might cross the straits in peacetime.

**1841–1920.**—The London convention was the first general international convention concerning the straits, and it inaugurated a period in which they became the common concern of all great powers. The regime of the straits agreed upon in the London convention remained without modification until World War I. The prohibition of passage for warships of all nations was confirmed in 1856 (treaty of Paris), in 1871 (treaty of London) and in 1878 (treaty of Berlin). During the Bosnian crisis of 1908–09 Russia attempted to get a straits' regime more favourable to the passage of its warships, but in spite of Russia's political alignment with France and England in European affairs at that time, the attempt ended in a failure. During World War I, Turkey having fought on the side of the Central Powers, the Allied Powers agreed to the inclusion of the straits, after the war, in the Russian empire (treaty of London, 1915). However, the leaders of the October revolution having canceled all the imperial secret treaties and renounced all annexations, the problem of the straits was solved after the war differently and without the participation of Russia. The peace treaty of Sèvres (1920), which never went into force would have imposed on Turkey the disarmament of the straits and their opening to all foreign warships, while the zone of the straits would have passed under the administration of an international commission.

**After 1921.**—The proposed regime of the treaty of Sèvres was disrupted by the opposition of the national Turkish government formed by Mustafa Kemal. Thereafter, a forceful Turkish factor was increasingly influencing the straits question. In the beginning, since both Turkey and Soviet Russia were opposed to the treaty of Sèvres, the two powers agreed bilaterally that the problem of passage of warships should be decided by a conference of the Black sea states only (treaty of March 16, 1921). However, no such conference was held, and the regime of the straits was finally decided with the participation of the western powers at Lausanne (convention of July 24, 1923). The convention of Lausanne maintained the demilitarization of the straits and the freedom of passage for warships "under any banner"; also the International Commission of the Straits was maintained under the chairmanship of Turkey—a concession, among others, to Turkey. The convention included a clause that no naval force larger than the largest Black sea fleet might be sent in peacetime into the Black sea by a non-Black sea state.

Because this arrangement satisfied neither Turkey nor Soviet Russia, it was revised at Montreux on July 20, 1936, when a new international situation resulting from a more aggressive German and Italian policy made it appear dangerous also to Great Britain and France. The Montreux conference re-established the full right of Turkey to fortify the straits and disbanded the Interna-

tional commission. Reaffirming the already traditional freedom of navigation for commercial ships of all nations, the Montreux convention agreed to differentiate between the warships of Black sea states and those of non-Black sea states, giving to the former privileges the latter did not receive. With the exception of aircraft carriers and submarines, all warships of Black sea states were allowed to cross the straits unrestrictedly in peacetime; only light warships of non-Black sea states had this right under limitation of tonnage, number of units simultaneously present and duration of cruising time. In time of war the straits would be closed to all participants in the conflict if Turkey was neutral.

The Montreux convention (*q.v.*) was scheduled for revision in 1956 but the signatories were unable to agree on the premises of such a revision. In 1945 at Potsdam it was decided that each of the Big Three would communicate its views directly to Turkey concerning this revision. The U.S.S.R., although it had made demands on June 22, 1946, for joint control of the straits with Turkey, Great Britain and the U.S., backed Turkey in rejecting these demands as inconsistent with its independence and endangering its security. On May 30, 1953, the U.S.S.R. withdrew its demands of 1946.

**STRAITS SETTLEMENTS**, originally the collective name of four trading emporia, Penang, Singapore, Malacca, and Labuan, established or taken over by the English East India Company. Penang was founded by Francis Light in 1786, Singapore by Sir Thomas Stamford Raffles in 1819; Malacca, after temporary occupation by the British during the Napoleonic Wars, was finally transferred to the East India Company in 1824. These three territories were established as a crown colony in 1867. Labuan, which became part of Singapore Settlement in 1907, was constituted a fourth separate settlement in 1912.

The Straits colony ceased to exist in 1946. Labuan was incorporated in North Borneo (later Sabah), with which it became a part of Malaysia in 1963. Penang and Malacca were included in the Malayan Union (1946), the Federation of Malaya (1948), and Malaysia (1963). Singapore became a separate crown colony in 1946, attained full internal self-government in 1959, and became in 1963 a part of Malaysia, from which it was separated on mutually agreed terms in 1965 to become an independent republic.

(G. G. T.)

**STRALSUND**, a regional capital of East Germany in the *Bezirk* (district) of Rostock, German Democratic Republic. Pop. (1964) 67,888. The town, which is surrounded by water, is on the Strelasund, a strait between the mainland and Rügen Island. It is about 50 mi. (80 km.) NE of Rostock town by rail, and lines from Berlin and Rostock pass through it to the bathing and recreational centres on Rügen Island. The Rügen causeway connects Stralsund with the island. Fishing boats are built there; manufactures include fish-processing machinery, pipelines, furniture, sugar, and conserves; and there is fish smoking and brewing.

Stralsund received its municipal charter in 1234. The town was one of the leading members of the Hanseatic League. During the Thirty Years' War it was unsuccessfully besieged in 1628 by Wallenstein. After the Peace of Westphalia of 1648 it was transferred to Sweden; in 1815, after being occupied by France in 1807 and Denmark in 1814, it passed to Prussia. Although much damaged during World War II, it still retains its medieval centre, with Gothic buildings.

**STRANG, JAMES JESSE** (1813–1856), dissident Mormon leader, founder of the Strangite sect, a minute fragment of which still survives, was born at Scipio, N.Y., March 21, 1813. Admitted to the bar, he also taught school, edited a weekly paper, and was a country postmaster, before he followed his wife's family to Burlington, Wis., in 1843. Through his wife's brother-in-law,

a Mormon, he visited Joseph Smith at Nauvoo, Ill., became a Mormon convert, and was ordained an elder by Smith in February 1844. After Smith's assassination, Strang exhibited a letter, purportedly written by Smith and naming Strang, a Mormon of less than five months' standing, as his successor. He also claimed to have had a vision appointing him "seer, revelator, and prophet" of the Mormon Church. He was out-generated, however, by Brigham Young, and the Twelve Apostles denounced him as an impostor and forger and expelled him from the church. With a few of his 2,500 followers—one of whom was Joseph Smith's brother William—he moved to Voree (Vorhee, Vorree), Wis., where he caused himself to be crowned King James I after translating (with the aid of magic spectacles given him by an angel) *The Book of the Law of the Lord* from golden plates from the Ark of the Covenant. In 1849 the Strangites moved to Beaver Island, in Lake Michigan (40 mi. [64 km.] W of the Straits of Mackinac), and Strang received another revelation in the "plates of Laban." Under its rules polygamy was sanctioned, and he was married to four wives. The Strangites were the object of much persecution, but Strang was able to preserve the sect and to gain acquittal in the several lawsuits brought against him. He had more than 5,000 followers in Michigan and Wisconsin when he was shot on June 16, 1856, by two former Strangites. He was taken to Voree, where he died July 9, 1856. The Lake Michigan fishermen drove more than 2,000 of his believers from their homes and all but extinguished the Strangite branch of the Mormon Church.

**STRANRAER**, a royal and small burgh and seaport of Wigtown, Scotland. Pop. (1961) 9,250. It is situated at the head of Loch Ryan, an arm of the North Channel (Irish Sea), 52 mi. SSW of Ayr by road. It lies 39 mi. E by N of Larne in County Antrim, Northern Ireland, with which there is regular communication by mail steamer. Grain milling and nursery gardening are carried on, and there is a large trade in farm and dairy produce. Whitefish and herring are caught and there are oyster beds at Cairn Ryan on the east side of the loch. Stranraer, originally called St. John's Chapel, became a burgh of barony in 1596 and a royal burgh in 1617. In the centre of the town are the ruins of the castle of the 15th century, occupied for a time by John Graham of Claverhouse, Viscount Dundee, when he held the office of sheriff of Galloway (1682).

Three miles east of Stranraer is Lochinch, the residence of the earl of Stair, a modern structure (1870) in the Scots baronial style. The grounds include the White and Black lochs, and the ruins of Castle Kennedy on the isthmus between. This castle was erected in the reign of James VI for the earls of Cassillis, passed into the hands of the Stair family in the 17th century, and was burned down in 1716. The gardens, which contain the finest pinetum in Scotland, were restored in the middle of the 19th century.

**STRAPWORK**, in architecture and the decorative arts, a form of ornament developed in Germany, Flanders, and England during the latter half of the 16th and the 17th centuries and consisting of scrolls, straight lines, rectangles, and shield forms carved or modeled in flat relief, often with a raised fillet at the edge, and often pierced with circular or oval holes; the whole composition is usually formed of connected units, all upon the same plane, as though made by an elaborately cut out and pierced strap applied to a background. It is a development of certain Italian early Baroque motives, such as the multiple shield or cartouche frames, and certain approximations of it occurred in Italian metalwork as early as the silverwork of Benvenuto Cellini (1500–71); these forms are, themselves, Italian interpretations of the flat scrolls so common in Islamic metalwork. Strapwork was used extensively in the Renaissance woodwork of Germany and is occasionally found in stone, as in the Salzhaus at Frankfurt am Main (end of the 16th century). In Flanders and the Netherlands strapwork received an even more complete development, for although in Germany it was usually only a subsidiary motive, in the architectural woodwork and furniture of the Low Countries it often became the only type of ornament used. The form was introduced into England by the flood of Flemish and German woodworkers that came in in the latter part of the 16th and early 17th centuries. (T. F. H.)

**STRASBOURG**, a city of France and *préfecture* of the *département* of Bas-Rhin and of the region of Alsace (set up in 1964), lies 2 mi. (3 km.) W of the Rhine River, on the frontier between France and Germany. Pop. (1962) 225,964.

The city grew on an island between two branches of the Ill River. The Cathedral of Notre-Dame (11th–15th centuries) shows different styles, from Romanesque to late Gothic: the Romanesque crypt dates from 1015, the apse is Transitional, and the rest of the building Gothic. The cathedral is often considered to be typically German in style, but it was strongly influenced by French architecture, and the most strikingly German characteristic is probably its low proportions: for example the nave, completed in 1275, has a height of 107 ft. (32.6 m.) to a width of 53½ ft. (16.3 m.). The facade, with its rose window, was started about 1260 and not completed until much later. It is the work of several architects, but despite inconsistencies in its plan it has been much praised, notably by Goethe. It is asymmetrical, the north tower being completed by a remarkable 15th-century spire. At the entrance to the north transept is the Portal of St. Lawrence (1495–1505), designed by Jacob of Landshut. Many of the sculptures from the cathedral have been replaced by copies and some of the originals may be seen in the Maison de l'Oeuvre Notre-Dame. Near it is the Palais Rohan (1730), a former episcopal palace which houses three art museums. Also in the centre of the city are the Protestant Church of St. Thomas (13th–14th centuries), the Hôtel de Ville (1730–36), and the Chambre du Commerce (1582).

Strasbourg is a university city with an academy of music, and the headquarters of the Council of Europe. It is at the crossroads of routes from France to Central Europe and from the Netherlands to Italy, and it is linked by rail with Paris, Vienna, Berlin, Amsterdam, and Warsaw. There is an airport about 7 mi. (12 km.) from the city centre. The river port lies east of the city, on the Rhine, and by the mid-1960s dealt with well over 6,000,000 tons of traffic annually. From the port the Rhine is linked by canals with the Marne and the Rhône rivers. Many varieties of goods pass through the port including coal, food, wood, and metallurgical products. There are two modern petroleum refineries. Industries of Strasbourg include metallurgy, the manufacture of man-made textiles, tanning, brewing, food processing, and printing. Gutenberg made early experiments in printing there in 1436. The city's most celebrated product is *pâté de foie gras*.

Strasbourg has always been a place of great strategical importance. Originally a Celtic settlement, it was known to the Romans as Argentoratum. In the 4th century A.D. it was invaded by the Alamanni and in 357 it was the scene of a battle between the emperor Julian and the German tribes under Chlodomar. Julian's victory, due mainly to the superior discipline of the Roman infantry, resulted in the recovery of the Upper Rhine and the freeing of Gaul from barbarian invasions. Toward the end of the 5th century the town passed to the Franks, who gave it its present name. In 842 Charles the Bald and Louis the German took the Strasbourg Oath (*Serment de Strasbourg*), a text of which is the oldest written document in French. The town's connection with the German kingdom began in 923, through the homage paid by the Duke of Lorraine to the German king Henry I. The early history of Strasbourg consists mainly of struggles between the bishop and the citizens. This conflict was finally decided in favour of the citizens by the Battle of Oberhausbergen in 1262, and the position of a free imperial city which had been conferred upon Strasbourg by the German king, Philip of Swabia, was not again disputed. In 1332 there was an internal revolution, which resulted in admitting the guilds to a share in the government of the city.

In 1381 the city joined the *Städtebund*, or league of Swabian towns, and a century later it helped the Swiss confederates at Grandson and Nancy. The reformed doctrines were readily accepted in Strasbourg about 1523, and the city was skilfully piloted through the ensuing period of religious dissensions by Jacob Sturm von Sturmeck, who secured for it very favourable terms at the end of the War of the Schmalkaldic League. In the Thirty Years' War the town observed a prudent neutrality. In 1681, during a time of peace, it was suddenly seized by Louis XIV, and this unjustifiable action received formal recognition at the Peace of

Rijswijk in 1697. At the French Revolution the city was deprived of its privileges as a free town. In the Franco-German War of 1870–71 Strasbourg, with its garrison of 17,000 men, surrendered to the Germans on Sept. 28, 1870. The city and the cathedral suffered considerably from the bombardment. Strasbourg remained German until 1918 when it once again became part of France. At the outbreak of World War II the city was evacuated and in 1944 it suffered heavily under Allied bombing. On Nov. 23, 1944, it was liberated by General Leclerc.

Strasbourg is the seat of a bishop. The bishopric originally embraced a large territory on both banks of the Rhine, but it was diminished by the creation of the bishoprics of Speyer (Spire) and Basel. The episcopal lands were annexed by France in 1789 and the subsequent Roman Catholic bishops of Strasbourg discharged spiritual duties only.

Rouget de Lisle composed "La Marseillaise" there in 1792.

See also references under "Strasbourg" in the Index.

**STRASBURGER, EDUARD** (1844–1912), German botanist, one of the first to realize the importance of the nucleus and chromosomes in heredity, was born in Warsaw, then in Russian Poland, on Feb. 1, 1844. He studied in Germany at Bonn and at Jena. He returned briefly to the university at Warsaw in 1868; he was professor of botany at Jena from 1869 to 1880 and thereafter at Bonn till his death.

Strasburger contributed to the advance of many branches of botany. His first work was concerned with the embryology of gymnosperms, then with the more minute details of the life history of angiosperms. Later he turned increasingly to the study of the cell, and made many contributions to the solution of problems of cell and nuclear division in plants. He also studied problems of water transport in plants, and in his last years the inheritance of sex differences in plants.

Strasburger was also the foremost botanical teacher of his day. He wrote a number of textbooks, among which the "Bonner Lehrbuch," *Lehrbuch der Botanik*, first published in 1894 in collaboration with others, established itself as the standard textbook for botanical students the world over and was widely translated. He died at Bonn on May 18, 1912.

**STRATEGUS** (Greek STRATEGOS), a word meaning strictly a general, but frequently in ancient Greece a state officer with much wider functions.

In Athens the board of ten strategi was originally a product of the reorganization of the tribal system under Cleisthenes (q.v.) each of the ten tribal units being represented in the army by a *taxis* (regiment) led by a strategus; but there is evidence (Aristotle, *Constitution of Athens*, xxii) against the view that Cleisthenes himself created the board. In any case, in 490 B.C., at Marathon, the head of the army was still the polemarch (see ARCHON), Herodotus' story of successive days of command being based on a misconception of the powers of strategi. After 481, however, when the archons came to be chosen by lot, command of the *taxis* passed to taxiarchs subordinate to the strategi. In the 5th century, it was usual to appoint a number of strategi for a particular field of operations: while the chief command might be assigned to one of them, they often held coordinate powers (e.g., in the Sicilian expedition) or exercised the chief command in turn (e.g., at Arginusae). In crises, however, the whole board could be subordinated to one member (e.g., Pericles at the outbreak of the Peloponnesian War, or Alcibiades in 407). At first each tribe elected a strategus from among its members; but in the second half of the 5th century there are examples of two strategi being elected from a single tribe (e.g., Pericles and Glaucon in 433–4; Alcibiades and Adeimantus in 407–406); and in the later part of the 4th century the strategi were elected from the whole citizen body without regard to tribal divisions. The tribes, however, continued to elect the taxiarchs.

The political powers of the strategi were considerably increased in the 5th century, particularly in foreign affairs. Though apparently not members of the boule (council), they could attend its meetings, bring motions before it, and ask it for emergency meetings of the ecclesia (assembly), in which their business regularly took precedence of everything else. In concluding treaties, they

acted on the voted resolutions of the ecclesia. The appointment of strategi for specified departments dates from the 4th century.

Two aspects of the office made it important: (1) it was elective, as opposed to the magistracies filled by lot; and (2) strategi were reeligible indefinitely. A man who commanded popular confidence (e.g., Pericles) might thus not only obtain such commissions as could not be left to chance nominees but also be returned to power in subsequent years to profit from his experience. The board of strategi had no collective responsibility.

Military power prevailed over civil authority in the Greek world after Alexander the Great, and strategi became the supreme magistrates in most leagues and federations. Both in the Achaean and in the Aetolian League the strategus (helped by a commander of the cavalry or *hipparchus*) was the head of the state, being appointed for a year by the appropriate federal assembly: he was at once commander of the army, president of the federal assemblies, and foreign minister. The same man could not however be reelected in consecutive years; and in the Aetolian League the strategus was not allowed to make proposals about war or peace.

Alexander the Great appointed Antipater as strategus of Europe when he went to war against Persia. Polyperchon and Cassander filled the same position after Alexander's death; and Antigonus was sometime strategus of Asia. The governors appointed by the Macedonian kings over regions or cities of Greece were normally called strategi. In the Seleucid kingdom the provinces were governed at least in part by strategi, but details are controversial. There were provincial governors called strategi in other Hellenistic monarchies, and strategi appointed by the king are found in Pergamum. In Egypt the strategi became the civil governors of the nomes during the 3rd century B.C. (they almost completely lost their original military character); a special strategus governed the Thebaid; and there were strategi in the Ptolemaic territories outside Egypt. Under Roman rule strategi remained the heads of the Egyptian nomes until the 4th century A.D. There were officers with powers equivalent to those of strategi (and called strategi by Greek authors) in the Carthaginian state.

**STRATEGY**, narrowly defined, means "the art of the general" (from the Greek *strategus*). In a strictly military sense, the term first gained currency at the end of the 18th century, when warfare was still relatively simple and limited. In its military aspect, the term had to do with stratagems by which a general sought to deceive an enemy, with plans he made for a campaign, and with the way he moved and disposed his forces in war. Often defined as the art of projecting and directing campaigns, military strategy came to preempt almost the whole field of generalship, short of the battlefield itself. It also came to include the planning of naval warfare. To tactics (*q.v.*), military jargon reserved the art of executing plans and handling forces in battle.

The term strategy has expanded far beyond its original military meaning. As society and warfare have steadily grown more complex, particularly in Western civilization, military factors have become more and more inseparable from the nonmilitary in the conduct of war and in programs designed to secure peace. Nations have found it necessary to adjust and correlate political, economic, technological, and psychological factors, along with military elements, in the management of their national policy. The demarcation between strategy as a purely military phenomenon and national strategy of the broader variety became blurred in the 19th century, particularly in wartime. The distinction became even less clear in the 20th century when nations became more interdependent and the line between war and peace less clearly definable. As a result, the appearance of the term "grand strategy" (or "higher strategy"), meaning the art of employing all the resources of a nation or coalition of nations to achieve the objects of war

(and peace), steadily became more popular in the literature of warfare and statecraft of the 20th century.

This broadened scope of strategy has tended to blur distinctions customarily drawn by earlier writers between strategy and statesmanship, and between garden varieties and higher or "grand" forms of strategy. Though there is still no agreed definition of the precise meaning of the term strategy, few students of the subject any longer accept the earlier narrow definition. Also, few contest that strategy, whether in its narrow or broad sense, will, by the very nature of its shifting bases, continue to be a changing art.

  5. Between World Wars I and II
  6. World War II
  7. Cold War in the Nuclear Age

## I. FUNDAMENTALS OF STRATEGY

**1. The Search for Principles.**—The starting point of all strategic planning and action is national policy. Once the national aims are set forth by the leaders of the state, the commander sets about drawing up his plans. He must take many matters into account; for example, factors of space and time, the state of his own forces, the enemy's capabilities and intentions, and reactions at home and abroad to his projected moves. The strategist deals in many uncertainties and imponderables. Indeed, the art of the strategist is the art of the "calculated risk."

The growing complexity of modern warfare has led some students to take a fresh look at the principles that have traditionally guided military strategists in war. It has long been a favourite occupation of military theorists to seek to distill from the great mass of military experience simple but all-pervasive truths—lists of principles—to guide commanders. Usually they have derived such principles from a study of campaigns of the great captains of history; occasionally outstanding practitioners have set them down on the basis of personal experience. As far back as 500 B.C. Sun Tzu, a Chinese general, set forth 13 principles. The axioms range from Gen. N. B. Forrest's simple admonition about getting there first with the most men to Napoleon's 115 maxims. The stress varies from list to list. It ranges from the emphasis of the followers and interpreters of Karl von Clausewitz on the belief that the battle is all, and defeat of the enemy's armed forces the correct objective and path to victory, to that of exponents of "the strategy of indirect approach," of victory by indirect methods, such as B. H. Liddell Hart, eloquent advocate of the principle of "obliquity" in the 20th century.

Though there is no complete agreement on the number of principles, most lists include the following: the objective, the offensive, cooperation (unity of command), mass (concentration), economy of force, maneuver, surprise, security, and simplicity. The British have added one called "administration"; the Russians another, translated as "annihilation." Despite debate over their precise number and meaning, the principles of war are widely taught, and most military students accept them as basic concepts.

The individual authors of the lists have almost uniformly claimed the principles to be immutable. They have argued that success in military strategy in the past has been the result of adhering to them; that the advantages of the offensive, the concentration of force, the effort to achieve surprise, the proper movement of forces and their security from attack, sabotage, or subversion are in the province of modern as well as ancient warfare. Some authorities have even argued that since war is not the concern of soldiers only, the "principles" deserve a wider application throughout government—in grand as well as military strategy.

Other authorities have argued that the claim of immutability cannot be accepted literally; that there is little agreement as to

what the principles are and mean; that they overlap; that they are fluid and require constant reexamination; that they are not comparable with scientific laws since no two military situations are ever completely alike; that the so-called principles are not really principles at all, but merely methods and common-sense procedures adopted by great commanders of the past; and that changes in the conditions of war alter their relative importance.

The debate over principles was renewed with the coming of the atomic era. Some theorists argued that the new weapons had destroyed whatever value the principles once had; others contended that the principles were as valid as ever, even more so. To some extent this was a debate over semantics. Defenders pointed out that each age must make its own applications of the "fundamental truths" of strategy. Opponents argued that there can be no set rules for the art; the so-called principles must by no means be interpreted as pat formulas for victory to be followed blindly and rigidly; the only sound guide in war and strategy is flexibility.

**2. Relation Between Strategy and Tactics.**—In the theory of warfare, strategy and tactics have generally been put into separate categories. The two fields have traditionally been defined in terms of different dimensions: strategy dealing with wide spaces, long periods of time, and large movements of forces; tactics with the opposite. Strategy is usually understood to be the prelude to the battlefield, and tactics the action on the battlefield itself. As a result, much of the literature and theory of strategy has in the past been preoccupied with the proper approach to the battlefield, the leading of troops up to the time of contact with the enemy. This situation explains the attention to strategic maneuver—aimed at putting one's army into the most favourable position to engage the enemy and compelling the enemy to engage at a disadvantage and depriving him of freedom of movement. Indeed, early writers on strategy dealt heavily in the so-called "geometrical strategy"—the angles formed by lines of movement and supply of opposing armies. Sir Edward Hamley in his *Operations of War* has well described all the various permutations and combinations of strategic maneuver.

Despite distinctions in theory, strategy and tactics cannot always be separated in practice. In fact, the language of strategic maneuver (for example, "envelopment," "penetration," "encirclement") is also largely the language of tactics (see **TACTICS**). Movement begets action, and action results in new movement. The one merges into the other. Strategy gives tactics its mission and wherewithal and seeks to reap the results. But tactics has also become an important conditioning factor of strategy, and as it changes, so does strategy. Battles and fronts are no longer necessarily restricted in space and time, and the distinction between battles and campaigns is no longer so clear-cut, as the experience of World Wars I and II with tridimensional warfare demonstrated. Indeed, in World War II, theatre commanders were as much concerned with the actual fighting of armed forces in battle as they were with larger strategic decisions—with relations to allies, economic problems and political questions on the ground. While in theory strategy continues to occupy a middle ground between national policy and tactics, in practice the line dividing it from the other two fields has become increasingly difficult to draw.

**3. Strategic Leadership and War Planning.**—Count von Schlieffen, the famous German military leader, once said, "A man is born, and not made, a strategist." But it is obvious that even a born strategist—if there be such a natural genius—has much to learn. In the old days strategic leadership was a relatively simple affair. J. F. C. Fuller, the British student of warfare, pointed out in *The Foundations of the Science of War* (1926), that until relatively recent times the death, capture or wounding of either of two opposing generals normally decided a conflict, "for the general was the plan." He could personally devise the plans and direct his troops. By mid-20th century this was rarely possible. As warfare has become complicated, strategic leadership has become more difficult. The art has taken on many more facets and systematic training is required to master them. The strategist has retired from the scene of battle, and large, specialized staffs have grown up to help him. While the responsibility for strategy remains

the general's, many of his functions have been delegated to his planning staff. In modern states corporate leadership has become the rule in the management of military strategy, as in the direction of large business enterprises.

The example of an Alexander completing his advance planning and leaping into battle at the head of his troops, as at Arbela, would in modern warfare be considered most unusual. Napoleon was wont to make his plans and then retire with his retinue of trusted advisers to survey the battlefield on horseback from the top of a hill. Generals in World War I were often pictured in their offices in large headquarters—usually in a chateau behind the lines, studying a map on the desk and dispatching orders via the telephone and motorcar at hand. In World War II the headquarters staffs of commanders in the theatres of war grew even larger and more elaborate. Tridimensional warfare had enlarged the field of operations far beyond individual battlefields, and usually a high commander reached his decisions in a headquarters far removed from the field of battle and months before the battle itself took place. Far from striking the classic pose of the officer on a well-schooled charger, some of the greatest generals issued their orders from desks and fought their most important battles at conference tables. As strategic planning became a highly organized affair, planning committees and conferences in the capital cities of the warring powers made the blueprints for victory in the global, coalition struggle. In their capital command posts military leaders kept in touch with the manifold phases of the national government's war effort and dealt with the worldwide problems transcending those of the individual theatres of war. With the aid of new devices for rapid communication these leaders and their staffs sought to set the patterns of strategy and keep abreast of the movement of armies as the Caesars and Napoleons had done in earlier eras.

As war became more total, war planning became an increasingly significant peacetime function of governments. The manufacture of strategic plans has become a highly specialized industry in modern military establishments. At the same time, more and more governmental agencies have been drawn into the business of planning for national security. The plans they produce may vary from a simple design to shift a small task force to a danger spot to an elaborate plan for the conduct of war in its entirety. To be realistic, strategic plans and estimates must constantly be reexamined and brought into harmony.

Against this general background in the nature of the art, it is now possible to sketch the important contributions made in key periods to modern strategic theory and practice. It is important to remember that the art of strategy has changed from age to age, just as has war itself, and that each is the product of its own society and time.

## II. DEVELOPMENT OF STRATEGY

Though the serious and systematic study of modern strategy may be dated from the 18th century, various authorities have identified strategic precedents going back to earliest times. Students of warfare of primitive ages have associated with primitive tribes and clans a stratagem of surprise from darkness or by ambush, and they have identified a strategy of hunt and pounce, like that of a lion or tiger. The Bible points to the care with which Moses prepared his operations—an early form of advance planning. The ancient world developed a strategy of mass attack by phalanx, legion or cavalry. Alexander, Hannibal, and Caesar, when combined in their own persons political and military direction of the state, planned their famous campaigns far ahead. They have been singled out as forerunners of the modern art of grand strategy. Writers in modern times have used the campaigns of these great captains to illustrate practically every known "principle of war." But important as their attention to strategic considerations in war and especially to strategic approaches to the battlefield may have been, the foundations of the ancient art of warfare were tactics and battles. To a considerable extent battles—often short and furious—also held the centre of the military stage in the Middle Ages. Strategy was notably absent in the excursions of the Huns, the Muslims, and the crusaders. Far more important from

strategic viewpoint were the campaigns of Genghis Khan and his general, Sabutai, in the 13th century. Their advance planning and bold strategic maneuvers in broad sweeps from Mongolia across Asia and Europe showed an appreciation of strategic problems most unusual for their age.

In the transition to modern times two other figures who touched on the field of strategy are often mentioned—Niccolò Machiavelli in the realm of military thought and Gustavus II Adolphus in the field of generalship. Machiavelli's *Art of War* (1520) emphasized the larger aspects of war, particularly the close relationship between the civil and military spheres. A century later, Gustavus, ruler-general of Sweden, intervened in the Thirty Years' War, and, maneuvering skilfully, drove the imperial armies out of northern Germany.

**1. 18th-Century Warfare; Frederick the Great.**—After the death of Gustavus, warfare again settled down to a slower pace and a more stable mold. The 17th and 18th centuries saw the growth of professional armies loyal to the king. But the great cost of building and maintaining such armies led to a concern for their safety, a hesitation to risk them in bloody encounters and a preoccupation with defense and fortifications. Strategy was essentially of limited aim and was greatly concerned with the art of siegecraft, for which elaborate rules were prescribed. In Prussia of the mid-18th century, however, circumstances compelled Frederick the Great to try a new and aggressive approach and to break through the accepted military pattern of the day.

Confronted at the outset of the Seven Years' War (1756–1763) by a coalition of Austria, France, Russia, Sweden, and Saxony, Frederick found himself virtually surrounded. His task was to devise a strategy to defend his territory and not to dissipate his outnumbered troops. The strategy he evolved did not follow set rules or recipes. Indeed, never was the definition of strategy as a "system of makeshifts," offered in a later age by Count von Moltke, better demonstrated. In his planning Frederick capitalized on two valuable assets—his army, a superior and highly disciplined instrument of war, and a central position. He sought always to keep the initiative, to attack first one enemy and then another, to assemble at decisive points a force superior to that of his foe and to avoid long, drawn-out wars. Using his central position to concentrate against individual armies of the enemy before they could be reinforced by others, he developed the classical "strategy of interior lines." But even Frederick, the statesman-warrior, could not entirely escape the conditions imposed by the warfare of his times. Indeed, the statesman imposed caution on the warrior. He could not expose his costly armies to the risk of destruction and bloody decision by battle. His battles were not those of annihilation. In the end his wars were decided by reasons of state, and those wars left his nation exhausted.

The age that immediately followed Frederick chose to imitate his caution rather than his aim. Military theory was characterized by ideas of victory without battle, maneuvering for position, a system of lines and angles of operation. Geometric concepts and cunning tricks and artifices replaced the aim to destroy enemies. Great emphasis was put on terrain and the occupation of key geographic points. The 18th century, it must be remembered, was the era of enlightenment, and warfare conformed to the spirit of the age. Strategy, like all warfare, became "mathematical" and "scientific." Theorists optimistically maintained that a general who knew mathematics and topography could direct campaigns with geometrical precision and win wars without even fighting. But the new mode of warfare ushered in by the French Revolution and the Napoleonic era was soon to challenge these optimistic assumptions.

**2. Napoleonic Warfare; Clausewitz and Jomini.**—The French revolutionary and the Napoleonic periods witnessed great changes in the methods of war—the revolution in society accompanying and reinforcing the one in warfare. When Napoleon, the first great military strategist of the modern Western world, burst upon the European scene, the groundwork for a new age in warfare had already been laid. The French Revolution gave birth (1793) to the "nation in arms" and all Frenchmen became liable for military service. The patriotic citizen-soldier suc-

ceeded the mercenary professional. Skirmish tactics, or the loose formation, replaced the straight line; divisional organization came into use, along with lightweight artillery of great range and firing power. When Napoleon came to reap the benefits of these changes, he completely transformed strategy as well as tactics. He applied the same basic principle to the one as to the other—never to divide his forces, but to concentrate all his might against the enemy forces at the critical point. His emphasis was on careful preparation, on uniting his forces before the action, on overpowering weight of striking power, on shock attack, on great daring, and on bloody decision by battle. His methods were simple, direct, overpowering—even brutal; his aim was nothing short of the destruction of the enemy forces. Against such power, neat geometric calculations stood little chance and ordinary stratagems were helpless. Again and again he showed his military genius for bringing a mass to bear against the flanks of his enemy, for selection of battlegrounds advantageous to his forces, and for deploying his forces for battle. He gave supreme expression to the idea of victory by battle.

Though as a military leader, operational strategist and tactician of the battlefield he is regarded by many as unparalleled, in the larger field of national or grand strategy he showed shortcomings. Embodying in his own person the leadership of the state and its military affairs, he recognized the value of incorporating political and economic measures, along with military moves, to increase the chances of victory in war. But he could not successfully grasp and cope with the challenge finally put to him by Great Britain and its European allies. British strategy sought to meet the Napoleonic threat to Europe by using naval power to blockade the continent and by conducting a war of exhaustion on land through peripheral warfare, such as Wellington's famous campaign on the Iberian Peninsula. Napoleon's reply to the British naval blockade was the continental system prohibiting British goods from entering. But this helped bring his downfall, since he was needed everywhere—to hold the coast, fight in Spain, Holland, against Austria and Russia. His veteran French forces were dissipated and he had to rely on impressed nationalities of Europe. Eventually the coalition of his enemies was to use the methods and means of warfare that the French Revolution had introduced and Napoleon had perfected to reinvigorate their own forces and overwhelm him.

Despite his mistakes, Napoleon's preeminent place in the history of strategy is secure. His tactics and strategy influenced military leaders for a century. His maxims were widely studied and were said to have been carried in the saddlebag of the famous U.S. general, "Stonewall" Jackson. Students of strategy have long pointed to Napoleon's battles and campaigns for classical illustrations of "principles" of war—of surprise, mobility, concentration of force, and economy of force. Possibly more than that of any other general, his competent practice oriented modern military theory toward the search for underlying principles. Indeed, the art of strategy as evolved by theorists since 1800 may be traced largely to his operations.

For this development two great interpreters of Napoleonic strategy, Antoine Jomini and Clausewitz (*qq.v.*), were especially responsible. Clausewitz, a Prussian, the first great student of strategy and the father of modern strategical study, lived in the early 19th century. Trained in systematic study of philosophy in the school of Immanuel Kant, it was but natural for him to range widely over the whole field of military knowledge and to reduce Napoleonic warfare to a unified, philosophical conception. His famous work, *On War*, written as an outgrowth of his studies of Napoleon's campaigns, remains the best general study of the art of war. He died with his work unfinished, but his writings published after his death became the standard textbooks on war in Prussia and elsewhere. Their influence was felt profoundly in the Franco-Prussian War of 1870, and leading generals of World Wars I and II were brought up on them and on the works of his followers.

The contributions of Clausewitz to strategic thought are many and diverse. To some his work is the Bible of strategy, and, like that great book, susceptible to many conflicting interpretations. His work set forth fully and clearly for the first time the relation-

ship between political and military leadership. He dwelt on decision by battle as the first rule of war; on seeking the destruction of the enemy's forces; and on achieving superiority at the decisive spot. Rejecting the optimism and rationalism of the 18th century, he held that war was not a scientific game but an act of violence. Mathematical and topographical factors, he held, were important in tactics, but less so in strategy. "We . . . do not hesitate," he asserted, "to regard as an established truth that in strategy more depends on the number and the magnitude of the victorious combats than on the form of the great lines by which they are connected" (*On War*, vol. 1, bk. 3, ch. xv, p. 223, Routledge & Kegan Paul, Ltd., London, 1940). The key to victory was battle, however bloody. Strategy he defined as the employment of battles to gain the end of war.

Clausewitz devoted much of his work to showing that war is both a social development and a political act. He went further and said that, "War is not merely a political act, but also a real political instrument, a continuation of policy carried out by other means" (Maj. Gen. Sir F. Maurice, *British Strategy*, p. 44, Constable & Co., Ltd., London, 1929). War was therefore not an independent phenomenon unto itself to be handed over to soldiers and sailors. Again and again he asserted that military and political strategy must go hand in hand. "War," he declared, "admittedly has its own grammar, but not its own logic" (*On War*).

Clausewitz' emphasis on the aim of strategy as the destruction of the enemy's forces on the battlefield has had a great influence on subsequent military thinking. His disciples, however, have generally overlooked the fact that he also recognized another strategical form—a strategy of limited aim for limited warfare, of wearing down an opponent. When Clausewitz wrote, warfare was conducted in two dimensions, and it was rarely possible for one nation to impose its will without first destroying the opposing army. But Clausewitz recognized clearly what many of his followers in subsequent generations forgot, that the destruction was only a means to enforce policy and not an end in itself.

In the history of military thought, the French general Jomini, one of Napoleon's staff officers and a contemporary of Clausewitz, presents a striking contrast to the Prussian philosopher of war. Lacking the philosophical bent of Clausewitz, Jomini concentrated his thinking on what he regarded as practical issues in war rather than on war as a whole. He became the chief expounder of Napoleonic methods, and out of his studies evolved a theory of strategy. Although he opposed "systems of war" purporting to provide for all contingencies, he nevertheless believed that in the field of strategy certain rules and general principles—eternally true—could and should be formulated "as a compass for the commander-in-chief of an army." To establish these principles, he believed, was the major problem of military science.

The heart of Jomini's theory lay in the theatre of war and the campaign. But he thought primarily of occupying all or part of the enemy's territory rather than of annihilating his army. This occupation was to be achieved by progressive domination of zones of territory. Jomini emphasized throughout his work the proper choice by the general of decisive maneuvering lines and their adaptation to geometrical configurations of zones of operation. Campaigns must be carefully planned in advance. The task of strategy is to make preliminary plans—to establish lines of operation and to bring military means into conformity with geographic realities of the chosen zone of operations. He laid down two basic principles: massing troops against fractions of the enemy by rapid movement, and striking in the most decisive direction.

Jomini's great contribution to military thought lay in his definition of the place of strategy in warfare. Probably more than any other work, his *Précis* fixed the major fields of modern military art. Subsequent wars were to cast doubt on much of his work, particularly on his conception of geographical campaigns and of the superiority of interior lines of operation. But, like Clausewitz in German strategic thinking, Jomini had an enduring influence on French military thought. His emphasis on planning for operations and on intelligence took root in military staffs and schools throughout Europe, and his work became the textbook for the conduct of the American Civil War. It has been said that the

Civil War was fought with Jomini in the pockets of all the leading generals.

**3. American Civil War to World War I.**—Often called the first of the really modern wars, the American Civil War marked a transition to a new era in strategy. It gathered up new phenomena that had begun to influence warfare in the middle of the 19th century and whose fuller consequences were to be felt in the half century that followed. It was a period marked by refinement of the old in strategic theory and practice and by the addition of new strands—by such famous figures as Lee, Grant, and Sherman on the battlefield; Moltke, Schlieffen, Delbrück, and Mahan in the literature of strategy.

The Civil War is significant in the history of strategy in a number of ways. The basis of strategy—particularly factors of time and space—began to change. The use of steam power for land and water military transportation received its first major test. Railroads gave strategy a new speed of movement but tended to make strategy stick to straight lines and fixed routes. The Civil War also tested ironclad ships and heavy naval ordnance. The relation among the combat arms was completely upset by the introduction of the long-range infantry rifle. Artillery could no longer unlimber at case-shot ranges. The accuracy of long-range weapons in the hands of defending infantry shattered the effectiveness of the rapidly concentrated attack in which Napoleonic strategy had culminated. But, as so often has been noted in the history of warfare, armaments and weapons are more readily changed than ideas, and Napoleon's principles continued to be maintained, sometimes with disastrous consequences on the battlefield.

Aside from the effect of new inventions, the Civil War revealed the growing importance of the economy and manpower in war. Industry was called on more and more, and conscription was adopted to provide manpower. The war also revealed the impact of systematic West Point training received by the leading generals on both sides. In fact, it may be said that if the higher officers carried Jomini in their pockets, they carried in their minds the teachings of Dennis Hart Mahan, father of Alfred Thayer Mahan and one of the few outstanding U.S. students of strategy. Finally, the Civil War was long studied for classic examples of maneuver, and of offensive and defensive strategy, and for lessons in the relation among policy, strategy and means of war. Essentially the Civil War demonstrated local or theatre strategy and tactics. Though elements of grand strategy were at hand—political, economic, military and psychological—the art was still not well understood or consistently applied. Despite conscription and the partial mobilization of industry and the railroads, there was no well-worked-out grand design correlating the widely scattered forces and the war industries that supported them.

The strategies of the North and South were rooted in different political objectives. The objective of the North was to prevent the Confederate states from seceding from the Union; that of the South was to attain independence. Since the South was greatly inferior to the North in population and resources it could not hope to conquer the North. The dual purposes of its strategy were: (1) to convince the North that forcing the South to remain in the Union was not worth the cost; and (2) to bring about foreign intervention in favour of the South. Gen. Robert E. Lee, the great Southern leader, believed the best way to realize these objectives was to carry the war into the North and to defeat the Northern armies in their own territory. For a time, therefore, his strategy was essentially offensive. But after his defeat at Gettysburg he no longer had the wherewithal to continue the offensive, and at the same time it became obvious that foreign intervention would not be forthcoming. From that time to the end of the war his strategy was defensive, with the object of wearing down the patience, if not the power, of the North.

To achieve its political object, the North, on the other hand, developed another strategy. The Federal design had three main goals: (1) to isolate the Confederacy; (2) to cut it in two; and (3) to strike at Richmond, its capital. The blockade, though not completely effective, brought virtual commercial isolation to the South. Partition was gained by capturing Vicksburg, in July 1863.

and by severing the east-west railroad connections. The capture of Vicksburg cut the South off from its sources of supplies beyond the Mississippi. Only gradually did the North change its design from that of attacking Richmond to that of striking at the main army of the Confederacy and the remaining sources of supply. Grant's elevation to the supreme command of the armies enabled him to put this concept into effect. The famous march of Gen. William T. Sherman through Georgia to the sea in 1864 was an outstanding example of strategic maneuver and surprise. Leaving his supply line, Sherman feinted against one city and attacked another, finally cutting off Lee's army in Virginia from its war resources in the South. The cooperation of the Federal eastern and western armies in a grand converging movement resulted in the evacuation of Richmond and, finally, in the surrender of Lee's army to Grant at Appomattox in April 1865.

The period from the close of the Civil War to the outbreak of World War I saw the further growth of trends already apparent. Space and time factors began to appear in a new light. A nation with a well-developed railway net gained significant advantages in war. The speed of mobilizing and concentrating armies became a basic element in strategic calculations and the timetable based on it the heart of staff plans drawn up in anticipation of war. Increased fire power in the machine gun, universal liability of able-bodied males for military service, rapid mobilization of reserve military units and increased potential of fortifications influenced military planning.

In strategic thinking the half century before World War I showed a remarkable diversity. To the Prussian-German school—Moltke and Schlieffen—the new trends in warfare seemed to reinforce Clausewitz' teachings about battles and the aim of defeating the enemy's armies. Battles, Moltke agreed, were the primary means of breaking the will of the enemy. But Moltke did not believe a strategist could follow a rigid set of rules. To him strategy was a system of "*ad hoc* expedients." It was "the art of action under the pressure of the most difficult conditions." No plan of operations, he believed, could look with any assurance beyond the first encounter with the main enemy forces. The offensive, according to Moltke, is "the straight way to the goal," whereas the defensive is "the long way around." He became famous for his skilful conduct of operations on the outer line leading to encirclement, and Königgrätz and Sedan (see *SEDAN: Battle of Sedan, 1870*) remain as supreme models of such strategy. In addition to exploiting the altered conditions of space and time created by the railroads and improved highways, he capitalized on the possibilities offered by the telegraph for handling armies of great size. Recognizing that the field of operations had become too vast to be surveyed by the eye of the commander, he introduced a new system of delegating power to subordinate commanders. Broad directives took the place of detailed orders. Moltke always fought with superior forces, and his wars, culminating in that against France in 1870-71, are regarded by some authorities as classical models of conception and execution in military strategy.

Field Marshal von Schlieffen, chief of the Prussian general staff before World War I and ablest of Moltke's successors, carried the strong line of strategic reasoning running from Napoleon through Clausewitz and Moltke to its logical conclusion in his conception of a "strategy of annihilation." Like Moltke, he stressed the military side of strategy, the concentration on decisive victory by battle. But, unlike Moltke, he could not count on superior forces and had to prepare for war on two fronts. The basis for German strategy before World War I as developed by him became that of the inner line—a conception that was embodied in the famous Schlieffen plan. The plan was extremely simple. The bulk of the German forces were to attack the nearest opponent, the one in the west, and to defeat him in a great battle; meanwhile, in the east the Germans would stand on the defensive. Schlieffen proposed to gain the decision in the great battle by means of an enveloping attack—if possible, by a double envelopment. Once the enemy in the west was defeated, the Germans would attack the foe in the east. This was the essence of the plan with which the Germans entered World War I.

Schlieffen's theories were to have wide influence, largely through

his book, *Cannae*. Analyzing Hannibal's great victory over the Romans, he had developed his theory of the battle of annihilation by means of encirclement and double envelopment. The decisive German campaign at Tannenberg in Aug. 1914 was fought in this mold and Schlieffen's theories were studied exhaustively in the higher army schools of the United States and Europe after World War I. As Gen. Walter Bedell Smith, chief of staff to Gen. Dwight D. Eisenhower, supreme commander of the Allied Expeditionary Forces in World War II, pointed out, General Eisenhower and many of his staff officers, products of these schools, "were imbued with the idea of this type of wide, bold maneuver for decisive results."

Moltke and Schlieffen thought of war as military action—the speediest decisive defeat of the main opponent. But the closing years of the 19th and early years of the 20th centuries witnessed the emergence of new approaches and different emphases in strategy. Two thinkers looking to past history for light on the problems of their times made signal contributions to strategic theory—one, Alfred Thayer Mahan (*q.v.*), an American, in the field of naval strategy; the other, Hans Delbrück, a German, in the area of military strategy. Each recognized an intimate relationship between war and politics in every age; that political and military (or naval) strategy must be in harmony. Each showed an awareness of the growing importance of the economic bases of strategy, of state policy, geographic position, and available means as determinants of the mode of strategy; of accommodating strategic action to suit the particular times and needs.

Carrying forward a line of thinking already suggested by Clausewitz, Delbrück presented his theory of the "strategy of exhaustion"—of wearing down an opponent by a variety of means. Clausewitz had merely indicated the existence of two methods of conducting war—one aimed at annihilation of the enemy; the other, limited warfare. Delbrück expounded on the differences. The sole aim of the strategy of annihilation he identified as the decisive battle. The second type he called variously the "strategy of exhaustion" and "two-pole strategy." The commander could move between battle and maneuver; the political object of war could be obtained by other means than battle—by occupying territory, blockade, destroying crops or commerce. In Delbrück's view, Alexander, Caesar and Napoleon had been strategists of annihilation; Pericles, Gustavus Adolphus and Frederick the Great, equally great generals, exponents of the strategy of exhaustion. Holding that the strategy of exhaustion was just as valid as the strategy of annihilation—each depending on the political aims and means at hand—Delbrück's theories ran counter to the military thinking of his day and brought down a storm of criticism about his head. But he persisted in reminding his age, intent on victory by battle, of other important and forgotten aspects of Clausewitz' teachings.

While Delbrück was battling his military critics in Germany, a scholarly navy captain-teacher at the Naval War College in Newport, R.I., was quietly breaking ground in pursuing his brilliant researches in military and naval history and strategy. This pioneer was Alfred Thayer Mahan, indefatigable student of the strategy of Napoleon, Jomini and Nelson. His masterly works, *The Influence of Sea Power upon History, 1660-1783*, published in 1890, and *The Influence of Sea Power upon the French Revolution and Empire, 1793-1812*, published in 1892, marked a revolution in naval thought. While advances in technology were affecting naval architecture and weapons, and steam, armour plate, and rifled guns were coming into vogue, Mahan aimed to bring naval strategic thinking up-to-date. The books and articles that poured from his pen down to World War I about warfare of the second dimension—the sea—had a profound influence on the theory of warfare and on naval policy and strategy in the United States and abroad.

An advocate of a big navy, of overseas bases, of national greatness through sea power, he was the American apostle of "looking outward." Mahan emphasized the significance of commerce in war and of economic warfare through the application of sea power. His researches convinced him that the nation or group of nations that commanded the seas could best draw on the trade, wealth, and economic resources of the world and was the more likely to win

wars. Strongly influenced by Jomini's teachings, he looked for fundamental truths and formulated "principles" of naval strategy. Naval strategy and sea power, he recognized, were conditioned by a nation's insular or continental situation. To Mahan a central position gave the same great advantages on the sea or on land—interior lines. Concentration of force he viewed as a fundamental principle of land and sea warfare. The backbone of fleet strength, in his opinion, was the battle- or capital-ship. Under Mahan's tutelage, command of the sea approaches took the place of the twin theories of coastal defense and commerce raiding that hitherto held sway in American naval strategy. His concepts of naval strategy and faith in preponderant naval power and the use of the navy as an instrument of national power were accepted by the U.S. Navy and Pres. Theodore Roosevelt. His doctrines stimulated the trend toward overseas expansion and growth of the navies of the world between 1898 and 1914. The resultant acquisition of an overseas empire almost overnight in 1898 greatly changed the strategic position and problems of the United States. Its emergence as a world power, beginning in these years, was to have important bearings on the strategic balance of power among the nations of the world, an equilibrium that World War I altered profoundly. (See further SEA POWER.)

**4. World War I.**—World War I, the first of the great coalition wars of the 20th century, was an important landmark in the story of the evolution of modern strategy. Never was the phenomenon of cultural lag as applied to warfare more clearly demonstrated. Beginning in the accepted mold of strategic planning popular since 1870, it soon ran head on into counter trends that were altering the very bases of strategic action and that strategic thinking in the intervening years had not yet fully grasped. Despite the experiences in the Boer and Russo-Japanese wars with the machine gun as a defensive weapon of tremendous fire power, French and German military leaders at the outbreak of the war continued to put their faith in the offensive. In fact, they were convinced that new weapons and methods of control, the radio and telephone, actually improved the offensive capabilities of their mass armies. The universal underestimation of the effect of modern firearms on the defense had important repercussions on strategy both during and after the war.

The first moves in the war began in 1914 as French and German strategists had planned—the Germans in accord with the Schlieffen plan, the French with their Plan XVII. In seven days the Germans concentrated over 3,000,000 men on the eastern and western fronts from mobilization points. In approximately the same time the French assembled 1,200,000 men on the western front. Both sides made heavy use of railroad lines to speed assembly of great masses of troops. Both sides were determined to attack. Out of the movements of mass armies came the first battles on the frontiers. As Schlieffen had planned, the Germans catapulted into Belgium, but the enveloping wing was not so strong as Schlieffen, who had died the previous year, had wished. It was compressed into a smaller corridor by the political decision not to violate Dutch neutrality. The anticipated six-week campaign of annihilation against France envisaged by Schlieffen could not be executed. The French attack also soon hit a snag. Though the French Army's right wing reached the Rhine, its centre was endangered by a German pincer movement. Only a hasty retreat and a counter-offensive at the Marne saved Paris. The so-called pinwheel strategy—each side attacking and driving the enemy back—had stalled badly. (See further WORLD WAR I: Introduction.)

Meanwhile on the eastern front the German prewar strategy of holding until France had been quickly defeated was compromised by the desire of the Austrian ally to push against the Russians, partners of the French. The German victory at Tannenberg counterbalanced the Austrian defeat at Lemberg. The eastern front became stabilized.

By the close of 1914 the war had become a stalemate on both the eastern and western fronts. The conflict had resolved itself into trench warfare from Switzerland to the English Channel. Machine guns and artillery took over the battlefield. The conflict had settled down into a war of position, and strategic mobility was lost. World War I became a classic case of arrested strategy.

By the close of 1914 the first phase of the war was over. Pre-war plans had failed; the war of movement, of mass offensives had ceased. The big question thenceforth was how to dig the war out of the trenches. In answering that question important elements of grand strategy came into play. The heavy demands upon industry for munitions of war multiplied, and technology was called upon for new means—the tank and poison gas—of breaking the stalemate. Britain's naval blockade to starve Germany took on added significance. (See BLOCKADE.) The German counter-measures helped bring the United States into the war in 1917. But the United States, as usual in its military history, was not prepared for war. The buildup of its forces across the Atlantic was slow. The Germans, seeking in 1918 to forestall the full impact of U.S. might, put their resources into a great offensive which came close to succeeding. When the Americans, led by Gen. John J. Pershing, finally arrived in force, they played a valuable part in military strategy in reducing the salients within the Allied lines, such as that at St. Mihiel. Eventually the German allies defected, German armies reached a point of exhaustion and the homeland a stage of semistarvation. Germany asked for an armistice.

Though much has been written on World War I, the strategic lessons of that conflict for coalition warfare have not been fully comprehended. Never was the dependence of strategy on statecraft more clearly demonstrated. As political circumstances of the war changed, strategy changed. The Central Powers, led by Germany and Austria-Hungary, never had a common plan of campaign or effective unity of command. The Allied side achieved unity only under the pressure of necessity. Along with the military factors, economic and psychological considerations proved important in conducting the war and gaining the victory. Though the aim of annihilating the enemy was paramount with both sides—especially in the opening campaigns—the desire to exhaust him also influenced strategy. At the same time fresh confirmation was given to Moltke's description of strategy as a "system of make-shifts."

Military leaders in World War I had to master three basic factors in strategic calculations: masses of men, technological advances, and wide areas. The movement of huge masses became an art in itself, for armies had taken on unprecedented dimensions. Millions of men were in action. Railroads and motor transport became important not only for concentration but also for establishing new strategic points on the fronts themselves. The arena of war embraced whole continents. Battles lasted for days and weeks, and the fighting continued even after the great battles were over.

New weapons came into play. Aerial reconnaissance enabled a commander to gain some insight into the enemy's intentions and movements. New means of communication—telephone, radio, telegraphy, the automobile, and the airplane—promoted faster execution of orders and unified command over widely scattered forces. The overwhelming firepower of modern weapons checked the effectiveness of the attack, long considered the ideal path to victory. The tank, however, offered fresh possibilities in redressing the balance between the defensive and the offensive. Tactics became more than ever a prelude and conditioning factor of strategy, since without freedom of movement, strategy was only an academic exercise. Tactics came to mark the beginning rather than the conclusion of an operation.

But there were also larger strategic influences at work. If World War I was a war of masses, it was also a war of matériel. War was becoming increasingly total and cut deeper into the life of the nation. Some of the foremost leaders and students of World War I—notably Winston Churchill and Georges Clemenceau—recognized that military strategy had become but a part of a greater national strategy. Symptomatic of this thinking was Clemenceau's widely quoted statement that war was too important a business to be left to soldiers. More than ever strategy and politics would have to be correlated. The increasing totality of modern war would have to be matched by a broader national strategy. But the larger impact of the war in the international sphere—the effects of the defeat of Germany, the weakening of England and France, and the rise of the Soviet Union on the strategic balance of power in the world—could not yet be foreseen.

**5. Between World Wars I and II.**—The period between 1918 and 1939 saw strategy once more in process of flux. As an outgrowth of the experience of World War I, strategy came largely to mean defense. In France, particularly, a Maginot Line mentality began to take hold. The belief was strong that field fortifications aided by the machine gun would contain any attack. The huge losses of World War I would thereby be avoided.

But countertrends were soon to dispute this prevalent emphasis in strategic thinking. One strong challenge came from the new school of exponents of air power. In World War I the air arm had had its beginnings. The period between the end of World War I and the beginning of World War II saw it come into its own; air forces and air organization expanded greatly. Theorists began to develop the strategy of warfare of the third dimension. Foremost among these was the Italian Gen. Giulio Douhet. He first presented the doctrine that the air arm alone would decide wars of the future. In his view, land and sea forces would no longer be decisive. On the ground, armies could act henceforth only on the defensive, since attack, and with it the decision, could be gained only through the air. Air power could quickly conquer time and space. The air arm could circumvent every kind of ground resistance and nullify fortified positions and obstacles of terrain. It could strike at the enemy's sources of power before his armies could fire a shot. It could strike at his capital, industrial centres and communications. In short, it could so reduce his ability and willingness to resist that he would surrender. Douhet proposed to expand the air arm as much as possible, keep land and sea forces only as support for war in the air, and gain control of the air by defeating enemy air forces in battles or destroying them in their airfields. He made strategic bombing, and the industrial objective—strikes at the opponent's heart—the core of his doctrines.

Douhet's epoch-making ideas found many supporters in other countries, including the United States. This school of thought generally argued that huge armies would no longer be necessary. The opponent's will could be overcome even if his armed forces remained undefeated. Some of Douhet's adherents went further and demanded the abolition of land and sea forces altogether. In any event, the rise of air power accentuated the need of thinking of strategy as dealing with something more than the movements of armies on land, or of ships at sea. (See further AIR POWER.)

Meanwhile, army leaders began to advocate another solution to break the strategic stalemate of World War I. To overcome the superiority of the defensive, they put their faith in developing a modern cavalry of tanks and armoured, motor-driven vehicles. The best known among the great champions of mechanization and motorization that arose in Great Britain was Maj. Gen. J. F. C. Fuller (q.v.). These advocates saw in the armoured vehicle, combining firepower, extreme mobility and armoured protection, the best answer to overcoming defensive forces relying on machine guns. This system was particularly suited to needs of an insular country, protected by a strong air force and navy, and of a relatively small army intended primarily for expeditionary purposes in support of continental allies. But this solution on the ground found support in Germany, Russia, and the United States. In France, Charles de Gaulle bucked the strong tide of opinion and advocated tank warfare to restore a strategy of mobility and the offensive. (See also TANK.)

In the late 1930s the Germans combined air power and tanks into a new form of assault that also aimed to overthrow defensive superiority. Developing a highly mobile form of warfare for lightning strikes and mechanized attacks, they were to contribute the art of the blitzkrieg—the spearhead of a conquering, offensive strategy that Hitler unleashed in World War II.

In Germany, too, other influences supporting offensive strategy came to the fore. To overcome strategic stalemate of the World War I variety, Erich Ludendorff contributed his theory of total war. He envisaged total mobilization of a nation's manpower and resources for war. The nation at war would be led by a supreme military commander; strategy would dictate policy. The concept of total war moved geography and economics into prominent positions in Nazi thinking. Even before World War I the British geographer, Halford J. Mackinder, had posed the potential threat of

a heartland power, in control of Eurasia, to sea power—a counter to Mahan's theory of control of the seas. Led by Karl Haushofer, the German geopoliticians after the war took over the "heartlands" concept. Through their teachings the concept of control of Eurasia became imbedded in Nazi statecraft. Their doctrines gave support to the main strands in Hitler's offensive strategy—continental expansion, autarky (national economic self-sufficiency), and *Lebensraum* ("living space").

Before war burst upon Europe in 1939, it was apparent that important changes were also brewing in naval strategy. All major sea powers were producing high-speed battleships and the aircraft carrier was becoming a significant and integral member of the fleet. In the crucible of World War II the emerging elements in ground, air, naval, and nonmilitary strategy were to take clearer shape.

**6. World War II.**—Strategy came into its own in World War II. Global and coalition warfare on an unprecedented scale required global and coalition strategy to match it. The new trends in military, air, and naval strategy were put to the test. At the same time the worldwide conflict lifted strategy out of the purely military sphere into the field of grand strategy and international relations. The war cut more deeply than ever into every phase of life. It touched all nations, directly or indirectly, all continents and oceans, the air, the land, and the sea. Political, economic, technological, and psychological factors were drawn into the web of the strategy of all-out effort. The strategy for war grown increasingly total was conditioned by massive armed forces, revolutionary scientific and technological advances, tridimensional warfare, and miracles of industrial production and logistics.

World War II began with independent offensive moves of the Axis nations, Germany, Italy and Japan. Though these nations formed a war coalition, they never formulated a common blueprint of strategy or achieved the degree of cooperation that the Allied coalition did. Nevertheless, the Axis war effort marked an epoch-making development in strategy. The Axis concept of total war, particularly as developed in Nazi philosophy, revealed more clearly than before that the traditional view of strategy—the art of employing military forces—was too narrow. Diplomacy, propaganda, "fifth columns" and espionage, geography, economics, technology, and morale all entered into the Nazi concept of strategy. In Nazi strategy, the line between war and peace could no longer be clearly defined. The course of Hitler's campaigns, before and after the outbreak of actual war in 1939, showed that military operations and battles were only the last resort against an enemy, to be applied after all other modes of conquest had failed. Hitler early recognized that armed forces are only one of many means available to grand strategy. Indeed, his greatest victories were the bloodless ones before Munich. After war was joined in Sept. 1939, following the invasion of Poland, military strategy perforce came into greater play. Like Caesar and Napoleon, Hitler combined in his own person the two functions of strategy and policy. But his reputation as a military strategist was not to compare with his early triumphs in political warfare.

Hitler gave the art of offensive strategy a new twist. Like Napoleon, he failed to master all the elements of grand strategy. But in developing and correlating an assortment of modern means of breaking an enemy's will, he showed himself to be far ahead of his opponents.

Despite great German blitzkrieg victories on the continent, successes in the Middle East, and strategic bombardment of England, the winter of 1941 found Germany still without the victory it sought. Though it had tried to avoid a two-front war, by June 1941 it had become embroiled with the U.S.S.R. In December the Japanese struck at Pearl Harbor and the United States came in to aid England and the U.S.S.R. against the Axis powers. The worldwide strategic contest was then joined in earnest. The Axis nations had the advantage of interior lines; the Allies, other than Russia, had to fight on exterior lines, and their lines of support had to fan out from the factories of Britain and the United States all over the world. Inevitably the Allies turned to the strategic weapon of blockade against the Axis powers, and Germany and Japan turned to submarine warfare to cripple the Allied lifelines.

The story of Allied strategy in World War II is the search for

common denominators among three sovereign powers drawn together by a common bond of danger. That strategy was a product of many minds on both sides of the Atlantic, of diverse pressures and pulls, and of changing circumstances in the global war. It was the result of an evolutionary process and a series of compromises, and of a constant struggle to adjust ends and means. Above all, it was fashioned by powers with diverse national interests. If the national objectives sought by each of the participating powers were unchanging, the means and methods used by each to achieve them varied from time to time. In the process of planning and waging the war, moreover, the foundations of the alliance shifted and the relationships among the powers changed. These shifts are part and parcel of the strategy story.

That story falls into at least three phases. The first of these covers the period 1941-42. This phase saw the formation of the grand alliance and the emergence of divergent British and American concepts of strategic theory.

The grand alliance was a marriage of expediency, forged in war and cemented by the common bond of danger. But each member of the alliance expected different things from the partnership; each, because of its distinctive traditions, policies, interests, and position, looked at the war through different spectacles.

Great Britain, an island dependent upon sea lanes for its very existence and situated precariously on the edge of Hitler's European fortress, had for centuries put its faith in the balance of power. It was natural for it to seek to rally the smaller nations and oppose any strong power that threatened to upset the balance on the continent. It could be expected to intervene actively in the Mediterranean and the Middle East through which ran its lifeline to the empire in the East. But in any global war Great Britain's resources were bound to be stretched thin. Its economy, while highly industrialized, was small in comparison with that of the United States. Keenly conscious of its heavy losses in manpower during World War I, Britain would tend to avoid as long as possible large-scale ground battle on the continent. By necessity and choice, therefore, the leaders of Britain put their faith in the navy, the air force, and the mechanized and armoured forces. Experienced in war, diplomacy, and empire, Great Britain had a long history of alliances with European powers. Its admirals and generals were accustomed to working closely with the politicians and diplomats, and British strategy usually reflected political objectives.

Across the Atlantic lay the other major western power in the alliance, the United States—young, impatient, rich in resources, and highly industrialized. Traditionally opposed to becoming involved in European quarrels, it nevertheless had strong bonds with Europe, especially Britain. To most U.S. citizens war was an aberration; an unwelcome interruption to the normal course of events. Though its tradition in war had been first to declare, then to prepare, the country had between 1939 and 1941 gradually awakened to the dangers from without. It began to mobilize manpower and resources. Aid to Britain became official national policy in 1940, and lend-lease, a strategic weapon, was extended to Britain and other friendly powers in 1941. The strategic planners in Washington, laying aside their earlier academic exercises, began to think of global and coalition warfare. Without committing the administration, the military planners entered into staff conversations with their British opposites on possible ways of using U.S. forces in coalition strategy. For the first time in its history the United States entered a war well advanced in its military planning. The United States also had considerable interests in the Far East and a tradition of helping China. Throughout World War II the U.S. military staff and the president could not neglect the war in the East any more than the U.S. public could forget the attack on Pearl Harbor. One other factor that distinguished U.S. policy and strategy was the loose relationship between the president and the military. That relationship was in sharp contrast to the closely knit politico-military system of Great Britain.

The third major partner in the alliance against Germany was the Soviet Union, a land power with completely internal lines of communication. Though it possessed an enormous population and great resources, the Soviet Union's industrial facilities were still

not fully developed. The U.S.S.R. represented an enigmatic force, devoted to a political and economic ideology different from that of the western partners. Born in revolution and come to power in a civil and foreign war, its policies seemed to combine Russian national socialism, Marxism, and tsarist imperialism. Dedicated to the proposition that war was inevitable in capitalist society until the world revolution ushered in a new millennium, it had developed a strategy of revolution—based on the theories of Marx, Engels, and Lenin. In that theory, as in Nazi strategic theory the line of demarcation between war and peace was not clearly drawn. Until attacked by Germany, Soviet policy was dominated by the twin notions of security and expansion. The Nazi invasion reinforced the Soviet desire to strengthen its position in eastern Europe—an objective whose roots lay deep in Russian history. But for almost two years after the German attack the Soviet Union was engaged in a desperate fight for existence. Lacking air and naval traditions, it relied on geography, the loyalty of its people, and the huge Red Army to see it through. Political and territorial ambitions were subordinated to military necessity. Still fearful of capitalist encirclement, suspicious of friend and foe, the Soviet Union held an uneasy position in what Gen. John R. Deane, head of the wartime military mission in Moscow, later so fittingly called "the strange alliance."

From the beginning, the inner web of the grand alliance was the close relationship between the United States and Great Britain. The Soviet Union's part in developing and directing the combined strategy of the war was to be relatively small. Compared with the worldwide demands facing the United States and Great Britain, its strategic problem was simple. Unlike the western partners, the U.S.S.R. would be at war on only one front at a time; it did not enter the conflict with Japan until the closing days of World War II. The Soviet relationship with its western partners consisted of demanding material aid and increased pressure against the common enemy. But collaboration was to prove difficult even in these areas. Actually the strategic decisions of the western powers were normally transmitted in general terms to the Soviet Union. The Russians took formal part in strategic decisions only at the international conferences at Moscow (Oct. 1943), Teheran (Nov. 1943), Yalta (Feb. 1945), and Potsdam (July 1945), and even these were called at the initiative of the western powers. Throughout World War II, the Russians remained outside the combined staff system, developed for the coordination of the western effort in the global war.

The basic procedures for formulating Allied strategy emerged in 1941 and 1942. Shortly before Christmas 1941, Prime Minister Winston Churchill and his principal military advisers arrived in Washington for the first of their great wartime conferences with Pres. Franklin D. Roosevelt and his staff. Out of this meeting—the Arcadia Conference—came the establishment in Washington in Jan. 1942, of the Combined Chiefs of Staff (CCS), the agency for hammering out Allied strategy and for day-to-day conduct of the war. To supply U.S. opposites for the British in the combined organization, the United States Joint Chiefs of Staff (JCS) and joint staff planning system (army, air and navy) came into being. Since the three principal British military officers normally had to direct the operations of their services from London, they sent senior representatives to function for them in the Combined Chiefs of Staff. As finally constituted, the JCS was composed of the president's chief of staff and the senior officers of the Army, Navy and Army Air Forces.

The CCS was a unique organization in coalition machinery. Decisions were arrived at by common agreement; no votes were taken. The leaders concerted policies and plans, outlined strategies, discussed timing of operations, approved programs of allocations and measured requirements against resources. Their decisions were, of course, subject to the approval of the president and the prime minister.

The prime minister and the president, who were over and above the CCS system, were responsible for all decisions. Each wore two hats—one political, the other military. As political leaders they sometimes had more in common with each other than with their respective staffs. Advising Churchill at the summit of the

British system of intragovernmental planning was a war cabinet with which the chiefs of staff committee sat. While President Roosevelt could and did draw on the assistance of the war-born U.S. joint staff system, he never established anything remotely resembling the British war cabinet. The differences between the two politico-military systems—one loosely built, the other closely tied—were sometimes strikingly illustrated at the international war conferences.

The full-dress Anglo-American conferences usually came about when planning had reached a point where top-level decisions on important matters of Allied strategy and policy were necessary. The conferences and the CCS system provided the framework for the important decisions in European and Asiatic strategy. Decisions in the war in the Pacific against Japan were handled somewhat differently. The U.S. Joint Chiefs of Staff who were early given the responsibility for this war submitted their decisions on plans and operations against Japan to the conferences. There the combined chiefs usually gave their stamp of approval.

Beneath the top-level machinery, and funneling into it, was a whole network of specialized combined and joint planning agencies. At the bottom of the hierarchy lay the planning staffs of the individual services in the capitals. Unique among them on the American side was the War Department's Operations Division, which, under the army chief of staff, Gen. George C. Marshall, developed into the "Washington command post" to control the strategic deployment and activities of the army forces scattered all over the world. As the war progressed, the highly organized planning machinery in the capitals was supplemented by the big theatre headquarters staffs. Such theatre commanders as General Eisenhower in the European theatre and Gen. Douglas MacArthur in the Southwest Pacific began to play an increasingly important role in strategic decisions. The vast and speedy network of telecommunications circling the globe enabled strategic plans and decisions to be quickly made and executed. Never had the processes and machinery of strategic planning been so highly organized as in World War II.

Even though much of the Anglo-American discussions at the Arcadia Conference centred about the crisis in the Pacific, the western partners agreed that the first and major object of Anglo-American grand strategy must be the defeat of Germany. The principle of "Europe first" had actually been foreshadowed in staff conversations early in 1941. So had the corollary that, should Japan enter the war, military strategy in the East would be defensive. When war came to the United States in Dec. 1941, this strategy, despite the initial Japanese victories, was adopted.

Political expediency combined with geography and logistics in arriving at this decision—perhaps the single most important one made by the British and U.S. in World War II. British and Soviet power lay close to Germany. Great Britain offered a base for massing western air power; in the Mediterranean, operations against Germany could soon be undertaken. The Soviet Union and Great Britain could not wait for a decision in the war against Japan. Before the West could come to grips with Japan decisively, U.S. naval striking power would have to be restored, ships built, and advance bases and lines of communications extended across the far Pacific. It followed, therefore, that defeat of Germany should be the first major objective and that in the meantime the Japanese should be contained until the Allies could assemble enough strength to take the offensive in the Pacific.

The divergent approaches of the Allies were most clearly reflected initially in the conflict between U.S. and British strategy against Germany. The 1941-42 period saw the emergence of what may be called the peripheral theory, espoused by Churchill and the British staff, and the theory of mass and concentration, advocated by General Marshall and his staff. The British stood for hitting the German Army at the edges of the continent; the Americans, for concentration at the decisive point to defeat the main body of the enemy. In the peripheral concept, emphasis would be on swift campaigns of speed and maneuver, on probing soft spots, on a war of attrition. The cross-channel operation would follow as a last blow against a Germany already in process of collapse. The British concept was in accord with its small-scale economy

and limited manpower, its experience in World War I, and the prime minister's predilections. The U.S. early thought of defeating the German Army decisively. This view reflected U.S. optimism, reliance on the industrial machine to produce the necessary wherewithal, and military faith in a large citizen army built and trained for offensive purposes. Both justified their theories and plans as ways of relieving the pressure upon the Russians. The divergent approaches lay behind the debate in 1942 over the notion of an early cross-channel attack versus the invasion of North Africa—Operation Torch. The British won out, the president overruling the U.S. staff, and October saw the start of Mediterranean operations.

The Torch decision, which so disappointed U.S. military expectations, also complicated relations with the Soviet Union. Stalin, locked in a death struggle on the eastern front, demanded a second front—and soon. Each Anglo-American postponement of this second front was to add fuel to the fire of his resentment.

The cross-channel versus Mediterranean debate of midwar was argued in and out of the big international conferences. North Africa led to Sicily (July 1943); Sicily, to the invasion and surrender of Italy (Sept. 1943). Always the prime minister urged operations in the Mediterranean that would bleed the foe and prepare the way for an eventual cross-channel operation. Always the U.S.—with Marshall as the foremost spokesman—urged the need for a definitely scheduled cross-channel operation in force and for tapering the Mediterranean effort. Both sides agreed on the need for strategic bombardment to pave the way. The series of Anglo-American decisions reached at the 1943 conferences—Casablanca in January, Trident (Washington) in May, Quebec in August, and Cairo-Teheran in November and December—reflected the compromises between opportunism and long-range commitments, between a war of attrition and a war of mass and concentration.

The meeting at Teheran in Nov. 1943, where, for the first time in the war, the president, the prime minister and their staffs met with Marshal Stalin and his staff, was the decisive conference for strategy. Churchill made eloquent appeals for operations in Italy, the Aegean, and the eastern Mediterranean, even at the expense of a delay in the cross-channel invasion—Operation Overlord. But Stalin, for reasons of his own, put Soviet weight squarely behind the U.S. concept of strategy. He asserted his full power as an equal member of the coalition and came out strongly in favour of Overlord. Further operations in the Mediterranean, he insisted, should be limited to the invasion of southern France in support of Overlord. In turn, he promised to launch an all-out offensive on the eastern front.

Stalin's stand put the capstone on Anglo-American European strategy and in a sense fixed western strategy. Germany was to be crushed by a great pincers—the Anglo-American drive on the west and a Soviet drive from the east. General Eisenhower was appointed commander for Overlord, and preparations for the cross-channel thrust began. The decision at Teheran marked a subtle but significant change in the relationship of the Allies. Britain was growing relatively weaker, the United States and the Soviet Union stronger. By way of the military doctrine of concentration the strategists of the Pentagon and of the Kremlin had found common ground.

The third phase of the strategy story—from the summer of 1944 to the surrenders of Germany and Japan—was the period of the payoff. In this period the problems of winning the war began to come up against winning the peace. The curtain began to lift on the divergent national objectives of the Allies—objectives hitherto obscured by the common military danger. The western drive unfolded according to plan. The thrust across France coincided with the invasion from the Mediterranean; the Rhine was crossed, the Ruhr encircled, and the drive across Germany met up with the Russian advance. But to Churchill, warily watching the swift Soviet advance into Poland and the Balkans, the war had become more than ever a contest for great political stakes. As the strategy unrolled in the field, the two approaches to the war boiled down to a question of military versus political maneuvers.

While the war in the West was drawing to a close, the strategy for defeating Japan had been taking gradual shape. As the war

had advanced, Allied strategy in the Pacific shifted from the defensive to the offensive. Though firm, final plans had to await the defeat of Germany, the momentum of advances in the Pacific was so fast that it almost caught up with the European conflict. Island to island advance was gradually changed to island-hopping. The Battle of Midway in 1942 foreshadowed a new trend in naval strategy, in which opposing fleets did not get within gun range of each other, but duelled with their air power and submarines. Submarine warfare, amphibious assaults, task forces built around aircraft carriers, the strengthened American fleet—speeded the pace in midwar. A twofold approach—along the southwest and central Pacific axes—took the Allies to the threshold of Japan by the time the European war closed. Before final plans for invasion were put into effect, however, the Japanese surrendered. A multiplicity of factors led to this result—including the threat of invasion, the attrition of Japanese shipping, air bombardment, the entry of the Soviet Union into the war against Japan, and the dropping of two atomic bombs.

In retrospect, the strategy of World War II represented a curious mixture of old and new strands. Never had strategy had so vast a scope, for this was the first really global war. Never in history had two partners pooled their efforts and ideas so closely as had the Americans and British in the grand alliance. Once more the scales of war were tipped in favour of the offensive. To the age-old primary aim of seeking the defeat of the enemy's armed forces was added the objective of striking at his industrial heart. Both these aims, for example, were present in the directive given to General Eisenhower for the European campaign. In Pacific strategy, it long remained a question whether invasion and defeat of the enemy forces on their home grounds would even be necessary. Strategic bombardment and sea power gave support for a strategy of attrition and destruction of industrial capacity. But the thesis that the sole aim of strategy was to support air power in order to annihilate the enemy's industrial power was only partially tested. It had been impossible to put all production and manpower into the air strategy. Nor were ground and sea enthusiasts on the basis of World War II experiences disposed to yield the field of strategy completely to the new arm. Allied military strategy, despite attention to "principles," had been a hybrid product, largely hammered out on the anvil of necessity. Final answers in military strategy to the problems of proper aims and emphases, and of best combinations and permutations, were still not clear.

It was clear, however, that modern war had grown more total than ever, and that science, industry, diplomacy, and psychology all had to be harnessed to it. Campaign strategy could no longer be clearly differentiated from national strategy; military strategy—in the sense of disposing armed forces for battle—was overshadowed by grand strategy. Where all this would lead was still not clear at the end of World War II, for hanging over all society was the weapon that threatened to revolutionize all warfare, the atom bomb.

**7. Cold War in the Nuclear Age.**—A great debate over strategy arose in the postwar years. Underlying it were a number of crucial factors. World War II had further upset the balance of power in the world, earlier disturbed in World War I. Germany and Japan had been defeated, Britain and France further weakened, and the United States and the Soviet Union had emerged as the two strongest powers in the world. The growing rift between the East and West led some critics in the Western world to point to mistakes in Allied political and military strategy of World War II—especially to an overconcentration on military objectives at the expense of political aims, on gaining military victories rather than winning the peace. While part of this criticism seemed overly harsh and not always founded on well-established fact, it was clear from the growing flood of literature on World War II that political and military strategy in World War II had not been systematically meshed. At the same time the war had loosed a wave of nationalistic and revolutionary movements in the world with strategies of their own. The struggle by the committed powers to win the non-committed was intense. Through coordinated political, economic, military, and psychological pressures, the Soviet Union sought to incline the new nationalistic and revolutionary movements toward

its orbit. The growth of the cordon of Soviet satellite states in central and eastern Europe was one result of its postwar strategy; the Soviet link with Red China was another. Meanwhile the West, led by the United States, moved to shore up the weakened European powers. The Truman Doctrine, the Marshall Plan, and the emergence of the North Atlantic Treaty Organization (NATO) were diverse strategic weapons to counter the many-sided Soviet threat. The cold war moved strategy to all fronts—political, diplomatic, economic, propagandistic, as well as military—in both the East and West. New phrases entered the vocabulary of Western thought—"strategy of containment," "strategy of total war," "massive retaliation," "preventive war," "deterrence," "graduated deterrence," and "escalation" (increase in scope of a conflict).

Though the great concern in the cold war era was the possible outbreak of World War III, strategy also had to consider limited warfare. The Korean War (*q.v.*) brought the North Korean and Chinese Communist forces into conflict with the South Korean and United Nations forces. It demonstrated that warfare in the cold war could also be limited and "hot," and that strategy would have to be tailored to local as well as worldwide needs.

Meanwhile, on the military plane, the impact of science and technology on warfare was promising revolutionary changes in strategy. To the growing arsenal of powerful new weapons begun with the invention of the atom bomb was added the hydrogen bomb—a bomb that could wipe out a whole city. New developments such as atomic-powered air and naval craft, atomic artillery, guided missiles that could cross oceans and continents, chemical, biological and radiological weapons, supersonic speeds, and other revolutionary adaptations in communication and transportation pointed to many changes in the art of war and in strategy. A great debate was joined between those who placed primary reliance on the new methods and means of war, and those who championed more orthodox and conventional approaches supplemented by the new weapons. The debate was particularly sharp between the advocates of a national military strategy based upon air power alone and the defenders of traditional strategy. Some air enthusiasts felt that the defeat of an enemy's armed forces on the battlefield was no longer a primary aim of strategy; that a new atomic air strategy offered unparalleled opportunity to break an enemy's will to resist by paralyzing his industrial power. Some advocates believed that the new atomic air strategy could be superimposed on the old strategy based on land, sea, and air forces; others believed that a choice had to be made between the two. Inevitably, the new developments in warfare also led authorities to take a fresh look at the "principles of war." Some began to argue that dispersion rather than concentration had become a basic goal; others argued that concentration merely required new adaptation.

Still other theorists in the cold war period were pointing up other new trends in strategy. Some went so far as to assert that not only was conventional military strategy outmoded but, along with it, national strategy. This belief was based on the idea that the 20th century was the age of great coalitions. This condition had resulted from the shrinkage of the world, the growing interdependence of nations, and the nature of modern war.

Western theorists were groping to comprehend the implications of the new environment of strategy—the revolutions in technology, the rising expectations of the many new nations, exploding populations, the threat of national and international Communism, and the tensions among the Communist countries, especially China and the U.S.S.R., that became apparent in the 1960s. They were probing the options between coalition strategy and national policy; the impact of domestic budgets and politics in legislating strategic programs, the relations between the nuclear deterrent and civil defense, and the effect of the nuclear stalemate in encouraging limited or unconventional warfare. Beyond the growing complications of the earthbound world arena lay outer space, which man was beginning to explore, and theorists were beginning to reckon with the future possible military implications of space technology. The realization was growing that deterrence in the cold war must be as wide as the spectrum of conflict in all its possible forms and intensities. More and more attention was being given to "balanced," "integrated," and "flexible" strategy, and to a comprehensive

sive system of deterrence—to tailor means to the particular threat and to give political leaders wider range of freedom of action. More attention was given to the theory and practice of so-called brush-fire wars, of wars of subversion, and of guerrilla and counter-guerrilla warfare.

At the same time, strategy, it was felt, must be waged primarily with political, economic, and propagandistic means. Preparedness on all fronts—military and nonmilitary—became a significant factor in that strategy. The belief seemed to be growing that in the holocaust of all-out modern war all sides would lose. The ultimate aim of strategy in the cold war had become the achievement of national and international objectives without touching off World War III. Strategy had expanded into every phase of national endeavour, just as had war itself. The line of demarcation between war and peace had further broken down, and with it the broadest definitions of strategy yet offered were no longer adequate. From the stratagems of the commander in war, strategy had come to preempt more and more of the spheres of warfare and diplomacy. The line dividing it from policy had become indistinct, and its highest aim had become the defense and survival of civilization itself. See also ECONOMIC WARFARE; LOGISTICS; compare, for further analysis of modern issues and dilemmas, INTERNATIONAL RELATIONS; also PEACE, INTERNATIONAL; WAR; and DISARMAMENT; and references under "Strategy" in the Index.

**STRATFORD, JOHN** (d. 1348), archbishop of Canterbury (1333–48) and chancellor of England (November 1330–September 1334, June 1335–March 1337, April–June 1340), a leading counselor of the English king Edward III, was born at Stratford-upon-Avon, Warwickshire, and educated at Oxford University. By 1322 he was canon of York and of Salisbury, archdeacon of Lincoln, and in June 1323, while visiting Avignon, he was consecrated bishop of Winchester by Pope John XXII. Stratford, a doctor of civil law by 1312, gave legal advice to Edward II's council from 1317 and was a royal clerk by 1320. Stratford offered to mediate between Edward and Queen Isabella on her return from France in 1326, but he later drafted the so-called Articles of Deposition and helped to force Edward to renounce the throne. Although a counselor to the young Edward III, Stratford was opposed by Roger Mortimer and his ascendancy began only after Mortimer's fall (November 1330). Chancellor for about six of the following ten years and archbishop of Canterbury from 1333, Stratford accompanied Edward to France, Flanders, and Scotland. After the outbreak (1337) of the Hundred Years' War, Stratford had difficulty in providing the king with adequate financial supplies and in October 1339 and January 1340 failed to get a grant from Parliament. He was probably guilty of some mismanagement. Edward returned suddenly to England from Flanders in November 1340 and arrested many officials. John's brother Robert, who had succeeded him as chancellor, escaping only because he was a bishop. John retired to Canterbury, where he used his pulpit to rebut the charges made against him and at the Parliament of April–May 1341 he skilfully achieved a reconciliation with Edward. He did not regain his former influence, however. He died at Mayfield, Sussex, on Aug. 23, 1348, and was buried in Canterbury Cathedral.

See A. B. Emden, *A Biographical Register of the University of Oxford to A.D. 1500*, vol. iii (1959).

**STRATFORD DE REDCLIFFE, STRATFORD CANNING, VISCOUNT** (1786–1880), British diplomat notable for his influence in Turkish affairs, was born in London on Nov. 4, 1786, the fourth son of Stratford Canning, a merchant who had been disinherited following his marriage to Mehitabel Patrick. The elder Canning died in April 1787, endowing his family with little but the friendship of his nephew, George Canning (*q.v.*). The latter's influence enabled Stratford Canning to be educated at Eton and King's college, Cambridge. His studies there were interrupted when George Canning, then foreign minister, appointed him in 1807 as a *précis* writer at the foreign office and later to missions at Copenhagen and Constantinople. In 1810 he became *chargé d'affaires* at Constantinople and, without instructions from England, helped arrange the peace of Bucharest (1812) between Turkey and Russia, just as Napoleon was about to invade the latter. On returning home, poverty thwarted his ambition to enter political life, but Lord Castlereagh appointed him minister to Switzerland (1814–18) and used him at the Congress of Vienna as adviser on that country. He then went as minister to Washington (1819–23) and, although he sometimes clashed with John Quincy Adams, the U.S. secretary of state, on returning to London he negotiated a convention which was, however, refused ratification by the U.S. senate.

In 1824 George Canning appointed him ambassador at Constantinople, but sent him first to discuss North American frontier questions at St. Petersburg. He also raised, unofficially, the Greek issue. At Constantinople he joined the Russian and subsequently the French ambassadors, but the battle of Navarino (*q.v.*) on Oct. 20, 1827, forced all three to retire to Corfu. In 1828–29 Canning resumed negotiations concerning Greece at a conference at Poros and accepted an extension of its frontiers, which was however repudiated by the earl of Aberdeen, then foreign minister. Lord Palmerston sent him again to Constantinople in 1831, when he finally obtained these frontiers, chiefly because of the threat to the sultan from Mohammed Ali (*q.v.*), the pasha of Egypt. Palmerston, whom the cabinet prevented from accepting Canning's advice to protect the sultan, next appointed him ambassador to St. Petersburg. The tsar Nicholas I, for reasons still not completely explained, refused to receive him, so that henceforward there was a personal issue between the two.

During this controversy Stratford Canning was sent on a special mission to Spain (1832–33) which was not a great success, and then embarked on a political career. He had sat for the pocket borough of Old Sarum (1828) and Stockbridge (1831), both abolished by the Reform bill, and 1835–41 was member for King's Lynn, speaking in the house mainly on foreign affairs. He impressed little and although in 1851 Lord Stanley promised that he should be the next Tory foreign minister, Canning was never to hold office. Meanwhile he had accepted a fourth mission to Constantinople (1841–46), when he established a unique position of influence over the sultan and his ministers, and tried hard without much success to reform the Ottoman empire. Palmerston afterward dispatched him on missions to Switzerland and central Europe, and then began another period at Constantinople (1848–51), when he supported the sultan in retaining Polish and Hungarian refugees. Created viscount in 1852 he was reappointed (1853–58), and thus served throughout the Crimean War (*q.v.*). Contrary to the view often held by historians, research has shown that, though he saw the danger of the demands of Nicholas I, he worked for a peaceful solution but was thwarted by refusal of the sultan to accept his advice. During the war he strove to improve hospital and army administration. He was in continual controversy with the French, jealous of his influence which in fact declined over this period. Nevertheless he was given a magnificent farewell from Constantinople in 1858.

In 1816 Canning married Harriet Raikes (d. 1817) and in 1825, Eliza Alexander. From 1858 he lived quietly, occasionally speaking in the lords and publishing a few poems and books of devotion. He became a knight grand cross of the Bath in 1829, and received the Garter in 1869. He died on Aug. 14, 1880, in Frant, Sussex.

**STRATFORD-UPON-AVON**, a municipal borough in the Stratford parliamentary division of Warwickshire, Eng., 24 mi. S.S.E. of Birmingham and 91 mi. N.W. of London by road. Pop. (1961) 60,364. Area 10.8 sq.mi. It stands mainly on the left bank of the river Avon at the point where it is crossed by a 14-arch stone bridge presented by Sir Hugh Clopton in the reign of Henry VII; there is also a 19th-century bridge. As *Æt-stretfordae* (signifying "the ford by which a Roman road crossed the river"), Stratford was mentioned as early as 691. The manor was granted by Offa to the bishopric of Worcester; and it was under the protection of the bishops of Worcester that the inhabitants of the town early assumed burghal rights. The Gild of the Holy Cross, founded in the 13th century for the support of poor priests and others, exercised authority over the town for many years. Its dissolution was the cause of the incorporation charter of Edward VI in 1553. Another charter, altering the constitution of the corporation, was granted in 1611. Other charters were granted in 1664 and 1674.

Stratford is a picturesque market town and road centre and has one or two industries, but its world fame arises from its connection with William Shakespeare, born there in 1564 and whose plays and sonnets contain many allusions to local scenes. Relatively little is known of Shakespeare's life, so that the few genuine local traditions have, as is understandable with so famous a man, become encrusted with picturesque legend. It was not until 1769, when David Garrick inaugurated the first of the annual birthday celebrations, that any attempt was made to preserve buildings and other memorials of Shakespeare's life in the town, but many valuable links had already vanished.

Shakespeare was born in a half-timbered house in Henley street, bought by public subscription in 1847 and later handed to the care of the Shakespeare Birthplace trust. Here are gathered a number of documents and relics and an early portrait of him. He attended the grammar school adjoining the chapel built in the 13th century by the Gild of the Holy Cross and rebuilt in the 15th century. The chapel has a well-restored medieval Doom painting and there is a reference to a schoolmaster there as early as 1295. The hall was used from time to time by traveling companies of actors and it may have been that in this room Shakespeare had his first introduction to the stage. In 1597 Shakespeare bought the house known as New Place, and there he died in 1616. The house was pulled down in 1759, and only the foundations remain. By it is Nash's house, a museum of both local and Shakespearean relics.

Shakespeare's grave is in Holy Trinity church, a fine cruciform building on the site of a monastery that existed before 691. The earliest parts of the church (transepts, tower and parts of the nave walls) date from 1189 to 1272; the aisles are Decorated; the chancel is Perpendicular. Here is the font in which it is said Shakespeare was baptized, and the chancel where he is buried, beside his wife and other relatives. On the adjoining wall is a monument with the well-known bust of Shakespeare by Gerard Johnson (Janssen).

The group of buildings by the river known as the Shakespeare Memorial comprise a library and art gallery (opened in 1881)—all that was left of the original memorial built in 1879—and a theatre (opened in 1932) designed by Elisabeth Scott to replace that destroyed by fire in 1926. The Memorial houses a valuable collection of Shakespeareana, including early folio editions of the plays and the famous "Droeshout print" of Shakespeare which was a frontispiece to the *Plays* of 1623. The library (10,000 vol.) is one of the most complete of its kind.

April 23—the date of Shakespeare's death and, approximately, also of his birth—is annually celebrated with a procession attended by distinguished representatives of many nations, and every year from March until October is the Shakespeare festival when his plays are acted at the Memorial theatre.

Hall'scroft, a Tudor building with rare old furniture, was the

home of John Hall, Shakespeare's son-in-law. The Quiney house was the home of Judith Shakespeare, the poet's youngest daughter; Harvard house (1596) was the girlhood home of the mother of John Harvard who endowed Harvard university in the United States. It is one of the few notable buildings (such as the 18th-century Town hall, Shrieve's house, rebuilt 1614, and Emmi's court, dating from the 17th century) which are not connected with Shakespeare. Masoncroft became in 1951 the Shakespeare institute of Birmingham university. At Shottery, 1 mi. W., is the thatched cottage which was the early home of Shakespeare's wife, Anne Hathaway. It was bought for the nation in 1892.

The poet's mother was Mary Arden, the name of an ancient county family that survives in the forest of Arden, which formerly covered a large area northwest of Stratford. Her birthplace, a Tudor farmhouse at Wilmcote (about 5 mi. N.W.), is preserved as a museum, and it has a collection of local farming implements.

**STRATHAVEN** (local pronunciation "Straven"), an upland manufacturing and market town in Avondale civil parish, Lanarkshire, Scot., on the Avon, 8 mi. S. of Hamilton by road. Pop. (1951) 4,288. It is the centre of a dairy-farming and pastoral country; industries include textiles (silk and hosiery), grain milling, agricultural engineering, printing and motor-coach building. The ruins of Avondale castle, which commanded the route into central Ayrshire, stand on a crag above Powmillion burn. At Drumclog, 6 mi. S.W., a school and a granite obelisk commemorate a victory of the Covenanters over Graham of Claverhouse on June 1, 1679. (G. P. I.)

**STRATHCLYDE**, the name given in the 9th and 10th centuries to the north British kingdom, which from the 6th century onward was probably confined to the basin of the Clyde, together with the adjacent coast districts, Ayrshire, etc., on the west of Scotland. Its capital was Dumbarton ("fortress of the Britons"), then known as Alclut. On the north the kingdom bordered on the Scots of Dalriada (q.v.), and on the south on the Cymri (Lat. *Cumbri* or *Cumbrenses*, "Compatriots"), the name used by English writers since the 10th century to include Strathclyde, and surviving in the English Cumberland and in the Welsh name for themselves, *Cymry*. All were survivors of the British (Welsh) population, speaking one language (Welsh) and recognizing a common kinship, and the Cumbri extended southward into Lancashire and probably east of the Pennines. No vernacular written records survive from the Cymri, but much information about them is available from Scottish, Irish, and Saxon records, and from later Welsh literature derived from Cumbric oral tradition. Important for the early period are the *Historia Brittonum* of Nennius, the *Annales Cambriae*, the genealogies, and early Welsh poetry.

During the late Roman period the Cumbri emerge as a loose confederation of independent local princes, policing the northern frontiers of Roman Britain against Pictish aggression. Preeminent among them was the Strathclyde dynasty of Dumbarton which included Ceretic Guletic, generally identified with the Coroticus to whom St. Patrick's famous *Epistola* was addressed, and ancestor of Rhydderch, St. Columba's contemporary. Welsh tradition also records the arrival in the 5th century in North Wales from Lothian of a famous chief Cunedag (Cunedda) and his sons to dislodge Irish settlers. By the early 6th century Christianity was widely established in Cumbria. In the second half of the century the Cumbrian princes, including Rhydderch and a famous heroic chief Urien, probably from the Solway area, waged aggressive warfare against the Bernicians, while in 642 Owain, king of Strathclyde, defeated and killed the Scottish king of Dalriada, Domnall Brecc.

During the reign (641–670) of the Northumbrian king Oswiu the Anglian kingdoms established a supremacy over all Cumbria except Strathclyde, which maintained its independence till the year 756 when the kingdom suffered a crushing defeat from the Northumbrian king Eadberht and the Pictish king Angus mac Fergus. In 870 Vikings plundered and destroyed Dumbarton. Nevertheless, in 878 Eochaid of the Dumbarton dynasty seems to have gained a control over Dalriada lasting for 11 years; and some expansion of influence is traceable till 920 or 921 when the Anglo-Saxon king Edward the Elder, and in 927 his successor Aethelstan.

received the submission of the Britons of Strathclyde, the Scots, the Bernicians, and the Danes of York. In 937 Strathclyde joined with the Scots and Norsemen in a combined attempt to overthrow the English supremacy, but were defeated at the Battle of Brunanburh.

During the first half of the 10th century kings were still reigning in Strathclyde; but in 945 the English king Edmund I harried the kingdom and leased it to Malcolm I, king of the Scots, who was thus the first Gaelic king to rule the Britons in southern Scotland. In 971, however, the Strathclyde Britons invaded Lothian, having evidently regained their independence, which they maintained under their own kings till the early 11th century. In c. 1016 (or 1018?) Owain of Strathclyde united his forces to those of Malcolm II, king of the Scots, in a triumphant campaign against the Anglian kingdom of Lothian, which ended in the overwhelming defeat of the English at the Battle of Carham. Owain died soon afterward, the last independent king of Strathclyde. Henceforth the ancient kingdom of Cumbria became a province of Scotland.

**STRATHCONA AND MOUNT ROYAL, DONALD ALEXANDER SMITH, BARON** (1820-1914), Canadian fur trader, financier, railway promoter, and statesman. Born at Forres, Scot., Aug. 6, 1820, he was apprenticed to the Hudson's Bay Company in 1838 and, after serving at Lachine and Tadoussac for ten years, he was sent to Labrador, where he rose to the rank of chief factor. In 1870 he was appointed chief commissioner for the company in Canada, but relinquished this office in 1874 to head the land department. After becoming the principal shareholder, he was governor of the Hudson's Bay Company from 1889 until his death in London, Jan. 21, 1914.

In 1869 he represented the Canadian government in negotiations with the Red River insurgents for the peaceable transfer of the Hudson's Bay Company territory to Canada. A Conservative member of the new Manitoba legislature, 1870-74, he was elected to represent Selkirk in the Canadian House of Commons in 1871. By withdrawing his support of Sir John A. Macdonald during the Pacific Scandal, 1873, he contributed to the defeat of the Conservative ministry. With his cousin, George Stephen (later Baron Mount Stephen), and others, he successfully promoted the St. Paul, Minneapolis and Manitoba Railway, but because of Macdonald's antipathy he was not formally a member of the syndicate formed to build the Canadian Pacific Railway in 1880. Nevertheless his financial support was vital to the enterprise and he was accorded the honour of driving the last spike at Craigellachie, B.C., in 1885. He became president of the Bank of Montreal in 1887, and honorary president in 1905.

Defeated in Selkirk in 1880, he represented Montreal West in the House of Commons, 1887-96, but retired to become Canadian high commissioner in London, 1896-1914. Founder of Royal Victoria College for women at McGill University, he was elected chancellor of the University, 1889, and of Aberdeen University in 1903. He equipped and maintained Lord Strathcona's Horse in the South African War. Knighted in 1886, he was raised to the peerage in 1897.

See W. T. R. Preston, *The Life and Times of Lord Strathcona* (1914); Beckles Willson, *The Life of Lord Strathcona and Mount Royal* (1915). (A. R. Tu.)

**STRATHNAIRN, HUGH HENRY ROSE, 1ST BARON** (1801-1885), British field marshal, the ablest of the galaxy of commanders who suppressed the Indian Mutiny (*q.v.*), was born on April 6, 1801, in Berlin. Commissioned in the 19th Foot (1820), he saw active service in Syria while on a mission to the Turkish Army, then opposing Mohammed Ali of Egypt. Under his regime as consul general in Syria (1841-48) order was restored, justice honestly administered, and tribal feuds repressed. In 1851 he became secretary to the embassy at Constantinople. Appointed British liaison officer at French headquarters he was present at all the battles of the Crimean War (1854-56). He was promoted major general in 1854.

At the beginning of the Indian Mutiny (1857) Rose was appointed to command the Central India force of two brigades and conducted the most difficult, vigorous, and successful operations of the war. After storming the fort of Rahatgarh (January 1858); he relieved Sagar (Feb. 3), captured the fort of Garhakota, forced the Malthon Pass, and seized Chanderi (March 7). These successes enabled him to lay siege to Jhansi, the principal hostile stronghold of the area, and despite the vigorous resistance of the garrison under the widowed rani of Jhansi, it was carried by assault (April 3-4) after a relieving army under Tantia Topi had been routed. Fierce heat rendered the operations toilsome and costly in losses from sunstroke and prostration; but they were pursued with vigour, and the enemy was driven from Kunch and from Kalpi. The campaign seemed over when Rose heard that the rani of Jhansi and Tantia Topi had seized Gwalior, the strongest fortress in central India, having won over the troops of its ruler, Sindhia. Rose at once moved against it and carried it by assault. He then took command of the Poona Division (June 1858) and later of the Bombay army (1860), with the delicate task of amalgamating the queen's and the East India Company's forces in that province. Returning to England in 1865, he was appointed commander in chief in Ireland (1865) and raised to the peerage (1866). He died, unmarried, in Paris on Oct. 16, 1885.

See O. T. Burne, *Clyde and Strathairn* (1891). (E. W. Sh.)

**STRATHSPEY**, a Scottish type of slow dance tune in common (4/4) time, characterized by frequent use of the "Scotch snap"; i.e., a dotted quaver preceded by a semiquaver. Strathspeys appear to have originated c. 1700 in the valley (Scots: *strath*) of the River Spey. After c. 1745 strathspeys came into general use throughout Scotland as tunes for reels and country dances. See REEL. (T. M. Fl.)

**STRATIFICATION**, as a term applied to rocks, refers to their layering. Strata or layers are distinctive features of most sedimentary rocks and are common also in those igneous rocks formed at the earth's surface—lava flows and volcanic fragmental deposits. No connotation of thickness is implied by the term and individual layers or strata may range from a fraction of an inch to many feet. Likewise the shapes of individual strata vary greatly according to the type of rock and the conditions of deposition. They range from thin sheets that cover many square miles to thick, lenslike bodies extending only a few feet laterally.

In sedimentary rocks the term stratum is not synonymous with the terms bed or lamination, although some geologists have used it in that sense. Both bed and lamina carry definite thickness connotations, beds referring to rock layers greater than one centimetre in thickness and laminations to layers that are one centimetre or less in thickness. Thus, both beds and laminations are varieties of strata; likewise bedding and lamination are terms restricted to stratification having definite thickness limitations.

Planes of parting or separation between individual rock layers commonly are referred to as stratification planes. They tend to be even and to be parallel to the strata that they bound, for they are essentially horizontal where sediments are deposited as flat-lying layers and they slope correspondingly where the deposits are laid down with an initial dip. Notable exceptions to the evenness of stratification planes develop where deposition takes place on irregular surfaces. In such situations the bottom surface of a stratum normally conforms roughly to the irregularities of the underlying surface, but the stratification plane above the stratum will tend to be nearly horizontal. In many places original, nearly horizontal surfaces of stratification planes have subsequently been destroyed by erosion during pauses or breaks in sedimentation.

Stratification in sedimentary rocks may result from changes in texture or in composition during deposition of the sediment; it also may result from pauses in deposition that allow the first deposits to undergo certain changes before additional sediments cover them. A sequence of strata, therefore, may appear as alterations of coarse and fine particles, as a series of colour changes resulting from differences in mineral composition or merely as layers of similar aspect, separated by distinct planes of parting. No direct relationship exists between the thickness and extent of

strata and the rate of deposition or time represented; for example, a 1-in. stratum of limestone may take longer to form than a 10-ft. stratum of sandstone.

The most frequent cause of stratification is variation in velocity of the depositing agent. During transportation water and wind sort sediments according to size, weight and shape of particles and these sediments settle in layers of relative homogeneity. A second cause is differences in composition of sediments from different sources, illustrated by successive floods spreading over a floodplain from several tributaries of a river. Still another cause is variation in sediment brought about by change in agents of deposition, as where muds of a delta plain are covered by wind-blown sands, or where limy ooze of the sea floor is buried beneath ash of a volcanic eruption. Thus, variations of any type that affect the uniformity of sediment being deposited result in stratification.

Stratification in sedimentary rocks varies greatly both in degree of prominence and in details of structure. In general, it is best developed in fine-grained sediments and is least apparent and least persistent in coarse-grained materials such as conglomerates. Two important and distinctive structural types are recognized as characteristic of particular environments. These types are: (1) current bedding or cross-stratification in which layers have been deposited at one or more angles to the original dip of the formation; and (2) graded bedding in which particles grade upward in a stratum from relatively coarse at the bottom to relatively fine at the top.

Cross-stratification is the product of deposition by wind or water currents as they lose velocity, whereas graded bedding results from simultaneous settling of coarse and fine sediments in waters of a comparatively quiet bottom.

Cross-stratification, which may consist of medium to thick layers (cross-bedding) or of very thin layers (cross-lamination), includes many variations, the most basic of which are the simple, planar and trough types. Simple cross-stratification involves sets of sloping layers formed by deposition only; planar cross-stratification results from alternating deposition and partial planation of the strata; trough cross-stratification, from deposition together with scouring or channeling. Cross-stratification is developed in a number of different depositional environments including the fronts of deltas, the lee sides of dunes, the channels of rivers and streams and various other places where initial dip is a characteristic feature. Commonly the nature of this environment can be recognized by analysis of the structures.

Graded bedding is typical especially of dark sandstones or graywackes and of conglomerates formed in areas of relatively rapid sedimentation under unstable crustal conditions that characterize the rapid sinking of a geosyncline or depositional trough. Under such conditions thick sequences of graded beds may accumulate. The mixing of coarse and fine particles has been attributed to submarine temblors (earthquakes), to movement by density currents down steep slopes and to other causes.

Seasonal deposits or varves of glacial lakes are another kind of graded bedding. In them light-coloured silt grades upward into dark-coloured mud forming a couplet a few millimetres thick. Each such couplet is the deposit of a single year and is separated from other, similar couplets by an abrupt change in colour.

Stratification in volcanic rocks differs in some respects from that in sedimentary rocks. Fragmental volcanic material, thrown into the air during violent eruptions, becomes stratified in flight under the influences of gravity and wind. Falling to the ground, it may form well-sorted layers. If it falls into lakes or the sea, it becomes layered like any other water-borne detrital matter; however, when a mixture of coarse, volcanic debris full of gas bubbles (pumice) and fine ash falls into quiet water, reverse graded bedding may result, with the finer but heavier grains at the bottom grading up into the coarser, lighter fragments. Stratification also may result from successive outflows of liquid lava or alternations between lava flows and ash falls. False stratification sometimes develops in flows due to contraction on cooling.

Not all sedimentary deposits are stratified. Those transported by ice, either pushed ahead of a glacier or carried by it, form

unlayered deposits called till. They are piled up or dumped as the ice melts, forming moraines and other features lacking stratiform structure. Likewise materials accumulated through the force of gravity, such as talus deposits at the bases of cliffs and landslides, may exhibit no sorting and no stratification. Still other deposits are structureless because original stratification has been destroyed through the work of plant roots, or the borings of worms and various other animals, or by recrystallization. Residual soils and reefs built by organisms likewise have no stratification.

Stratification is one of the geologist's most useful tools. Its structure provides a clue to the environment in which the sediment or igneous material accumulated. Furthermore, where once horizontal layers have been deformed, the record of past earth movements is preserved in the stratification. Folding, faulting and other forms of disturbance commonly are recorded by tilted or broken strata and these make possible the interpretation of geologic events. From this record such practical results as the location of mineral deposits, petroleum fields and ground water are obtained.

See also SEDIMENTARY ROCKS; GEOLOGY. (E. D. McK.)

**STRATIGRAPHY** is concerned with the sequence of strata formed in the earth by sedimentation (e.g., from water, wind, ice, volcanoes, and human activity). Closely coordinated with petrology and paleontology (*qq.v.*), stratigraphy provides a basis for historical geology (the history of the earth's surface).

Leonardo da Vinci appreciated the concept of stratigraphy, but the scientific foundations were laid during the 19th century in England by Sir Roderick Impey Murchison, Adam Sedgwick, and William Smith (*qq.v.*); in Germany by A. G. Werner and F. A. Quenstedt; in Bohemia by J. Barrande; and in North America by Charles Schuchert. Since the upper of two layers usually has been deposited last (the so-called law of superposition) an age sequence can be established directly unless tectonic movements (e.g., upheavals such as faulting, thrusting, and folding) have disturbed the sequence. In the analysis of such complicated cases the fossils contained in the strata are of paramount importance since different forms of life have been found to characterize specific periods of geologic time.

Thus investigations first delineated the stratigraphical sequence for the last 500,000,000 years, during which there was abundant life and many plants and animals were equipped with hard structures that are readily fossilized.

This sequence was divided into three major eras or groups, the Paleozoic, the Mesozoic, and the Cenozoic, each subdivided into periods or systems. The Paleozoic Era (divided into Cambrian, Ordovician, Silurian, Devonian, Carboniferous, and Permian periods) is known from the evidence of radioactivity to have lasted approximately from 500,000,000 to 200,000,000 years ago; the Upper Carboniferous was the time when coal was formed in swamp forests. The Mesozoic Era (divided into Triassic, Jurassic, and Cretaceous periods) lasted from about 200,000,000 to 70,000,000 years ago and was the time of dinosaurs and ammonites (*see* AMMONITE); in the Upper Cretaceous the chalk of Britain was laid down as a mud containing the skeletal remains of minute animals in the sea. The Cenozoic Era (divided into Tertiary and Quaternary or Pleistocene periods) covered the last 70,000,000 years (Pleistocene only 1,000,000); the Tertiary was the age of mammals; the Quaternary is the age of man.

These periods have been further subdivided into numerous epochs. Many were characterized by zone fossils that lived for only a brief time in many parts of the world; these made long distance, even intercontinental, correlation possible.

Investigation of Precambrian times is aimed at establishing a sequence back to the origin of the earth's crust, roughly covering the last 3,500,000,000 to 500,000,000 years. Three eras are distinguished: the Proterozoic (Precambrian or Algonkian), the Archaean, and the Azoic. The Proterozoic has yielded fossils of organized forms of life; the Archaean indirect evidence of life; and the Azoic is the period before life appeared. The subdivisions of the Precambrian eras are based on breaks in the sequence produced by earth movements that served to identify specific periods in time.

The most recent application of stratigraphy has been to archaeology. The earlier part of prehistory, covering Paleolithic man living during the Pleistocene, is marked by fossil remains of man and his stone artifacts. When a site is excavated, details of stratification indicate climatic sequences into which the prehistoric industries can be fitted. Post-Pleistocene sites containing the products of early man are carefully excavated according to layers, starting from the top. The layers are studied to ascertain their petrological composition and the fossils they contain are identified and interpreted. The tells (occupation mounds) of Eastern countries (e.g., ancient Jericho) have been investigated in this manner. These mounds consist of man-made deposits, later generations building their houses on the debris of earlier habitations (see ARCHAEOLOGY: *Mesopotamia: Stratigraphy and Relative Chronology*).

Archaeological stratigraphy has the advantage that tectonic disturbance is rare, but higher strata tend to cut into those below and the composition tends to be uniform throughout the sequence. Consequently, petrological methods are increasingly employed. See also GEOCHRONOLOGY; GEOLOGY; also references under "Stratigraphy" in the Index.

**STRATO OF LAMPISACUS** (d. c. 270 B.C.), Greek philosopher, became head of the Peripatetic school in succession to Theophrastus. As the main subject of his writings, apart from logic, was natural science, he was called Strato Physicus in antiquity.

Strato's theory was a combination of Aristotelian and atomistic elements. Thus he taught with Aristotle that there is only one world, instead of many; but he abandoned his master's teleological interpretation of nature and his hypothesis of a fifth element. The insistence on causality and the materialism that he shared with the atomists led him not only to remove every theological element but also to deny the immortality of the human soul.

Strato's writings as a whole are lost, but in antiquity he was highly esteemed and influential. His doctrine that all substances contain void and that differences in the weight of substances are caused by differences in the extension of void served as the theoretical base for the Hellenistic construction of air- and steam-engines as described in Hero of Alexandria's book.

See the fragments ed. by F. Wehrli, *Straton von Lampisakos* (1950), being part v of *Die Schule des Aristoteles: Texte und Kommentar*; G. Rodier, *La Physique de Straton* (1890). (F. Wt.)

**STRATOSPHERE**, the second layer of the atmosphere, above the troposphere and below the mesosphere. Its lower boundary, the tropopause, is located where the tropospheric temperature decrease of about 6° C. per km. is replaced either by a much smaller decrease or, more often, by constant temperature or slight increase with elevation. Approximate heights and temperatures of the tropopause are shown in the table. These figures are averages along the meridian 80° W. but they are representative for other longitudes and for the southern hemisphere. The tropopause is lower at higher latitudes. It is not a continuous

Heights and Temperatures of the Tropopause

Latitude	90° N.	60° N.	30° N.	0°
January . .	8.5 km., -60° C.	9 km., -55° C.	12 km., -55° C. 17 km., -70° C.	18 km., -80° C.
July . . . .	9 km., -45° C.	10 km., -50° C.	16 km., -70° C.	16 km., -73° C.

surface between the poles and the equator. The polar tropopause extends to about 30° lat. in winter and 35° lat. in summer, while the tropical tropopause can be followed as far as 45° lat. There is thus a multiple tropopause at middle latitudes (indicated by the two values for 30° N. in the table). The polar tropopause is lowest in winter, the tropical tropopause in summer. The temperature in the stratosphere is generally highest in summer, ex-

cept for one region at about 45° lat. between 14 and 18 km. where the temperature is about 2° C. higher in January than in July. The greatest seasonal warming in the stratosphere occurs at high latitudes because of the length of polar summer days.

The latitudinal temperature variation is smaller in the stratosphere than in the troposphere. At 20 km. elevation, for instance, the January temperature increases from about -70° C. at the equator to -55° C. or higher around 55° N. and then decreases to -75° C. at the north pole. In July, at the same height, the temperature rises continuously from -60° C. at the equator to -40° C. at the north pole. Above approximately 30 km. the temperature increases again because of the absorption of ultraviolet solar radiation by ozone and reaches a maximum of roughly 0° C. in the vicinity of 50 km. This is the level of the stratopause which separates the stratosphere from the next higher layer, the mesosphere, where the temperature decreases with elevation. Variations in space and time of the stratopause are not well known.

Outstanding features of the stratospheric winds in the northern hemisphere at 80° W. are: during January, a strong westerly jet with a maximum of 100 knots centred at the tropopause at 40° lat.; another strong west wind maximum, 80 knots, at 70° lat. and 25 km. altitude; and an easterly current with a maximum of 40 knots at 20° lat. and about 25 km. During the month of July the mid-latitude jet at the tropopause has a velocity maximum of only 50 knots, and the higher stratosphere has easterly currents at all latitudes.

The air density at 10 km. is about 30% of the sea level value, at 30 km. only slightly more than 1%. But the composition of the air, especially the relative proportion of the two main constituents, molecular oxygen and nitrogen, is the same as in the troposphere, indicating considerable vertical mixing. Ozone (q.v.) is more abundant than below. The water-vapour density is quite low because of the low temperature, and saturation seems to occur only rarely. Between 20 and 30 km. one occasionally observes clouds which are called mother-of-pearl or nacreous clouds because of their characteristic colouring.

The stratosphere is under more radiational control than the troposphere, where horizontal and vertical motions are of greater importance. The characteristic stratospheric temperature distribution is due mainly to the interaction of solar and terrestrial radiation. But strong atmospheric disturbances extend well up into the stratosphere and produce day-to-day changes there just as in the troposphere.

See also ATMOSPHERE; GEOCHEMISTRY: *Geochemistry of the Atmosphere*, and references under "Stratosphere" in the Index. (B. Hz.)

**STRAUBING**, a town of West Germany in the *Land* (state) of Bavaria, Federal Republic of Germany, lies on the Danube, 23 mi. (37 km.) SE of Regensburg on the rail route to Passau. Pop. (1961) 36,348. There were Neolithic settlements there, and the Celtic community on the site was taken over by the Romans and called Sorviodurum. In about 800 Straubing came into the possession of the cathedral chapter of Augsburg, which in 1180 built St. Peter's Church. The new town was founded west of the old in 1218; a tower (1316) marks its centre. Other churches include St. James's (15th century), and the Church of the Carmelites (1430). The main industries are brewing, electrical engineering, and the manufacture of tiles, and of clothing and hats. (I. Ro.)

**STRAUS**, a family of U.S. merchants, industrialists, and diplomats. LAZARUS STRAUS emigrated to the United States from Rhenish Bavaria in 1852. Two years later he was joined by his wife and four children. Lazarus and his son ISIDOR (1845-1912) formed the partnership of L. Straus and Son, which took over the pottery and glassware department of the R. H. Macy and Company department store in New York City. Two sons, NATHAN (1848-1931) and OSCAR SOLOMON (1850-1926), joined the firm in 1881. In 1888 Isidor and Nathan became partners in Macy's and in 1896 became its sole owners. Under their direction Macy's developed into one of the world's largest department stores. Isidor and Nathan also established a Brooklyn department store, Abraham and Straus. Isidor served a short term in the U.S. Congress as a result of a special election in 1893. Both Isidor and

Nathan had many philanthropic interests, Nathan being very active in public welfare work with a particular interest in child health. Isidor and his wife died in the sinking of the "Titanic" in 1912. Nathan's son NATHAN STRAUS (1889-1961) was active in public affairs and served as administrator of the U.S. Housing Authority (1937-42).

OSCAR SOLOMON STRAUS (1850-1926), although he spent some years in the family business, was primarily a lawyer, diplomat, and author. He graduated from Columbia Law School in 1873. From 1887 to 1889 and again from 1898 to 1900 he was U.S. minister to Turkey. He served as secretary of commerce and labour under Pres. Theodore Roosevelt. In 1909 he returned to Turkey as the first U.S. ambassador to the Ottoman Empire. He was appointed chairman of the New York Public Service Commission in 1915. He published several books on U.S. history and in 1922 published an autobiographical work, *Under Four Administrations: From Taft to Cleveland*.

JESSE ISIDOR STRAUS (1872-1936), son of Isidor, became an executive of Abraham and Straus, and from 1919 to 1933 served as president of Macy's. During the last few years of his life he was U.S. ambassador to France. PERCY SELDEN STRAUS (1876-1944), brother of Jesse Isidor, assumed the presidency of Macy's in 1933 and served in that capacity until 1940 when he became chairman of the board. In 1940 JACK ISIDOR STRAUS (1900- ), the grandson of one of the two Straus family members who were first partners in the Macy firm, and son of Jesse Isidor, became president, serving until 1956 when he became chairman of the board. Several other Straus family members served as vice-presidents of Macy's.

ROGER WILLIAMS STRAUS (1891-1957), son of Oscar Solomon, departed from the family business just as his father had before him. After graduating from Princeton in 1913 he joined the American Smelting and Refining Company. After holding various other positions with the company he became president in 1941 and chairman of the board in 1947. (H. J. Sc.)

**STRAUSS**, Austrian family of musicians who achieved wide popularity throughout Europe in the 19th and 20th centuries as composers of waltzes, light music, and operettas in the Viennese style. Other 19th-century musicians bearing the name but having no direct connection with this family are Oscar Straus (1870-1954), composer of the operetta *Der tapfere Soldat*, based on G. B. Shaw's *Arms and the Man* (Vienna, 1908; given in New York as *The Chocolate Soldier*, 1909); Franz Strauss (1822-1905), horn player and composer of music for the horn; and the most prominent musician bearing this name, Franz's son Richard Strauss (q.v.).

JOHANN STRAUSS the Elder (1804-1849) was one of the principal composers of Viennese waltzes. Born in Vienna on March 14, 1804, he became a viola player in the dance orchestra of Michael Pamer, a composer of light music. Later he conducted the orchestra of Josef Lanner and in 1826 performed at the gardens of the "Zwei Tauben" the *Täuberlwalzer*, the first of many sets of Viennese waltzes named after the places where they were heard. In 1824 he married Anna Streim, the daughter of an innkeeper. He established his reputation as a composer of Viennese waltzes in 1830 by conducting at the "Sperl," a popular dance hall in the Leopoldstadt. There he was idolized to the extent of becoming known in the musical world as "the Austrian Napoleon." In 1834 he was appointed bandmaster to the 1st Vienna militia regiment and the following year was made director of the imperial court balls. He embarked in 1833 on the first of his many tours throughout Europe, visiting London in 1838. He died in Vienna on Sept. 25, 1849.

Strauss's complete works, including—besides waltzes—galops, polkas, quadrilles, and other dances, were published by his son Johann in 1889. Remarkable for their rhythmic verve and charm of melodic design, they represent the style of Viennese dance music at its best.

JOHANN STRAUSS the Younger (1825-1899), son of the above, developed the style of the Viennese waltz and became known for his operettas. Born in Vienna on Oct. 25, 1825, he started his career as a bank clerk, since his father wished him to follow a

THE GRANGER COLLECTION

PHOTOGRAPHED ABOUT 1872

profession other than music. He studied the violin without his father's knowledge, however, and in 1844 conducted a dance band formed by himself at a Viennese restaurant. In 1849, when the elder Strauss died, Johann combined his orchestra with his father's and with it traveled all over Europe, including Russia (1865-66), and England (1869), winning great popularity. In 1872 he visited the United States and conducted concerts in New York and Boston. Earlier he had married Henrietta (Jetty) Treffz, a popular singer, and in the same year relinquished leadership of his orchestra to his brothers, Josef and Eduard, to spend his time writing music.

Strauss's most famous single composition is "An der schönen blauen Donau" ("The Blue Danube"; 1867), the main theme of which became one of the best-known tunes in 19th-century music. His many other melodious and successful waltzes include "Morgenblätter" (1864), "Künstlerleben" (1867), "Geschichten aus dem Wienerwald" (1868), "Wein, Weib und Gesang" (1869), "Wiener Blut" (1871), and "Kaiserwalzer" (1888). His waltzes number over 150, their popularity, which is still maintained, earning him the name "the Waltz King." Like his father he also wrote dances of several other kinds. Among his stage works, *Die Fledermaus* (1874) became the classical example of Viennese operetta. Other successful operettas were *Der Carneval in Rom* (1873), *Cagliostro in Wien* (1875), *Das Spitzentuch der Königin* (1880), *Der lustige Krieg* (1881), *Eine Nacht in Venedig* (1883), *Der Zigeunerbaron* (1885), and *Waldmeister* (1895). He died in Vienna, June 3, 1899. His second wife, Angelica, who long survived him, published his letters in 1926.

JOSEF STRAUSS (1827-1870), born in Vienna on Aug. 22, 1827, was the brother of Johann Strauss the younger. He was a composer and conductor of waltzes, among them *Dynamiden*, used by Richard Strauss for a theme in *Der Rosenkavalier*. He died in Vienna on July 21, 1870.

EDUARD STRAUSS (1835-1916), born in Vienna on March 15, 1835, was also a brother of Johann Strauss the younger. He deputized for his more famous brother during Johann's visit to Russia and succeeded him in 1870 as conductor of the imperial court balls. He died in Vienna on Dec. 28, 1916.

JOHANN STRAUSS (1866-1939), born in Vienna on Feb. 16, 1866, the son of Eduard Strauss, became known as a conductor of light music. He died in Berlin on Jan. 9, 1939.

**STRAUSS, DAVID FRIEDRICH** (1808-1874), German theologian and biographer, author of one of the most sensational books on religion of the 19th century, the *Leben Jesu*, which first brought to wide public attention the new trends in biblical exegesis. He was born at Ludwigsburg, near Stuttgart, on Jan. 27, 1808, and studied at the University of Tübingen. After a short interval of teaching he went to Berlin (1831), where he was influenced by F. D. E. Schleiermacher and Hegel's followers. On his return to Tübingen he lectured for a time but soon found it necessary to give his whole energies to the preparation of the *Leben Jesu*. The work, published in 1835-36 (English translation, *Life of Jesus*, three volumes, 1846), produced an immense sensation since it applied the myth theory to the life of Jesus, denied the historicity of all supernatural elements in the Gospels, and interpreted the growth of primitive Christianity in Hegelian terms. In 1840-41 he published *Die christliche Glaubenslehre* (two volumes), the principle of which is that the history of Christian doctrines is their disintegration.

Strauss had been elected to a chair of theology in the University of Zürich, but so great was the hostility aroused by his *Leben Jesu* that the authorities pensioned him off before he was installed. With his *Glaubenslehre*, Strauss abandoned theology for 20 years, publishing during the period a series of biographical works that secured a permanent place for him in German literature. In 1864, however, he returned to theology with his *Leben Jesu für das deutsche Volk*. His *Der Christus des Glaubens und der Jesus der Geschichte* (1865) is a severe criticism of Schleiermacher's lectures on the life of Jesus. From 1865 to 1872 Strauss resided in Darmstadt, and in 1870 published his lectures on Voltaire. His last work, *Der alte und der neue Glaube* (1872; Eng. trans., *The Old Faith and the New*, 1873), caused some consternation among his friends; essentially it rejects Christianity in favour of scientific materialism, and like all his critical works it suffered from his lack of critical study of the texts. Strauss died on Feb. 8, 1874.

Strauss's works were published in a collected edition in 12 volumes by E. Zeller (1876–78) without his *Christliche Dogmatik*. His *Ausgewählte Briefe* appeared in 1895.

**BIBLIOGRAPHY.**—E. Zeller, *David Friedrich Strauss in seinem Leben und seinen Schriften* (1874; Eng. trans., 1874); A. Hausrath, *D. F. Strauss und die Theologie seiner Zeit*, 2 vol. (1876–78); S. Eck, *D. F. Strauss* (1899); K. Harraeus, *D. F. Strauss, sein Leben und seine Schriften* (1901); T. Ziegler, *D. F. Strauss*, 2 vol. (1908–09); Albert Schweitzer, *The Quest of the Historical Jesus*, Eng. trans., pp. 68–120 (1910).

**STRAUSS, RICHARD GEORG** (1864–1949), German composer of orchestral works and operas illustrating the aesthetic of the Romantic movement at its final and farthest point of development, was born in Munich on June 11, 1864. His mother belonged to the Pschorr brewing family in Munich, and his father, Franz Joseph Strauss (1822–1905), was principal horn in the court orchestra there and the finest horn soloist in Germany. Strauss had his first piano lessons when he was four, and wrote his first composition, a Christmas carol, when he was six. He studied the violin from 1871 onward, and musical theory from 1875, but his formal education was a normal academic one, carried to university level with the study of philosophy, history, and aesthetics. He wrote music abundantly throughout his school years; the earliest of his works to be acknowledged was the orchestral *Festmarsch*, op. 1 (performed 1876). By 1880 his works were being performed in public, and before he graduated from Munich University a group of eight songs, op. 10, was published which include three—"Zueignung," "Die Nacht," "Allerseelen"—that were still favourites 80 years later.

After graduation Strauss spent some time in Berlin where he met Hans von Bülow. Having conducted Strauss's Wind Serenade, op. 7, Bülow asked him to compose a longer suite for the woodwind of the Meiningen Court Orchestra. This was included in the repertory of a tour by the orchestra, and Bülow invited Strauss to conduct the première of the work in Munich on Nov. 18, 1884.

As a result of this debut, Bülow obtained for Strauss the post of assistant conductor at Meiningen. Here were laid the foundations of Strauss's secondary career, as an outstanding conductor, and at Meiningen, too, he was converted as a composer to the forward-looking ideals of Liszt and Wagner. When his stay at Meiningen ended in 1886 Strauss was appointed third conductor at the Munich Opera; his subordinate status irked him, but during this time he composed the symphonic poems *Aus Italien*, *Macbeth* (first version), and *Don Juan*, and began his first opera *Guntram*. He also met the singer Pauline de Ahna, whom he later married and with whom he often gave song recitals.

THE BETTMANN ARCHIVE  
RICHARD STRAUSS, PHOTOGRAPHED  
IN 1949

From 1889 to 1894 he held the directorship of the Weimar Court Orchestra; the great success of *Don Juan* in 1889 was followed by *Tod und Verklärung* (1890), a revised *Macbeth* (1890), and, less successful, the Wagnerian *Guntram* (Weimar, 1894). Strauss then returned to a more senior post in Munich. The brilliant, uproarious *Till Eulenspiegel* (1895), *Also sprach Zarathustra* (1896), based on Nietzsche, and *Don Quixote* (1898), the finest and most elaborate of all these tone-poems, were all produced during this period. Strauss was now frustrated in Munich, and the fiasco of *Guntram* there turned him against his native city. As a result he wrote the satirical comic opera *Feuersnot* on a libretto by Ernst von Wolzogen, mocking small-town prudery and hypocrisy; its première (1901) was the first of many of his works introduced at Dresden. Fortunately Strauss, at the climax of his disenchantment with Munich, was appointed first conductor of the Prussian Royal Orchestra, and in 1898 moved to Berlin. There he spent fruitful years conducting concerts and opera, completing the autobiographical tone poems *Ein Heldenleben* (1899) and *Symphonia Domestica* (1904; a New York première during Strauss's tour of the U.S.), undertaking guest appearances in Germany and abroad, and establishing himself as Germany's foremost composer. The orchestral symphonic poems, completed with the *Alpine Symphony* (1915), proclaim an extraordinary mastery of the big post-Romantic symphony orchestra, an unrivaled descriptive power, and a remarkable ability to convey psychological detail in music. This last quality was particularly developed in his operas from *Salome* (Dresden, 1905; on the play by Oscar Wilde) onward.

**Collaboration with Hofmannsthal.**—*Elektra* (composed 1906–08) marked the beginning of a collaboration with Hugo von Hofmannsthal, which lasted until the poet's death in 1929, and produced many of Strauss's finest works. *Der Rosenkavalier* (Dresden, 1911), the second of their joint works, was the most successful of all Strauss's operas. *Ariadne auf Naxos*, at first designed to include a German adaptation of Molière's play *Le Bourgeois gentilhomme*, was produced in this form by Max Reinhardt (Stuttgart, 1912), and later revised as a self-sufficient opera with an explanatory prologue (Vienna, 1916). *Die Frau ohne Schatten* (Vienna, 1919), a symbolic fantasy on the relationship between the individual and society, is sometimes held to be their greatest joint work. *Die ägyptische Helena* (Dresden, 1928) is a fanciful drama on the subject of Menelaus and Helen on their return journey from Troy. Finally *Arabella* (Dresden, 1933), a Romantic comedy, was set in the Vienna of 1860. The libretto was completed shortly before Hofmannsthal's sudden death.

In 1908 Strauss settled at Garmisch-Partenkirchen in the Bavarian Alps, and was able to devote most of his time to composition. His other major works during the period of collaboration with Hofmannsthal are the ballet *Josephslegende* (scenario by Hofmannsthal and H. Kessler; Paris, 1914) for Diaghilev's Ballets Russes (Paris, 1914), the autobiographical comic opera *Intermezzo*, to his own libretto (Dresden, 1924), the entertaining ballet *Schlagobers* (Vienna, 1924), and a performing version of Mozart's *Idomeneo* (Vienna, 1930). In 1919 he accepted the post of musical director to the Vienna Opera, in collaboration with Franz Schalk, which he held until 1924, when difficulties caused by his frequent tours abroad forced his resignation. In recognition of his 60th birthday he was granted the freedom of the cities of Vienna and Munich, and given a villa in Vienna.

**Final Period.**—Hofmannsthal's death left Strauss in search of a librettist. Stefan Zweig provided him with an adaptation of Ben Jonson's *Epicoene*, produced at Dresden as *Die schweigsame Frau* (1935). But in Nazi Germany Zweig, a Jew, was unacceptable, and despite Strauss's protests of loyalty Zweig retired in favour of Joseph Gregor, who wrote (with much assistance from Zweig, and later from Clemens Krauss and others) the texts of three operas, *Friedenstag* (Munich, 1938), *Daphne* (Dresden, 1938), and *Die Liebe der Danae* (Salzburg, 1952). Strauss's position in Nazi Germany was ambivalent. He lacked political affiliations and interests to a point of naïveté. He disliked the philistine characteristics of Nazi officials, and made himself unpopular by his objections to government interference in artistic matters, especially when these concerned his own music.

Not wishing to leave home, he accepted Hitler's regime more or less passively. He served as president of the state music council (1933–35) and replaced Toscanini and Bruno Walter as conductor when they refused to work in Nazi Germany. After completing *Die Liebe der Danae* in 1940 he intended to retire from composition. But he wrote one more opera, *Capriccio* (Munich, 1942), based on an elegant Romantic discussion on the relationship between words and music in opera, the protagonists being Parisian characters of the period of Gluck. He himself wrote the libretto with Krauss and others. During his last years he found creative energy to return to orchestral music and to compose a series of cool, neoclassical works: a second horn concerto (1943), two works for wind band (1944, 1945), the sombre, meditative *Metamorphosen* for 23 solo strings (1946), the Oboe Concerto (1946), and Duet Concertino for clarinet and bassoon with strings (1948). His life's work was completed with the richly scored, poignantly retrospective *Vier letzte Lieder* ("Four Last Songs"; 1950) for soprano and orchestra.

During World War II Strauss had lived at home at Garmisch. After the war he lived in Switzerland. His health deteriorated but he was able to attend a Strauss festival in London in 1947. He returned to Germany for his 85th birthday celebrations, and in July 1949 he conducted an orchestra for the last time. After a heart attack, he died at Garmisch-Partenkirchen on Sept. 8, 1949.

Strauss was reared on the musical classics and on the early romantic composers up to the period of Schumann; so much may be gathered from his youthful works including the F minor symphony, op. 12, and the Violin Concerto, op. 8, the Horn Concerto no. 1, and the Violin Sonata, op. 18. He came under the influence of Berlioz, Liszt, and Wagner just when his technique and imagination were sharpened to make the most of their impact. From *Aus Italien* onward his style becomes recognizable as the big, bravura, flexible, post-Romantic panoply that dominated audiences and influenced composers as different as Bartók and Szymanowski. In *Elektra* Strauss occasionally broke the bounds of tonality, but this was to achieve special effects and not to establish a nontonal technique.

In *Der Rosenkavalier*, reflecting the outlook and the temper of 18th-century Vienna, Strauss regained his authentic manner. Thereafter he spent 38 years refining and polishing his style, writing often for small orchestras, partly out of practical considerations (to ensure, for instance, the audibility of sung words in the theatre), partly because large-scale Romantic textures were becoming less and less significant. In later years Strauss's style became more classical, in the Mozartian sense. In *Capriccio*, *Metamorphosen*, and the *Four Last Songs* he may be said to have achieved a perfect fusion of the Romantic German and the neoclassical manner. After *Elektra* his evolution as a composer was pursued in isolation and was hardly influenced by the course of music outside his own country.

**STRAVINSKY, IGOR FEDOROVICH** (1882– ), Russian-born composer, one of the most original, fertile, and influential figures in 20th-century music, was born at Oranienbaum, near St. Petersburg (now Leningrad), June 17 (N.S.; 5, O.S.), 1882. His father, Fedor (d. 1902), was a well-known operatic bass singer. Although Igor was not intended for a musical career, as a boy he was taught to play the piano and he frequented the opera and ballet performances at the Maryinsky Theatre. As a university student he read law but showed no special aptitude for his studies, having apparently made up his mind to devote himself to composition. When he was about 20 he consulted Rimski-Korsakov, who advised him not to enter an academy and agreed to give him private tuition himself.

For some years Stravinsky lived in St. Petersburg, where he married Catherine Nossenko in 1906; but the great success of *The Firebird*, his first commission for the Russian Ballet, led him to

THE BETTMANN ARCHIVE

IGOR STRAVINSKY, INK DRAWING BY PICAASSO, 1920

take his family to western Europe in 1910. The outbreak of World War I caught them in Switzerland; and the Russian Revolution of 1917 not only cut him off from his Russian property, but turned his temporary exile into a permanent one.

After the war he settled in France, becoming a French citizen in 1934. In 1939 his wife and mother died; and shortly after the outbreak of World War II he left France for the United States. In 1940 he married Vera de Bosset and settled in Hollywood; five years later he became a U.S. citizen. The disruptions of a long life, with two changes of nationality, are reflected in

the quantity and varied style of his compositions.

Stravinsky's apprentice works, written under the supervision of Rimski-Korsakov, included a Symphony in E♭ (1905–07) and groups of songs. Shortly after Rimski-Korsakov's death in 1908 Stravinsky's *Scherzo Fantastique* and *Fireworks* were heard at an orchestral concert by Sergei Diaghilev, who was so favourably impressed that he asked him to write a ballet score for the 1910 season of the Russian Ballet. This was *The Firebird* (first performance, Paris, 1910), in which Stravinsky showed how fully he had assimilated the romantic idiom and orchestral palette of his master.

The success of *The Firebird* was so complete that he became known overnight as one of the most gifted of the younger composers, and Diaghilev was anxious to secure his continued cooperation. *Petrouchka* followed in 1911. The first performance of *The Rite of Spring* (Paris, May 29, 1913) caused a near-riot in the Théâtre des Champs-Élysées, but this, in the long run, did much to consolidate Stravinsky's growing reputation. The following year Diaghilev's company produced his first opera, *The Nightingale*, in Paris and London. The vocal score of *The Wedding*, a dance cantata based on Russian peasant wedding customs, was written during 1914–17, though it took another six years to discover the right instrumental formula.

World War I seriously disrupted the Russian Ballet's activities, and Stravinsky could no longer rely on it as a regular outlet for his new compositions. During these years of enforced exile he concentrated on chamber music of various kinds and produced two strikingly original stage works, *Reynard* (1915–16) and *The Soldier's Tale* (1918).

The compositions of his first maturity—from *The Rite of Spring* to the *Symphonies of Wind Instruments* (1920)—make use of a modal idiom based on Russian sources and are characterized by a highly sophisticated feeling for irregular metres and syncopation and by brilliant orchestral mastery. His postwar decision not to return to Russia led to a break in style. Diaghilev's request that he should adapt some music by Pergolesi for a commedia dell'arte ballet, *Pulcinella* (1919–20), helped him to review his attitude to the main European musical tradition, and the result was a series of works which seemed to be dominated by neoclassical procedures. At the same time financial necessity forced him to develop a subsidiary career as pianist and conductor. The Concerto for piano and wind instruments (1923–24), *Capriccio* for solo piano and orchestra (1929), and the Concerto for two solo pianos (1934–35) were written to suit his ability as a solo pianist. The Violin Concerto (1931) was commissioned for Samuel Dushkin, the U.S. violinist, and Stravinsky conducted many performances of the work. Several ballet scores were written during this period: *Apollo Musagetes* (1928), the last ballet of his to be mounted by Diaghilev; *The Fairy's Kiss* (1928), after music by Tchaikovsky, and *Persephone* (1933–34), both commissioned by Ida Rubinstein for her ballet company; and *The Card Party* (1936), for the American Ballet. The two peaks of

this early neoclassical period are the opera *Oedipus Rex* (1926-27), on a Latin libretto, and the *Symphony of Psalms* (1930) on extracts from the Vulgate.

The appearance of two important symphonies coincided with the beginning and end of World War II: the *Symphony in C* (1938-40) and the *Symphony in Three Movements* (1942-45). To the immediate postwar years belong the ballet *Orpheus* (1947), written for the Ballet Society of New York; the *Mass* (1944-48), and his only full-length opera, *The Rake's Progress* (1948-51), on a libretto by W. H. Auden.

Although the success of these works was not in dispute, Stravinsky seemed to feel that he had outgrown the particular neoclassical conventions in which he had been working for 30 years. He had recently met Robert Craft, a young conductor in New York; later he invited him to Hollywood, and in time Craft became invaluable to him as a musical assistant. Stravinsky welcomed the opportunity, afforded by Craft's interest in serial music, to familiarize himself with the compositions of Anton Webern and Arnold Schoenberg, and he became so interested in serialism that he gradually adopted it for his own purposes. (See DODECAPHONY.) His earliest serial essays, such as *In Memoriam Dylan Thomas* (1954), *Canticum Sacrum* (1955), and the ballet *Agon* (1953-57), all retained some kind of tonal framework: only with *Threni* (1957-58) and *Movements* (1958-59) did he become the complete serialist. The most ambitious work of this period is *The Flood* (1961-62); but this was written for television and makes a somewhat diffuse and patchy effect in the theatre or concert hall. More concentrated and more moving are the *Requiem Canticles* (1965-66), where each of the brief nine movements is carefully characterized and sharply differentiated.

Critics and the public have frequently been disconcerted by Stravinsky's various changes of style; but in the course of time, many idiosyncrasies that proved upsetting at a first hearing have fallen into proper perspective.

Stravinsky's literary works include an autobiography covering the first 52 years of his life, *Chronicle of My Life* (anon. Eng. trans., 1936); *Poetics of Music* (Eng. trans. by A. Knodel and I. Dahl, 1947); and five books in collaboration with Robert Craft: *Conversations* (1959), *Memories and Commentaries* (1960), *Expositions and Developments* (1962), *Dialogues and a Diary* (1963), and *Themes and Episodes* (1966).

See R. Vlad, *Stravinsky* (Eng. trans. by F. and A. Fuller 1960); Eric Walter White, *Stravinsky: the Composer and His Works* (1966). (E. W. WH.)

**STRAW**, the stalks of grasses, particularly of such cereal grasses as wheat, oats, rye, barley, and buckwheat. Used collectively, the term denotes such stalks in the aggregate after drying and threshing of the grain.

From ancient times man has used straw as litter and fodder for cattle, covering for floors, his own coarse bedding, and even clothing for his body. The thatched roof, still not without usefulness in some parts of the world, consists of straw laid down to a thickness of a foot or more and secured by strong cords, with the fibres running in the direction to be taken by rainwater.

Straw has its finer uses also, one of which is hat making. For this purpose cereals are specially grown and carefully selected for fine colour, lightness of weight, and toughness. Dunstable wheat straw provides an excellent plait that has long been important in English straw-hat manufacture. The middle part of the straw above the last joint is chosen and cut into ten-inch lengths that are split by machine into strips of required widths. One form of Dunstable plait is composed of 7 whole straws, while another consists of 14 split straws. Straw hats are also produced in the Orient. A justly famous hat-making plait is leghorn. A product of Tuscany in Italy, it is obtained from a special variety of wheat, *Triticum aestivum*, which is thickly sown and harvested before the grain is entirely ripe. The stalks are dried and sun bleached, and the upper part of the stalk down to the first joint is selected for making plaits. A finer, lighter, pearly-white straw is obtained from the lower part of the stalk from which the sheath is removed. Panama hats are not made from straw, but from the fibre of the toquilla leaf.

Straw, either in natural colouring or dyed in attractive hues, may be woven into matting for floor and furniture covering. Woven straw is also sometimes employed as a protective covering for fragile objects. One of the oldest and most attractive uses of straw is in basket making.

Chemically pulped straw is utilized in the manufacture of a coarse paper and a cardboard (strawboard) suited to the production of cheap paper boxes. Straw has also been used to fabricate adobe walls, where sun-baked brick made of clay is moistened and kneaded and combined with chopped straw. (E. L. Y.)

**STRAWBERRY**, well-known fruit plant with red fragrant, edible "fruit" (see below), of eight main species of the genus *Fragaria*, native to the temperate regions of the Northern Hemisphere and extending to Patagonia in the New World. In North America the meadow strawberry (*F. virginiana*) is native to the East and the beach strawberry (*F. chiloensis*) is found on the Pacific coast from Alaska down to the Andes of southern Chile. The woodland strawberry (*F. vesca*) is native to North and South America and Asia, where other species are found. In Europe the woodland strawberry is widely distributed, with the alpine strawberry (*F. vesca semperflorens*) being found at higher altitudes; there are two other less common species. All are very small fruited with fragrant but pippy berries.

JOHN MARKHAM  
WOODLAND STRAWBERRY (*FRAGARIA VESCA*) IN FLOWER

**Plant Characteristics.**—The strawberry is a low-growing, herbaceous plant with a fibrous root system and a crown from which arise basal leaves. The leaves are compound, with three leaflets, sawtooth edged and hairy. The flowers, generally white, rarely reddish, are borne in small clusters on slender stalks that arise, like the surface-creeping stems (runners or stolons), from the axils of the leaves. As a plant ages, the root system becomes woody and the "mother" crown sends out runners that touch ground and root, thus enlarging the plant. Runner plants, removed and planted when their root system is sufficiently developed, are used to propagate named varieties.

**The Fruit and Its Composition.**—The strawberry fruit in the botanical sense is not a berry and is much more than a single fruit: it is the greatly enlarged stem end or receptacle, in which are partially embedded the many true fruits, or achenes (popularly called seeds). The achenes are dried ovaries containing the seeds.

Strawberries are 90% water by weight. One cupful of them yields 90 calories. They have more vitamin C than an equal quantity of lemons—a handful of fresh-picked strawberries supplies an adult man's entire day's need of vitamin C—and more vitamin A than the same weight of raisins.

**Cultivated Varieties.**—The cultivated, large-fruited strawberry originated in Europe in the 18th century. The woodland strawberry had long been cultivated in England, France, and Italy but no improvement in size and succulence occurred until species were introduced from the New World. Crosses of *F. chiloensis* and *F. virginiana* with *F. vesca* resulted in large-fruited types, an early one of which was the celebrated Ananassa strawberry raised in France probably from *F. virginiana* × *F. chiloensis*.

Most countries have their own varieties raised during the 19th century and often particularly suitable for the climate, day length, altitude, or type of production required. In Europe varieties are introduced from the horticultural institutes in England, Scotland, France, Germany, Holland, and elsewhere, and also by commercial firms. In the United States the Department of Agriculture frequently introduces new varieties, and in most states where the strawberry is an important crop some breeding work is undertaken. Field resistance to red core (red stele), a fungus disease, is an important advantage of some of the newer

varieties, such as Stelemaster and Surecrop in the United States and Redgauntlet and Cambridge Vigor in Europe.

**Cultivation.**—The strawberry succeeds on a surprisingly wide range of soils and situations and, compared with other horticultural crops, has a low fertilizer requirement. Since it is susceptible to drought, it requires moisture-retaining soil or irrigation by furrow or sprinkler. Runner plants are planted in early autumn if a crop is required the next year. If planted in winter or spring, the plants are deblossomed to avoid a weakening crop the first year. Plants are usually retained for one to four years. Runners may be removed from the spaced plants, or a certain number may be allowed to form a matted row alongside the original parent plants. The spaced plants per acre varies from 7,000 to as many as 17,000.

In areas of north Europe and North America where severe winters are experienced, plants are put out in the spring and the established plantation protected during following winters by covering the rows with straw or mulches. Weeds, which have always been a problem in strawberry plantations, formerly required much hand labour. However, since World War II, herbicides (simazine, 2,4-D, chloroxuron) have been developed to control annual weeds. Chemicals can also be used for killing unwanted runner plants. The chief pathogens are root diseases, fruit rots, leaf blotches and mildews, virus diseases, and infestations from nematodes, leaf hoppers, and aphids.

The initiation of flowers and the production of runners is determined mainly by day length, probably through complex hormonal balance, but there are marked varietal differences. Most varieties produce flowers only in the spring and the fruit ripens about five weeks later. Some varieties produce further flowers and another crop later in the summer. True perpetual, everbearing, or remontant varieties produce flowers and fruit continuously from spring until frost, both on the parent plant and the runners of the same year. These varieties—including Progressive and Mastodon—are suitable for home cultivation.

Commercial production of strawberries is for immediate consumption, and for processing as frozen, canned, or preserved berries or as juice. In all countries, because of the perishable nature of the berries and the unlikelihood of mechanical picking, the strawberry is generally grown near centres of consumption or processing, and where sufficient labour is available. The berries are picked direct into small baskets, crated for market, or into trays for processing. Early crops can be produced under glass or plastic covering. Strawberries are very perishable and require cool (though not refrigerated), dry storage.

**Production.**—The United States produces over 250,000 metric tons annually, approximately equal to the entire production of western Europe. Winter and spring crops come from Florida and the Gulf and southeastern states. The main bulk of crops are grown in California with irrigation, but production is widespread near most consuming centres. Strawberries are grown in all European states, France, Italy, and the United Kingdom being the major producers. Production in Italy increased markedly after World War II mainly in the irrigated Po Valley. In England main production areas are in the southern and eastern counties, and in France in the Rhone Valley, in Brittany, and elsewhere. Bulgaria and Poland have increased production, mainly for export as processed pulp. There is a small production in southern and eastern Africa, where altitude provides sufficient winter chilling, in New Zealand, and in Victoria and New South Wales in Australia. Japan has increased production because of labour availability.

CULTIVATED VARIETY OF STRAWBERRY

See Ministry of Agriculture [U.K.] *Bulletin 95, Strawberries* (1962); U.S. Department of Agriculture, *Farmers' Bulletins*, South Atlantic and Gulf Coast, No. 1026 (1958), Eastern United States, No. 1028 (1961). (H. M. H.)

**STREATHAM**, a residential and shopping district in Wandsworth, London, Eng. Streatham Common (67.75 ac.) rises to about 250 ft. (76 m.); there are several sports grounds in the area. Streatham Place, a house on the south side of Tooting Bec Common, pulled down in 1863, belonged to the brewer Henry Thrale (d. 1781). For many years Dr. Johnson (see JOHNSON, SAMUEL) spent long periods there; other notable visitors included Boswell, Fanny Burney, David Garrick, Sir Joshua Reynolds, and Edmund Burke.

**STREET, GEORGE EDMUND** (1824–1881), English architect noted for his many Gothic churches, was born at Woodford in Essex on June 20, 1824. He worked for five years with the architect Sir George Gilbert Scott in London and in 1849 began his own practice. In 1855 he published *The Brick and Marble Architecture of Northern Italy*, and in 1865 *The Gothic Architecture of Spain*, with beautiful drawings of his own.

Street's personal taste led him in most cases to select for his design the 13th-century Gothic of England or France. The majority of his buildings were for ecclesiastical uses, the chief being the convent of East Grinstead, the theological college at Cuddesden, and a large number of churches, such as St. Philip and St. James's at Oxford, St. John's at Torquay, All Saints' at Clifton, St. Saviour's at Eastbourne, St. Margaret's at Liverpool, and St. Mary Magdalene, Paddington. His largest works were the nave of Bristol Cathedral, the choir of the cathedral of Christ Church in Dublin, and the new courts of justice in London (not completed at the time of his death, on Dec. 18, 1881). Street was a friend of many of the pre-Raphaelite artists; he maintained an interest in various high church organizations within the Church of England and was diocesan architect to Oxford, York, Winchester, and Ripon. He was professor of architecture at the Royal Academy, where he lectured on medieval architecture, and in 1881 he was elected president of the Royal Institute of British Architects. He was buried in the nave of Westminster Abbey.

**STREETCAR:** see ELECTRIC TRACTION.

**STREETER, BURNETT HILLMAN** (1874–1937), English theologian and biblical scholar, best remembered for his original contributions to knowledge of Gospel origins, was born Nov. 17, 1874, at Croydon. Most of his life was spent at Queen's College, Oxford, where he became chaplain in 1928 and provost in 1933. He was ordained in 1899, and for 15 years—from 1922 to 1937—was a member of the Archbishop's Commission on Doctrine in the Church of England. He wrote or contributed to a dozen volumes in the fields of philosophy of religion, comparative religion, and New Testament studies.

While Streeter regarded his work as primarily philosophical—the contemporary interpretation of religion—he is more widely known as a student of the New Testament. He contributed an important essay to the *Oxford Studies in the Synoptic Problem* (1911), but his most important work was *The Four Gospels: A Study of Origins* (1924). In this he originated a "four document hypothesis" (including a Proto-Luke) as a solution to the synoptic problem, and developed the theory of "local texts" in the manuscript transmission of the New Testament. (See GOSPELS: THE "Synoptic Problems.") His section on the Caesarean text was very influential in subsequent studies in this field. This work was followed in 1929 by *The Primitive Church*, in which he argued that there were three (not one) systems of church government in the earliest Christian churches.

Streeter followed "the hue and cry after new discovery" into fields as diverse as *Foundations: a Statement of Christian Belief in Terms of Modern Thought*, by Seven Oxford Men (1912), *The Chained Library* (1931), *Reality: a New Correlation of Science and Religion* (1926), and *The Buddha and the Christ* (Bampton Lectures, 1932). He also was an enthusiastic follower of Frank Buchman and the Oxford Group. Streeter and his wife were killed in an airplane crash in Switzerland on Sept. 10, 1937. (E. C. Co.)

**STRELTSY** (plural, from singular *strelets* "musketeer"), a Russian military corps that came into being in the middle of the 16th century and for about 100 years made up the bulk of the Russian Army. By the middle of the 17th century, the *streltsy* had developed into a hereditary military caste. In peacetime the Moscow *streltsy* provided the tsar's bodyguard and performed police and security duties. The municipal *streltsy* had a similar function in the border towns that they garrisoned. In the second half of the 17th century the government adopted a policy of substituting landholdings for the *streltsy's* payment in money and grain, and this was one of the causes of their discontent and consequent unreliability. The poorer *streltsy* more than once sided with the rioters or rebels whom they were supposed to quell. In spite of this, their number grew from about 40,000 in 1632 to 55,000 in 1681; 22,500 of them were stationed in Moscow. The *streltsy* lived in their own settlements (*slobody*) and were organized in regiments administered by the *streletski prikaz* ("office") in Moscow.

In 1682 the revolt of the *streltsy* against the family of Naryshkin (*q.v.*), which had been fomented by the rival family of Miloslavski, was skilfully exploited by the regent Sophia (*q.v.*) Alekseevna and by F. L. Shaklovity, whom Sophia had appointed chief of the *streletski prikaz* after the execution of the unreliable I. A. Khovanski. When in June 1698 the *streltsy* attempted to restore Sophia to power, they were defeated by Tsar Peter I's foreign mercenaries under Gen. Patrick Gordon (*q.v.*), while Peter himself was abroad (see PETER I the Great). Returning to Moscow early in September, Peter dealt ruthlessly with the *streltsy*: in the following six weeks 799 were either broken on the wheel or impaled, while 222 were deported. Though in 1702, in the first period of the Northern War, Peter saw fit to revive the *streltsy*, the Moscow *streltsy* were finally disbanded in 1713. (L. R. LR.)

**STREPSIPTERA**, an order of uncommon, usually minute insects, ordinarily referred to as stylops (after the name of a well-known genus), that are parasitic on other insects, especially wasps, ants, wild bees, and leafhoppers. The order contains six families and approximately 400 described species from various parts of the world. Some authorities regard these insects as constituting a peculiar and highly specialized family of beetles (see BEETLE: *Meloidea*).

They exhibit three principal sorts of parasitism. The basic type occurs in the genus *Mengenilla*, whose members, as larvae, attack young silverfish and later emerge from them as adults. The mature females are wingless, but the males have large, fanlike hindwings (folded at rest); short, clublike forewings; bulging eyes; and comblike antennae.

A more common and advanced type is exemplified by the genus *Stylops*, which parasitizes wild bees of the genus *Andrena*. Active young *Stylops*, bristly and long legged, are picked up from flowers by female *Andrena*, who transport them to their nests. Here, the *Stylops* penetrates the bee larva and becomes a sedentary sac-like endoparasite. If the parasite is a female, it remains permanently in the host, but the head of the parasite protrudes from the bee's abdomen at maturity. The male comes out of the host as a winged adult and must locate and fertilize the female in situ through an opening behind her head. The *Stylops* young develop by the thousands inside the bee and emerge through the opening behind the mother's head. The cycle is completed when the larvae are carried to flowers by the bee. This mode of parasitism is so delicately adjusted that the host lives nearly a full life span; however, its reproductive organs do not develop.

A third type of parasitism is represented by the genus *Myrmecolax*, in which young destined to be males develop within ants, and those that will become females develop in katydids and related forms. In these cases, the females are permanently endoparasitic and may attain a length of nearly 1 in.; males of the same species are a conventional  $\frac{3}{16}$  in. long.

(R. M. Bo.)

**STRESA**, a town of Piedmont, Italy, in Novara Province, 673 ft. (205 m.) above sea level, lies on the west side of Lake Maggiore, 4½ mi. (7 km.) S of Verbania by water. Pop. (1961) 5,169.

It is a health and tourist resort, and is frequently chosen as the site of congresses. A conference between Italy, Great Britain and France on European peace, called in an unsuccessful attempt to deal with Hitler's announcement that Germany would rearm despite the prohibitions contained in the Treaty of Versailles, was held there in 1935. Antonio Rosmini-Serbati, founder of the Institute of Charity, died in Stresa in 1855.

**STRESEMANN, GUSTAV** (1878–1929), German parliamentarian and statesman, chancellor of the *Reich* for a short time in 1923 and subsequently, as foreign minister from 1923 to 1929, the principal restorer of his country's international status after the Treaty of Versailles. He was born in Berlin on May 10, 1878, the son of an innkeeper with a small trade in bottled beer, and was the only one of the family to attend high school. Reading literature and history at Berlin University, he developed a strong interest in Goethe and in Napoleon; but his practical bent soon led him to study economics under Karl Bücher at Leipzig. He graduated

RADIO TIMES HULTON PICTURE LIBRARY  
STRESEMANN

as doctor of philosophy in 1902, with a dissertation on the development of the Berlin bottled-beer trade. A liberal Protestant of the Prussian sort, he grew up to believe in the military, political, spiritual, and moral superiority of Germany. His political idealism showed itself in a sentimental affection for the German Liberals of 1848 (see GERMANY: History) and in a romantically appealing turn of speech. An air of youthful carelessness distinguished his oratory even in later years.

**Political Beginnings.**—Unusually rapid success in commerce gave Stresemann a springboard for entry into politics. As assistant to the executive of the German Chocolatemakers' Union in Dresden (1901–04), he won a reputation as a brilliant organizer and as a clever businessman; and from 1902 to 1911 he was legal adviser to the Saxon Industrialists' Union, founded by himself. After an early inclination to the politico-social ideas of Friedrich Naumann (1860–1919) and collaboration with the latter's National Social Union (founded in 1896), he joined the National Liberal Party in 1903. His wife, whom he married in 1903, was a daughter of the Berlin industrialist Adolf Kreefeld. Of Jewish extraction, she was later to play a leading role in Berlin society under the Weimar Republic. She bore him two sons.

As editor of the Dresden paper *Sächsische Industrie* and as a Dresden city councilor (1906–12), Stresemann became thoroughly versed in commercial and municipal affairs. He was elected to the *Reichstag* as deputy for Annaberg from 1907 to 1912 and for Aurich from 1914 to 1918. His advocacy of the interests of middle-class tradespeople and his demand for further social legislation seemed too far-reaching to the powerful representatives of heavy industry on the right wing of his party. The consequent antagonism to him prevented his reelection to the presidium of the party in 1912; nor was he returned to the *Reichstag* by the elections of that year. Disappointed, he devoted his leisure to travel and study in the United States.

A member of the board of the Hansabund (from 1911), deputy chairman of his own Saxon Industrialists' Union (1911–18), executive member of the board of the German-American Commercial Union (1914–23), and chairman of the German Tea Industry's Union (1915–23), Stresemann ranked as one of the foremost figures in those great German business consortia which strove to influence politics. His financial independence, his acknowledged talent for organization, his skill at handling men, and his pronounced self-confidence paved the way for a brilliant political future. An active member of the *Kolonialverein* (under Pan-German inspiration) and a champion of Germany's naval program, he was an uncritical supporter of the *Weltpolitik* ("world policy") of William II's *Reich*.

**World War I.**—In World War I, Stresemann came forward as one of the most passionately vociferous exponents of Pan-Germanism and as a spokesman for extensive annexations of Polish, Russian, French, and Belgian territory. He made no secret of his hatred of the nations ranged against Germany. Over the National Liberals in the Reichstag he won ever-increasing influence as the closest collaborator of their leader, Ernst Bassermann (1854–1917). When Bassermann died, in July 1917, Stresemann succeeded to the leadership of the National Liberal group in the Reichstag, but leadership of the party as a whole passed to Robert Friedberg. In November, however, Friedberg was appointed vice-premier of Prussia, and Stresemann then succeeded to the party leadership also. Meanwhile, he had also been cooperating closely with the Supreme Command of the Army (Erich Ludendorff); and his ardent admiration for the navy had led him to call for unrestricted U-boat warfare. Likewise, as the parliamentary mouthpiece of the Supreme Command, Stresemann had struggled against the temperate policy of the chancellor, Theobald von Bethmann Hollweg (*q.v.*). The chancellor's downfall, in July 1917, was very largely brought about by Stresemann, in concert with Matthias Erzberger (*q.v.*); but Stresemann was unsuccessful in his plan to bring Bernhard von Bülow (*q.v.*) back to power. For a time Stresemann belonged to the Intergroup Committee (*Interfraktioneller Ausschuss*) in the Reichstag. This comprised prominent deputies of the Progressive, Centre, Social Democratic, and National Liberal parties who advocated a negotiated end to the war in accordance with the Peace Resolution voted by the majority of the Reichstag on July 19, 1917.

Notwithstanding the lack of unanimity among the National Liberals on the question of the Prussian *Dreiklassenwahlrecht* (whereby the voters in elections to the Prussian House of Deputies were divided into three classes according to the amounts paid in direct taxation) and the differences between the National Liberal group in the Reichstag and that in the Prussian *Landtag*, which stood farther to the right, Stresemann contrived to hold his party together. He declared himself in favour of abolishing the controversial *Dreiklassenwahlrecht*, hoping that the introduction of equal rights of voting would serve to strengthen the monarchy.

Up to the autumn of 1918, with most other German parliamentarians, Stresemann let himself be deceived about the seriousness of his country's military situation. While he had tacitly to renounce his former insistence on Germany's original war aims, he then brought his party to support the introduction of the parliamentary system with ministerial responsibility (*see GERMANY: History*). The "October Constitution" of 1918 corresponded to his ideas.

**The First Postwar Years.**—After the collapse of the imperial regime (November 1918), the versatile Stresemann accommodated himself soberly to the facts of a republican Germany. He remained active in politics. In December 1918, since the new German Democratic Party (led by Friedrich Naumann and Max Weber) did not want to receive into its ranks so well-known an annexationist and Pan-German as Stresemann, he took elements from the right wing of the National Liberals to form the German People's Party, a middle-class organization inclining still more to the right. In 1919 he was a member of the National Assembly, at Weimar, for the framing of a new constitution; and from 1920 onward he was a deputy in the new Reichstag. A convinced monarchist, hostile to the democracy of Weimar and to the Treaty of Versailles, Stresemann naturally disliked the republican constitution, to which he gave his assent only after an interval. The period from 1919 to 1923, which he spent mainly in opposition as a spokesman of nationalist opinion, was for him a time of preparation for greater tasks. During this period his German People's Party showed itself ready to enter into coalitions with the democratic parties; but at the time of Wolfgang Kapp's attempt to overthrow the regime (March 1920) Stresemann's attitude was highly ambiguous.

**Chancellorship.**—On Aug. 13, 1923, Stresemann became chancellor of the Reich at the head of a government of the "Great Coalition," comprising representatives of the Social Democrats, of the Centre, and of the German Democrats as well as of his Peo-

ple's Party. Whereas the crisis over the Ruhr (*q.v.*), with the "passive resistance" of the German population to the occupying forces of the Allies, had grown worse and worse under his predecessor Wilhelm Cuno and was precipitating the collapse of Germany's finances through inflation, Stresemann could read the situation correctly and brought the conflict to an end. For this decision he was vehemently attacked by the German National People's Party which stood for the extremists of the right.

Communist attempts at insurrection in Saxony and in Thuringia were put down by Stresemann's dispatch of troops of the Reichswehr (national forces) into those states in October. In Bavaria, where the local commander of the Reichswehr, Gen. Otto von Lossow, aligned himself with the dissident government of the monarchist Gustav von Kahr, the authority of Stresemann's government was restored after the failure of Adolf Hitler's *Putsch* of Nov. 8–9. In the Rhineland and in the Palatinate, however, separatist movements received the backing of the French authorities and were more difficult for the government of the Reich to suppress. Meanwhile, with the Rentenmark, Stresemann's finance minister Hans Luther achieved a stabilization of the currency an essential preliminary to the political rehabilitation of Germany.

When the Social Democrats, to the bitter distress of Pres. Friedrich Ebert, frivolously withdrew from the government, Stresemann on Nov. 23 was obliged to resign.

**Foreign Ministry.**—The next chancellor, Wilhelm Marx, a member of the Centre Party, took Stresemann as his foreign minister; and Stresemann remained in charge of foreign affairs under the successive chancellorships of Hans Luther, Wilhelm Marx again, and Hermann Müller, with their various coalition governments. Under his guidance Germany reached an understanding with the Western Powers by fulfilling to a considerable extent the obligations of the Versailles Treaty and by obtaining a reduction of its terms through negotiations. The beginning of reconciliation between Germany and France was especially notable, as Aristide Briand (*q.v.*) worked to the same purpose as Stresemann. The two statesmen shared the Nobel Peace Prize in 1926.

Stresemann was primarily concerned to solve the problem of reparations (*q.v.*) and to obtain security for Germany against any new application of sanctions like the French invasion of the Ruhr in January 1923. For him a general consolidation of the peace was a necessary preliminary to the restoration of Germany as a European Power. His immediate aim was to advance the eastern frontier at Poland's expense and to unite Germany and Austria, and his pursuit of this aim involved vigorous support of German minorities abroad. He saw clearly how Germany's central position in Europe furnished the possibility of alliance with the Western Powers or with the U.S.S.R.; and his realistic assessment of the international situation enabled him to exploit Anglo-French tensions in his diplomacy. He favoured the expansion of the Reichswehr beyond the numerical limits stipulated by the Versailles Treaty, as well as its clandestine rearmament and its development with Soviet help. In his efforts toward a rapprochement with the Western Powers he had the sympathetic collaboration of the British ambassador in Berlin, Lord D'Abernon.

Stresemann's success can be marked out in stages. In 1924 the Dawes Plan was signed, reorganizing the system of reparations on the basis of Germany's ability to pay. In 1925 the Pact of Locarno (*q.v.*) declared Germany's western frontier, as established in 1919 to be inviolable, under British and Italian as well as French and Belgian guarantee; provided for arbitration on matters in dispute, and gave assurances against further application of sanctions. The evacuation of the first zone of the Rhineland (*q.v.*) by the Allies ensued. In 1926 Germany was admitted to the League of Nations and the Treaty of Berlin, between Germany and the U.S.S.R., strengthened the relationship which the Treaty of Rapallo had inaugurated. In 1927 the Inter-Allied Military Commission was recalled from Germany. In 1928 Germany subscribed to the Kellogg Pact (*q.v.*) renouncing war. Finally Stresemann procured further revision of the system of reparations—which the Young Plan brought into effect, together with the evacuation of the Rhineland in advance of schedule, after his death.

Stresemann had to surmount formidable difficulties, including

resistances in Germany itself. His last meeting with Briand, at Thoiry on Sept. 17, 1926, gave rise to exaggerated hopes, but thereafter Franco-German reconciliation came to a standstill. Neither Germany nor France was ready for a cleansing of their relationship. Even so, Stresemann was enthusiastic over Briand's plan of 1929 for a united Europe, supporting it with economic arguments.

Stresemann's prestige brought a certain stability to the internal politics of the Weimar Republic. He had to pay heavily for his success, however. In order to get the requisite parliamentary approval for his policy he had to make continual appearances in the Reichstag, apart from the burden of public speaking and writing articles for the press. While the parties of the "Weimar Coalition" (Social Democrats, German Democrats, and Centre) generally supported him, it was often very difficult for him to rally his own party's right wing, which was dominated by the leaders of heavy industry, to his cause. In 1924 disapproval of his policy prompted some deputies to secede from his parliamentary group and to form their own National Liberal Union. As a former Pan-German, Stresemann was constantly on the defensive against the extreme nationalists. To a large extent, moreover, opposition to him within his own party was an aspect of the struggle against the republic, of which he had paradoxically become the guardian and the symbol even though he was at heart a monarchist. He was more popular abroad than in his own country. He died suddenly in Berlin on Oct. 3, 1929.

Scarcely any other political figure typifies so aptly as Stresemann does the transition from monarchy to republicanism in Germany. Imbued with the traditions of the imperial regime and conditioned by National Liberalism, he had developed into a successful parliamentarian. Yet for all his efforts he failed in the task allotted to him in internal politics: that of converting the Liberals of the right—first and foremost the German People's Party—to the ideas of Weimar. Immediately after his death his party fell to pieces: its sponsors among the electorate turned to the German National Party and to the National Socialists.

Stresemann's diplomatic talents and his success in foreign affairs are incontestable. As the exponent of "national realism" (*nationale Realpolitik*) against the "pacifist policy of renunciation," he worked consistently for the restoration of the Reich as a great power. His conception of the national state, one aspect of which (the incorporation of Austria) was unmistakably inspired by "Great German" ideology, reveals the limitations of his political thinking. It is quite unjustifiable to claim him as a precursor of any movement for European integration. He relied on further successes for the policy of peaceful revisionism which he had so promisingly inaugurated.

Stresemann is sometimes judged in a controversial way. After the enforced silence about him during the National Socialist period, a Stresemann revival set in from 1945, at first in propaganda, then in scholarly writing too, glorifying his foreign policy in terms of the later Pan-European idea. About 1950, however, with the opening-up of his voluminous political papers, a one-sided portrait came to be drawn of a nationalist politician cleverly pursuing his ambitious purposes under cover of slogans such as "League of Nations," "spirit of Locarno," "equality of rights," etc. Later German research into his life and work represents Stresemann as a master of politics who transcended his origins and achieved extraordinary results.

Stresemann's published writings, catalogued by G. Zwoch, *Stresemann-Bibliographie* (1953), include *Macht und Freiheit* (1918), *Von der Revolution bis zum Frieden von Versailles* (1919), *Reden und Schriften*, 2 vol. (1926), and *Vermächtnis*, 3 vol. (1932-33).

**STRETFORD**, a municipal (1933) and parliamentary borough of Lancashire, Eng., adjoining Salford and Manchester to the northeast. Pop. (1961) 60,364. Area 5.5 sq.mi. (14.2 sq.km.). It contains a considerable part of the Trafford Park industrial estate, between the Bridgewater Canal and the Manchester Ship Canal (see MANCHESTER). Old Trafford, the Lancashire County Cricket Club's ground, is in the town. Longford Hall houses the town's art collection and Longford Park is the biggest of Stretford's five parks. There is a civic theatre. The two manors of Stretford and Trafford have, since about 1260, descended in the family of de Trafford. The name of the town refers to the crossing of a ford by the Roman road (*strata*) from Chester to Manchester.

**STREUVELS, STIJN** (pseudonym of FRANK LATEUR) (1871- ), whose novels and short stories are among the masterpieces of modern Flemish prose, was born at Heule, near Kortrijk, on Oct. 3, 1871. The nephew of the priest and poet Guido Gezelle (q.v.), he discovered his literary gifts while at school at Aveigem. He became a master baker there but found time to learn German, English, Danish, and some Russian and, after 1892, to write his first stories, stimulated by his reading of some French realistic stories and the revelation he found in Impressionist painting. He contributed to the periodical *Van Nu en Straks* (see BELGIAN LITERATURE: Flemish) and, in 1899, achieved fame with his first collection, *Lenteleven* (Eng. trans. *The Path of Life*, 1915). In 1905 he settled in the village of Ingoigem and devoted himself to writing.

Streuvels finds his subjects in the village life of southwest Flanders between Scheldt and Lys—an isolated and agrarian Flanders that no longer exists—defining his chosen locality by precise reference to dialect and folklore. But he is no mere chronicler. His keen observation is enlarged and enriched by his imaginative power, his feeling for atmosphere, and his wealth of language. He creates a world of his own, at once elemental and true to life. In this world, nature is an ever-present force—a nature described with a visionary power resembling that of Van Gogh. Although his descriptions are often long, they are never irrelevant to his theme, for his characters are closely bound to the land (e.g., in *Langs de Wegen*, 1902, Eng. trans. *Old Jan*, 1936; *Minnehandel*, 1903; *De Vlaschaard*, 1907). In his later works, where he deals with the conflict between nature and civilization, and with moral, religious, and social problems, he is less successful (*De teleurgang van den Waterhoek*, 1927; *Alma*, 1931; *Levensbloesem*, 1938). At his best he is a master of characterization, especially in his presentation of farmers and farm workers, who struggle against the land and against destiny (this is most clearly seen in *De Vlaschaard*, his masterpiece, and in *Het leven en de dood in den ast*, 1926), and of children, whose fresh outlines introduce a note of tenderness into his cosmic and visionary view of life (e.g., in "Lente," in *Lenteleven*; *Het Kerstkind*, 1911; and *Pruiske*, 1922). His epic-lyrical prose style, perfectly suited to his subject, is among the best of its period.

Janssen, *St. Streuvels and zijn Vlaschaard* (1946); A. Demedts, *St. Streuvels* (1955); R. van de Linde, *Het oeuvre van Streuvels, sociaal document* (1958). (R. F. Ls.)

**STRICKLAND, WILLIAM** (1787-1854), U.S. architect and engineer, designed several public buildings and Washington's marble sarcophagus at Mount Vernon. Born in Philadelphia, Pa., in 1787, he first became known as an artist, although he studied architecture under Benjamin Latrobe. In 1810, however, he designed the Masonic Hall in Philadelphia and was thus well launched as an architect. Although the hall was Gothic in design, Strickland later turned to the neoclassical style, and his next important work, the United States Bank in Philadelphia, took the Parthenon for its inspiration. Strickland also designed the Merchants' Exchange building, the United States Naval Asylum, the United States Mint, and the United States Custom House, all in Philadelphia.

His engineering projects were nearly as well known as his architectural. In 1825 he was sent to Europe to study internal improvements and on his return did much to encourage the construction of the original line of the Pennsylvania Railroad Company,

one of the first designed to carry passengers in the United States. He also constructed the Delaware Breakwater, a commission he received from the U.S. government. At the time of his death he was in Nashville, Tenn., superintending the construction of the state house, which he designed and which is regarded by many as his best work. He died in that city April 7, 1854, and by a special act of the state legislature was buried in the building.

He was the author of several technical publications relating to engineering and architectural projects which he headed.

**STRIGGIO, ALESSANDRO**, the Elder (c. 1535–1587), Italian composer and instrumentalist, one of the native masters who carried the Italian madrigal to its final perfection, was born in Mantua about 1535, of noble parentage. Apart from a stay in Florence (c. 1560–70) and a journey to England (1567), he spent his life in Mantua, where he died probably on Sept. 22, 1587. Striggio's fame lies in his seven collections of madrigals (1560–97) and his quasi-dramatic pieces, one of which depicts women chattering on washday. He was a brilliant violist, lutenist, and organist, and some of his *intermedi* and one of his few motets are early examples of Renaissance instrumentation.

See A. Einstein, *The Italian Madrigal* (1949).

(B. L. Tr.)

**STRIJDOM** (STRYDOM), **JOHANNES GERHARDUS** (1893–1958), South African statesman and extreme advocate of the policy of apartheid (*q.v.*), was prime minister of the Union of South Africa from 1954 to 1958. Born at Willowmore, Cape Colony, on July 14, 1893, he was educated at Victoria College, Stellenbosch, and afterward joined his father, P. G. Strijdom, on his ostrich farm in the Willowmore district. He moved in 1914 to Pretoria, where he entered the public service and in 1917 qualified in law at Pretoria University. He set up as an attorney at Nylstroom, Transvaal, in 1918, and soon became active in the Nationalist Party. In 1929 he was elected member of parliament for Waterberg, Transvaal, a seat he held until his death.

Strijdom first became a national figure in 1934, when J. B. M. Hertzog, leader of the Nationalist Party, and J. C. Smuts, leader of the South African Party, joined forces to form the United Party, and Strijdom was the only Transvaal Nationalist member of Parliament to refuse to follow Hertzog. He afterward became the Transvaal leader of D. F. Malan's new Nationalist Party and was most energetic in building it up. When the Nationalists won the 1948 election, Strijdom became minister of lands and irrigation in Malan's Cabinet, where he devoted himself to maintaining white supremacy in South Africa. On the retirement of Malan in November 1954 he was elected leader by the parliamentary caucus of the Nationalist Party, in preference to Malan's candidate, N. C. Havenga, and became prime minister on Dec. 3, 1954. His succession marked the ascendancy of the extreme Transvaal wing of the party over the more moderate Cape wing.

Strijdom's government pushed vigorously ahead with apartheid, radically changed the composition of the Senate in 1955, and by thus gaining the necessary two-thirds majority in a joint sitting of both houses of Parliament, in 1956 placed the Cape Coloured voters on a separate electoral roll. Strijdom fell ill in December 1957 and died in Cape Town on Aug. 24, 1958.

(L. M. T.)

**STRIKES AND LOCKOUTS.** Strikes (often called turn-outs or sticks in the early 19th century) are concerted refusals by employees to work under the conditions required by employers. Lockouts, strictly speaking, are occasions on which employers close their establishments against their employees until they accept the terms offered them; but the word lockout is often used, especially by workers, to cover occasions on which the employer attempts to worsen the terms of employment and the workers abstain from work in protest. Lockouts in the strict sense became uncommon in the first half of the 20th century; in earlier years they occurred when an employer or group of employers was attempting to ban union membership and refused employment to workers who would not sign a pledge not to belong to a trade union. Later they arose most often when a body of employers retaliated against a strike at a particular works by closing all factories until the strikers returned to work. When the word lockout is used in its wider sense the distinction between it and a strike is often hard to draw, and workers will describe as a lockout what the employers call a

strike. Statistically, no separation can be made, and strikes and lockouts are lumped together under the heading of work stoppages, or labour disputes.

Of the various types of strikes and lockouts, the simplest is the dispute about wages or conditions of employment, or about some special issue of discipline or labour union practice, when the strikers (or lockers-out) are the parties directly involved. Sympathetic strikes or lockouts are those in which persons or associations not directly involved in the original dispute go on strike or close their establishments in sympathy with one of the original parties. A jurisdictional strike is a dispute between two unions, both of which claim that certain work is within their exclusive jurisdiction. General strikes may be either very extensive sympathetic strikes or work stoppages over a wide range of industries for a common object. The political general strike belongs to the latter type; it can be either a mere protest strike, called for a single day or for a limited period, or a strike designed to last until it has achieved its purpose or failed, as in the German general strike against the Kapp Putsch of 1920. The British general strike of 1926 was simply an extended sympathetic strike in support of the Miners' federation, whereas the threatened strike of 1920 against British participation in the Soviet-Polish war belonged to the same class as the strike against the Kapp Putsch. A special variety of strike, which may belong to any of the foregoing categories, is the sit-down or stay-in strike (stay-down, in mining) in which the strikers occupy their places of employment and either do no work or attempt to carry on production on their own account (as in the Italian stay-in strikes after World War I). The stay-in strike was extensively used in France in the 1930s at the time of the popular front and is also a familiar technique among native workers in colonial areas. It was introduced into the United States in the 1930s.

The general strike as actually practised has to be distinguished from the general strike as aspiration—sometimes called the social general strike—which is a mass strike of workers designed to bring about a social revolution and the establishment of a workers' society. Its earliest advocates were the anarchist-communists (see A. Roller, *The Social General Strike*, 1905); and the idea was taken up by the French syndicalists. It was Georges Sorel, author of *Reflections on Violence* and other books of syndicalist theory, who introduced the idea of the general strike as a "social myth," inspiring working-class revolutionary feeling and giving a heightened meaning to ordinary strike action, even if in practice it never occurred. The French syndicalists also introduced the conception of *la grève perlée* (sometimes anglicized as "the strike with knobs on") by way of contrast with *la grève aux bras croisés* ("the strike with folded arms"), the former being accompanied by acts of sabotage or violence.

Strikes may be either spontaneous or organized. A great many strikes have begun as spontaneous reactions by a group of workers to a particular grievance, such as the dismissal of a fellow-worker whose "victimization" for union activity was suspected, or the employment of unskilled workers on jobs normally reserved for skilled workers, or the cutting of a piecework rate, or any of a hundred other things. Such sudden strikes may become organized subsequently, if a union takes them up, or sometimes if the strikers choose leaders of their own. Strikes may also be either official or unofficial: they are official when they are called or approved by a labour union, which takes control of the proceedings and of any negotiations designed to settle them; unofficial (wildcat) strikes are either strikes apart from unions, or strikes called by union branches or districts without the support of the union as a whole in accordance with its rules. Since, in many countries, organized national collective bargaining has been introduced into most industries and collective agreements have laid down procedures to be gone through before an official strike can be called, an increasing proportion of all strikes tends to be unofficial—for example, a group of workers, tired of waiting to have its grievance dealt with by dilatory negotiating procedures, strikes contrary to the provisions of a national or other collective agreement. The proportion of unofficial strikes is also increased when laws have been passed either forbidding strikes or imposing a compulsory period of de-

lay for investigation before they can be lawfully called (the Lemieux system, used in Canada, and called after its proposer, Rodolphe Lemieux). Groups of workers will often dare to strike "against the law" when unions, fearful of having their funds attacked or their recognition by the state suspended or removed, hesitate to endorse a strike and so make it official. See further LABOUR LAW; GENERAL STRIKE.

(G. D. H. C.)

## UNITED STATES STRIKES

Even before the American Revolution a few strikes occurred in the American colonies. During the early years of the republic most labour disputes were on a small scale for higher wages or the ten-hour day. To maintain their standards of living during periods when the cost of living was on the increase, workers organized unions to gain financial and moral support in their struggles for higher wages. While prosperity continued, the workers' demands tended to be granted, but the financial panic of 1837, with its consequent unemployment, meant defeat for the trade unions on the economic front.

After the Civil War, unionism took on a national character. The first strike of nation-wide extent was on the Pennsylvania and the Baltimore and Ohio railroads in 1877, at the depth of a prolonged depression. The Pittsburgh freight yards of the Pennsylvania railroad were burned and looted. State troopers brought in from Philadelphia because of the inaction of local authorities and the unreliability of local state troopers were forced to surrender. The strike, which many feared might be the U.S. counterpart of the Paris Commune, was quelled by the dispatch of units of the U.S. army.

On May 1, 1886, approximately 340,000 workers went on strike in response to a call by the national trade union federation, which became the American Federation of Labor in 1886, to secure the eight-hour day. Explosion of a bomb in Haymarket square in Chicago, Ill., on May 4, 1886, supposedly by anarchists, and the consequent public clamour against radicalism and unionism was blamed by Samuel Gompers for seriously hurting the eight-hour-day movement. A revival of the demand for an eight-hour day occurred in 1890, when carpenters struck throughout the nation and were generally successful in achieving their objective.

Skilled organized workers at the Homestead, Pa., plant of the Carnegie Steel Co. in July 1892 refused to accept a wage reduction, and in the process gained the support of the unorganized workers. Thereupon Henry C. Frick, general manager of the company, shut down the entire plant and refused to negotiate any further with the Amalgamated Association of Iron, Steel and Tin Workers, until then the strongest union in the world. As the strike issue settled down to one of continued union recognition, Frick imported strike-breakers and armed guards. In the clash which ensued between the guards and strikers, several were killed on both sides. The strike ended in U.S. unionism's most decisive defeat. Organized labour's defeat in the American Railway union strike, or the so-called Pullman company boycott of 1894 was of another order. The union, young and weak, instituted a sympathetic strike to assist the Pullman local's resistance to a 25% wage cut. Violence and mass destruction of property occurred, centring in the Chicago yards. The railroad asked for federal intervention, and 2,000 federal troops were sent to Chicago. However, the strike was really broken by the issuance of injunctions in the federal courts secured at the insistence of the U.S. attorney general on the basis of the Sherman Anti-trust law as one of the grounds.

The successful strike of the bituminous coal miners in 1897 resulted in establishment of an agreement for the so-called central competitive field, with Illinois as the union's stronghold for decades thereafter. The collective agreement, after an apparently hopeless strike begun with an empty union treasury, founded an "industrial government" based on reciprocal rights and obligations of both parties and pointed the way in all of the coal industry and other industries as well. In 1902, 150,000 anthracite miners struck to achieve a reduction of hours, an increase in wages and recognition of their union. Violence occurred in areas where strikebreakers were hired to mine coal. To preserve order the national guard was sent to certain cities. As winter came, the

situation grew worse, and Pres. Theodore Roosevelt intervened and arranged for arbitration. The miners won a 10% increase in wages and a shorter working day, but their union was not recognized. The outstanding figure of this struggle was the miners' leader, John Mitchell, who sustained the hope of his polyglot following and won public sympathy by his moderation.

The next big strike was that of the coat and suit makers (women's) in 1910. It produced a second major pattern of industrial government, added to that of the soft-coal miners. Following a two months' strike in New York, a "protocol of peace" established a tripartite board to settle differences between the manufacturers and the union under the agreement. Louis D. Brandeis, later on the United States supreme court, mediated in the strike and devised a compromise in the "preferential union shop" in lieu of the closed shop vainly demanded by the union. This proved a major invention. A four-months' strike against Hart, Schaffner and Marx in Chicago established a similar pattern in the men's division. In this strike, as in the working of the agreement, Sidney Hillman, later a major leader in U.S. unionism, made his debut.

Stable industrial government in the bituminous coal industry was constantly menaced by nonunion competition. Continuous efforts were made by the United Mine Workers to organize the West Virginia mines; but the operators, with state support, succeeded in repelling organization. Union members were evicted from company houses and forced to live in tent colonies, and in Feb. 1913, an armed railway train machine-gunned a miners' tent colony at night. A similar incident of industrial autocracy occurred in Colorado. In 1913-14 the national guard machine-gunned miners' tent colonies, and the miners retaliated by killing mine guards and destroying mine property. Federal troops were called to bring order in April 1914, but the strike was not called off until December.

An attempt made to organize the iron and steel industry during and immediately after World War I was a major effort to recoup labour's loss in the Homestead strike in 1892. About 350,000 responded to a strike started in Sept. 1919, but strike-smashing was employed extensively. The men held out for six weeks at the cost of 18 lives, and then mass surrenders began.

**The New Deal.**—With the New Deal, strikes began to evolve to a new pattern of diminishing violence because of a more considerate treatment of strikers by government and employers. Yet this may be said to date only from the "little steel" strike of 1937 and the La Follette committee investigation of denial of rights to wage earners.

A longshoreman's strike in San Francisco, Calif., in May 1934 developed into a general strike. Union recognition and control of the hiring halls, in essence the closed shop, and better wages and hours were the issues. Serious rioting began when the employers attempted to operate the docks by force. The California national guard was called out. Labour became steadily more embittered, and in July sympathetic strikes started, and the principal highways into the city were closed. The general strike called on July 16 lasted four days, but the strike committee permitted the entrance of food trucks. The longshoremen's leader in this strike was Harry Bridges, subsequently well known in Pacific coast and Hawaiian industrial relations.

To force "little steel" recognition of the Steel Workers' Organizing committee (C.I.O.), a strike was called in May 1937. The struggle was attended by considerable violence and, although "big steel's" recognition of the Steel Workers' Organizing committee had occurred early in 1937, "little steel" (the independent producers) continued to resist unionization for a few more years.

**World War II and After.**—Prior to the attack on Pearl Harbor two allegedly Communist-led strikes threatened to hold up the national defense program. In June 1941 leaders of the United Automobile Workers' local at the North American Aviation Co. in Inglewood, Calif., called a strike in violation of an interim agreement negotiated with the aid of the National Defense Mediation board. This unauthorized strike was broken through plant seizure by the government and a dispatch of troops. A strike at the Allis-Chalmers plant in Milwaukee, Wis. (1941), crippled vital defense production.

Production losses caused by wartime strikes were relatively small except for soft-coal mining. An outgrowth of two strikes during 1943 was the Smith-Connally or War Labor Disputes act.

With the termination of the no-strike pledge at the end of the war came renewed industrial warfare. The restriction of wage increases during the war, fear of unemployment and some reduction in income because of "cutbacks," and the conviction that organized labour was to be subjected to a concerted employer attack created a favourable climate for widespread strikes. It was expected that the events of World War I and its aftermath would be repeated. In that war the wartime truce had been followed by a triumphant employer counterattack which not only "contained" unionism but regained most of the ground lost by management. Just as 1919 had seen a new record in the number of strikers, it was expected that 1946 might approach that record and possibly bring about a comparable defeat for labour. What happened was something entirely different: prosperity held and the unions continued to gain in membership, notably in the newest of the New Deal-sponsored unions.

A number of the postwar strikes were industry-wide, and most of them were of considerable duration. During the 12-month period following V-J day, work stoppages resulted in almost 12,000,000 man-days of idleness. Strikes were called in the oil, lumber, auto, steel, electrical manufacturing, meat-packing, coal, railroad and maritime industries. A strike by the United Automobile Workers against General Motors began in Nov. 1945 and continued until March 1946. The leader of that strike, Walter Reuther, publicly championed the consumers' cause as well as that of the strikers. He said that he sought no wage increase that might result in a rise of the prices of cars—but he was certain that a wage increase could be met out of the corporation's accumulated profits. Debates between management and labour spokesmen about the ability of corporations to increase wages without at the same time increasing prices continued in following rounds of negotiation in the automobile and other basic industries, and the issue was still debated on the national level in the 1960s. The bituminous coal miners were on strike from April 1 to May 29, 1946, interrupted by a truce from May 13 to May 27. The railway trainmen and engineers struck on a nationwide scale for two days in May 1946 but were defeated by Pres. Harry S. Truman's radio appeal. Smaller but equally crucial strikes were those of the tugboat and building employees in New York and the public utility strike in Pittsburgh.

On the all-important wages question, the matter arranged itself in three "rounds" over 1946-48. Peculiar to this period was the importance of "pattern settlements." The first settlement reached in a mass-production industry tended to set a pattern which all other industries accepted. As the cost of living became stabilized, unions turned their attention to nonwage demands, such as employer-financed pension and social insurance programs. This demand was stimulated by the inability of unions to break the "little steel" wage formula during the war and gained added momentum from an agreement signed in 1946 between the United Mine Workers and the government in which a health and welfare fund was set up to be financed by a contribution of five cents on each ton of coal mined. From coal, "social security by contract" spread to the other basic industries.

The postwar years intensified the periods of industrial strife in the bituminous coal industry. Work stoppages were variously termed walkouts, memorial holidays, stabilization periods and just plain strikes. Since the industry was a "sick industry"—the coal demanded by the nation could be produced if the miners worked only three days a week—the union assumed responsibility for stabilizing production. Industrial government in the industry at times seemed to be dominated by a labour autocracy under John L. Lewis. But Lewis was careful to promote the welfare of his men. Action for contempt of court under the emergency provision of the Taft-Hartley act failed in the 1949-50 strike, as the union and its leaders gained immunity in complying outwardly with a court order to resume work, but without actually doing so.

The steel strike of 1949 typified the new day in industrial conflict. While the cost in dollars was great, the jails were empty.

Not a cent was spent on strikebreakers, tear gas, riot guns or arms of any kind. There was no loss of human life. This absence of violence, formerly so prevalent in U.S. labour disputes, stemmed from the Wagner act, the rise of a new kind of employer and a well-disciplined union membership.

Following the outbreak of the Korean war, the number of work stoppages increased sharply. In 1950 there were 4,843 stoppages, as opposed to 1948 with 3,419 stoppages. There had been 4,985 in 1946, however. The demand for wage increases came to the forefront as unions proposed and obtained increases in anticipation of federal wage controls. Following the establishment of federal wage controls in 1951, the unions once again shifted their emphasis to demands for fringe adjustments (e.g., vacation and holiday pay, shift differentials and overtime). This policy continued into 1952-53 as the cost of living became stabilized and started to decline. In the decade following World War II the peak in work stoppages occurred in 1953, with 5,091. The number dropped to 3,468 in 1954 and then rose to 4,320 in 1955.

Among the outstanding events of the period following the 1949 recession was the contract signed by United Automobile Workers, C.I.O., with the General Motors corporation. The five-year contract provided for cost-of-living adjustments in hourly wage rates, provided for a pension fund and established a union shop. These negotiations were harmoniously conducted and gave evidence of the effect that expanding business activity and sustained near capacity production levels had on labour-management relations. This settlement influenced the peaceful conclusion of wage agreements made by the Chrysler and Ford companies with the U.A.W. in 1950. Another important feature of labour-management relations after the outbreak of the Korean War was the active participation of the federal government in the settlement of labour disputes.

The Wage Stabilization board was authorized in April 1951 to investigate and recommend settlement in any dispute which was not resolved by collective bargaining or mediation, which threatened national defense, where the dispute was referred to the board by the parties involved or by the president of the United States. In 1951 the president referred five disputes to the board for settlement, in the copper refining and transport equipment industries. Also in 1951 the president referred the important steel dispute to the board. The steel union demanded an hourly wage increase and fringe benefits including shift premiums and holiday pay. The board recommended a wage increase and acceptance of some form of union shop. This recommendation was criticized by industry members because it threatened the anti-inflationary program of the federal government and it imposed a union shop on the industry. The union issued a strike notice in April 1952 when negotiations broke down. In an effort to avert the strike, the steel plants were seized by the federal government in April 1952. This seizure was declared unconstitutional by the U.S. supreme court in June 1952, and the president directed return of the mills to the owners. Immediately following the return of the mills the steel workers went out on strike.

This steel strike lasted 53 days and was responsible for one-half of the 55,000,000 man-days lost in 1952 through work stoppages. Steel production was not resumed until a new contract was signed granting an hourly wage increase and some of the fringe demands. Following the wage increase the acting defense mobilizer ordered the Office of Price Stabilization to authorize increases in the price of basic steel.

The government also participated directly in the settlement of two major railway disputes. Following an unsuccessful attempt to settle an 18-month dispute between the rail carriers and the major railway unions the government prevented a walkout by seizing the railways in Aug. 1950. The dispute centred about the unions' demands for a 40-hour week for yard workers and rules changes for road service employees. A settlement of the dispute between the railways and the switchmen was reached in Sept. 1950. The dispute with the trainmen ended in May 1951. However an agreement between the railways and the other operating unions was not reached for another year. Consequently federal operation of the railroads ended in May 1952.

Strike activity in 1953 measured in total time lost by workers involved was relatively low but, when measured in the number of strikes, was high. Most of these strikes involved demands for wage increase. One notable exception was the strike of the United Hatters, Cap and Millinery Workers against the Hat Corporation of America to prevent the transfer of work from Norwalk, Conn., to another plant. It lasted more than a year, and a formula was finally found which guaranteed the right of the company to determine its production policy and gave the workers some protection against sudden shifts in operation.

The number of workers involved and the number of disputes rose markedly in 1955. Several disputes involved large numbers of workers and were bitterly contested. The strike against the Southern Bell Telegraph and Telephone company, which lasted 72 days, as well as the strike of nonoperating workers on the Louisville and Nashville railroad, which lasted 57 days, were attended by violence and bitter recriminations. The latter dispute hinged upon the refusal of the carrier to accept a health and welfare plan, and the former was over wages and arbitration of certain kinds of disputes. On the other hand, the strike of New England textile workers against a number of mills in that area which lasted 90 days at some mills was free from violence. One of the bitterest strikes in the 1945-55 period was that of 70,000 workers in the International Union of United Electric Workers against the Westinghouse Electric and Manufacturing Co. This strike lasted almost six months, and was bitterly fought on the picket line.

In 1959 the number of man-hours lost because of strikes rose to 69,000,000, the highest figure since 1946. The main reason for the high total that year was the prolonged steel strike that alone caused 42,000,000 man-days of idleness. In the 1960s Presidents Kennedy and Johnson both played prominent roles in preventing or terminating strikes. In 1962, for example, Kennedy invoked the emergency powers of the Taft-Hartley act to halt four strikes affecting major industries. President Johnson intervened to avert a strike over a long-standing dispute in the railroad industry and in 1965 did the same when a steel strike was threatened.

The impact of automation in the 1960s caused labour disputes in certain industries, particularly newspaper publishing where electronic computers for rapid automatic typesetting were introduced. In 1962-63 a strike stopped publication of the two leading newspapers in Cleveland, O., for 129 days; in New York city the leading papers were shut down by a strike that began on Dec. 8, 1962, and lasted 114 days. Another strike caused by the automation problem stopped publication of several New York papers in Sept.-Oct. 1965.

**STRINDBERG, (JOHAN) AUGUST** (1849-1912), the greatest Swedish playwright, who exercised a profound influence on the drama, especially in Europe and the United States. novelist, short-story writer and poet, was born in Stockholm, Jan. 22, 1849. He was the son of a steamship agent and a former waitress, and had an unhappy childhood, marred by emotional insecurity, as he relates in his remarkable autobiography *Tjänstekvinnans son* (1886; Eng. trans., *The Son of a Servant*, 1913). He studied intermittently at Uppsala university, never taking a degree. He had to earn his living by working as a freelance journalist in Stockholm, among other occupations. Meanwhile he struggled to complete his first important work, the historical drama *Mäster Olof* (1872; Eng. trans., 1931), on the theme of the Swedish reformation, influenced by Shakespeare and by Ibsen's *Brand*. The Royal theatre's rejection of *Mäster Olof* deepened his pessimism and sharpened his contempt for official institutions and

STRINDBERG: LITHOGRAPH BY EDVARD MUNCH, 1896

traditions. He continued to revise the play—later recognized as the first living piece of modern Swedish drama—for several years, and this delayed his development as a dramatist of contemporary problems.

In 1874 he became a librarian at the Royal library, and in 1875 met the Finno-Swedish Siri von Essen, then the wife of a guards officer; two years later they married. Their intense but ultimately disastrous relationship ended with divorce in 1891, when Strindberg, to his great grief, lost the custody of the children. At first, however, marriage stimulated his writing, and in 1879 he published his first novel *Röda rummet* (Eng. trans., *The Red Room*, 1913), a satirical account of

abuses and frauds in Stockholm society: this was something new in Swedish fiction, and made its author famous.

He also wrote more plays, of which *Lycko-Pers resa* (1881; Eng. trans., *Lucky Peter's Travels*, 1931) contains the most biting social criticism. In 1883, after publishing *Det nya riket* ("The New Kingdom"), a withering satire on contemporary Sweden, Strindberg left Stockholm with his family and for six years moved restlessly about the continent. The first volume of his collection of stories *Giftas* (1884; Eng. trans., *Married*, 1913) led to a prosecution for blasphemy; he was acquitted, but the case affected his mind, and he imagined himself persecuted, even by Siri.

He returned to the drama with new intensity, and the conflict between the sexes inspired some of the outstanding works written at this period, such as *Fadren* (1887; Eng. trans., *The Father*, 1930), *Fröken Julie* (1888; Eng. trans., *Lady Julie*, 1930) and *Fördringsägare* (1888; Eng. trans., *The Creditor*, 1914). In these bold and concentrated works he combined the technique of dramatic naturalism with his own conception of psychology and thereby inaugurated a new movement in European drama. *Hemsöborna* (1887; Eng. trans., *The People of Hemsö*, 1959), a vigorous novel about the Stockholm skerries, always one of Strindberg's happiest sources of inspiration, was also produced during this intensively creative phase.

The years after his return to Sweden in 1889 were lonely and unhappy; in 1892 he went abroad again, to Berlin. His second marriage, to a young Austrian journalist, Frida Uhl, followed in 1893: they finally parted in Paris in 1895. A period of literary sterility, emotional and physical stress, and considerable mental instability, culminated in a kind of religious conversion, the crisis which he described in *Inferno* (1897; Eng. trans., 1912). Strindberg had earlier moved from Christianity to atheism by way of deism; scientific studies (1894-96) led to experiments with alchemy and to theosophy.

His new faith, coloured by Swedenborgian mysticism, recreated him as a writer. The immediate result was the drama in three parts, *Till Damaskus* (1898; Eng. trans., *The Road to Damascus*, 1939), in which he depicts himself as "the Stranger," a wanderer seeking and finally finding spiritual peace: another character, "the Lady" resembles both Frida Uhl and Siri von Essen.

By this time Strindberg had again returned to Sweden, settling first in Lund, then, in 1899, in Stockholm, where he lived (after 1908 in his apartment *Blå Tornet*—"the Blue Tower") until his death. The summers he often spent among his beloved skerries. His view that life is ruled by the "Powers," punitive but righteous, was reflected in a series of historical plays which he began in 1889. Of these *Gustav Vasa* (1899; Eng. trans., 1931) is the best, masterly in its firmness of construction and characterization and its vigorous dialogue. In 1901 he married the young Norwegian actress Harriet Bosse; in 1904 they parted, and again Strindberg lost the child, his fifth.

Yet out of this "spring in winter," as he called it, came inter

alia the plays *Dödsdansen* (1901; Eng. trans., *The Dance of Death*, 1929), *Kronbruden* (1902; Eng. trans., *The Bridal Crown*, 1916) and *Drömspelet* (Eng. trans., *A Dream Play*, 1929), as well as the charming autobiography *Ensam* ("Alone," 1903) and some lyrical poems. Renewed bitterness after his parting from his wife provoked the grotesquely satirical novel *Svarta Fanor* ("Black Banners" pub. 1907), which attacked the vices and follies of Stockholm's literary coteries, as Strindberg saw them. *Kammarspel* ("Chamber Plays," 1907), written for the little Intima theatre, which Strindberg ran for a time with a young producer, August Falck, embody further developments of his dramatic technique: of these, *Spöksonaten* (Eng. trans., *The Ghost Sonata*, 1929) is the most fantastic, anticipating much in later European drama. His last play, *Stora Landsvägen* (Eng. trans., *The Great Highway*, 1954), a symbolic presentation of his own life, appeared in 1909.

Up to the last Strindberg debated current social and political ideas (returning to the radical views of his youth) in polemical press articles, while his philosophy was expounded in the aphoristic *Blå Böcker* (1907-12; Eng. trans., *Zones of the Spirit*, 1913). He died of cancer on May 14, 1912, in Stockholm, ignored in death, as in life, by the Swedish Academy, but mourned by his countrymen as their greatest writer. On Swedish life and letters he has exercised a lasting influence and is admired for his originality, his extraordinary vitality and his powerful imagination, which enabled him to transform autobiographic material into dramatic dialogue of characteristic brilliance.

The pregnant, colloquial style of Strindberg's early novels and, especially, of his short stories, brought about a long overdue regeneration of Swedish prose style, and *Tjänstekvinnans son* gave perhaps the strongest impulse since Rousseau's *Confessions* to the publication of discreditable self-revelations. His greatest influence however was exerted in the theatre, through his critical writings (such as the introduction to *Fröken Julie*), his plays and the devices of production which their staging enjoined. The continuous, brutal action and phonographic dialogue of *Fröken Julie* and other plays written between 1887 and 1893 reached the *ne plus ultra* of naturalistic drama, as presented simultaneously in André Antoine's Théâtre Libre in Paris. With the later phantasmagoric plays, such as *Till Damaskus*, *Drömspelet* and *Spöksonaten*, Strindberg then led that section of the revolt against stage realism issuing in the expressionist drama, which was developed mainly in Germany after 1912 by Fritz von Unruh, Franz Werfel, Ernst Toller and Georg Kaiser, but left notable traces elsewhere, as in the drama of Sean O'Casey, Elmer Rice, Eugene O'Neill, Luigi Pirandello and Pär Lagerkvist.

(B. M. E. M.; B. W. D.)

**STRINGED INSTRUMENTS** owe their existence to the musical properties inherent in an elastic filament when it is made to vibrate regularly by being suitably energized while stretched between two fixed points. The tension, length, thickness and mass of the filament, or string, all affect the rate of vibration and consequently the note it will produce. The shorter or tenser the string, the higher the note; a heavy string produces a lower note than a lighter one of the same length and tension.

**Resonators.**—For musical purposes, the stretched string is not enough; it must, if the result is to be musically acceptable, be in

contact with some sort of resonator that is capable of radiating vibrations. All stringed instruments therefore possess a resonant body, usually of wood, the essential feature of which is always the soundboard or belly, which lies directly under the strings and receives their vibrations through the bridge over which they are stretched. The form of the belly varies with the instrument, but it is in effect a thin diaphragm capable of responding to the vibrations transmitted by the bridge and of propagating them freely and instantaneously all over its area, which is made as large as practical considerations allow. Straight-grained pine is the favoured material for the bellies of the majority of European instruments on account of its excellent resonant properties and the rapid and even distribution of musical vibrations both along and across the grain. A stretched skin membrane has, however, been used, notably in the European banjo, the Indian *sarinda* and *sarangi* and the Arab *kamanga* and *rabab*. The wooden bellies of all developed instruments are reinforced in a variety of ways by cross-bars glued to the underside; these bars serve as girder stiffeners and prevent the belly from sinking under pressure of the strings, while preserving its general flexibility and response. Such bars also assist in the propagation of transverse vibrations across the pine belly. The bowed stringed instruments, whose string tensions and bridge load are relatively high, employ a distinctive vertical strut, the soundpost, which not only gives greater support to the belly but also is a vital agent in the tonal adjustment of the instrument (see VIOLIN FAMILY).

With only a few primitive exceptions, the belly forms the "lid" of a box that is in fact the body of the instrument. If the air space thus enclosed is to resonate freely it must be in contact with the surrounding atmosphere, and it is usual to cut soundholes through the belly to ensure this. The form of the soundholes varies enormously, but to some extent their shape, position and area are functional, serving to regulate both the stresses to which the belly is subject and the effect of the resonant air space. In the violin family especially they have a marked influence on the over-all tone quality.

**String Supports.**—There must of course be two limiting supports between which a string is made to vibrate. The bridge has already been described. In practice the second "bridge," called the nut, is usually fixed rigidly to the fabric of the instrument beyond the area of the belly. Exceptions to this are the virginals and instruments of the dulcimer family, where both bridges stand on the belly and share the function of transmitting vibrations thereto. The upper extremity of the string is carried over and beyond the nut and there wound upon a peg for tuning. At the other end it is hitched to a string holder or a fixed pin attached to the instrument. Both these terminals are arranged below the level of the bridge and nut to secure a firm down-beating upon them when the string is tightened to its working tension. The bridge, and through it the belly, are then subject to a vertical pressure from the string which ensures sensitivity of response to its vibrations. This pressure bridge is the same type as used on the violin and other bowed instruments, on all keyboard instruments and certain plucked instruments (mandolin, banjo, cittern, etc.).

In keyboard instruments, with their many, carefully graded strings, the bridge is necessarily fixed to the belly, usually by glue. But bridges of the violin type are held in position only by the pull of the strings, thus allowing some latitude for adjusting them to position to get the best result.

A contrast to the pressure bridge is the tension bridge. In this type the strings are attached direct to the bridge unit, which is glued to the belly. The pull of the strings is sustained by the bridge alone instead of by a separate anchorage beyond the bridge. Such bridges are found on instruments of the guitar and lute families, which are characterized by low-lying, rather slack strings and very thin, light bellies. In the harp the strings pull upward, away from the plane of the belly, the bridge being a central rail to which they are pinned.

**Production of Scales.**—The scale of notes that a stringed instrument will give is produced in one of two different ways: either by providing separate strings for every note or by "stopping" a given string somewhere along its working length, thus temporarily

shortening the portion left free to vibrate and raising the pitch of the resultant note. Keyboard instruments, dulcimers and zithers belong to the first class, as also do harps, although for some centuries European harps have employed a limited form of stopping device for the chromatic alteration of some or all of the notes of the scale (see HARP).

In the majority of cases, stopping is accomplished by the player's fingers; he presses the string against a board (the finger-board) that is either raised above the belly as in some forms of zither or, more characteristically, carried on a handle or neck extending beyond the belly to give the hand easier access to the strings. These necked instruments, which always carry the nut and tuning pegs in a head at the upper extremity of the finger-board, exhibit a greater variety of form and size than any other species.

In many instances the fingerboard is fretted; that is, set with a number of raised markers, usually spaced at semitone intervals along the string so that each marker acts as an auxiliary nut when the string is pressed against it. Fretting is not, as is sometimes supposed, merely a guide to correct intonation in the early stages of learning to play the instrument; rather it is an integral part of the tone and technique of those instruments that use it. Among the common western instruments only the members of the violin family are not fretted; in that family the pressure of the fleshy part of the fingertip on a plain fingerboard seems to provide exactly the right kind of stop for a bowed string.

In instruments of the harp kind the many strings have to be graded in length and thickness from the lowest to the highest. None of the developed necked instruments derives the whole of its scale merely from stopping a single string all the way up. All employ several strings of the same length, laid close to each other on the fingerboard so that the same stopping technique may be used on all; but they are graded in thickness and tension in such a way that they may be tuned to widely spaced intervals. The number of strings and their tuning varies with particular instruments, but all have a common purpose: to produce the scale, or large parts of it, by a combination of finger-stopping and crossing from one string to the next above or below, the fingered notes bridging the gap or interval between a string and its neighbours. It is also possible, by stopping and sounding selected notes on different strings simultaneously, to produce chordal effects on such an instrument. Normally, the lowest-tuned string lies to the left of the neck, viewed from the front, and the highest to the right, of those between being arranged in order of pitch. It is customary to refer to the highest-pitched string as no. 1 and to number the others in descending order.

**Methods of Inducing Vibrations.**—Musical strings may be set in vibration by applying energy in a variety of ways, and it is of course the precise method employed, more than anything else, that determines the character of the instrument and the kind of sound it produces. Energy may be applied either by plucking or by striking or by subjecting the string to continuous friction or wind pressure.

**Plucking.**—The first method of inducing vibrations is at once the most primitive and universal. If the string is pulled aside and suddenly released, it will continue vibrating until the initial energy stored by its elasticity is dissipated and it comes to rest. Such a note, consisting of a sharp *ictus* followed by a more or less rapid decay of loudness, does not really "sing," although the ear readily accepts the convention that it does, and both the performer's skill and the maker's craft are directed to sustain the illusion. Moreover, a wide variety of tone colour can be obtained even from a single string by altering the plucking point, or the nature of the material that does the plucking, or the string itself. The player's own fingertips pluck the strings directly in the lutes, guitars and harps and their derivatives, where the strings are mainly of highly elastic catgut and the playing of chords is an everyday occurrence, involving as it does the plucking of several strings at once with different fingers. For many wire-strung instruments, such as the mandolin, a plectrum is used. This is a small lozenge-shaped spatula of hard, flexible material, such as tortoise shell, held in the player's hand and struck across the strings. (For a description of

the keyboard plucking mechanism of the harpsichord see the article HARPSICHORD.)

**Striking** with some form of hammer presupposes that the string shall offer rather more resistance to the blow than strings intended for plucking. Metal strings at comparatively high tension behave best under these conditions and afford the least latitude in the point of striking. What has been said above regarding the *ictus* and decay of the note applies equally here. This system of tone production is not adaptable to instruments with fingerboards, although for completeness it should be said that it has been so applied in one solitary instance, the short-lived English keyed guitar of Christian Clauss (1783). The basic type is rather the dulcimer, a struck version of the older plucked psaltery (*q.v.*). The dulcimer has separate strings (usually duplicated) for every note; the strings are stretched over a flat body or soundboard and are played with hand beaters. This ancient instrument survives in central and east Europe, the Hungarian *cimbalom* and Swiss *hackbrett* being best known. The classic example, however, is of course the pianoforte (*q.v.*) with its elaborate keyboard hammer mechanism.

**Friction or Wind.**—The application of continuous friction to the string in order to obtain sustained sound is the principle of the violin bow. The bow, which also is used with such other instruments as the oriental rebab and the European rebec, consists of a flat ribbon of resined horsehair that is kept under tension by a light, specially curved stick. The bow is drawn across the string at right angles to the string and rather near the bridge. The bow will naturally be designed to suit the weight and size of the instrument, and it is of course used in both directions of travel: downstroke when the hand is moving away from the strings and upstroke when moving towards them. Because of the nature of this technique the player has absolute control over the pressure of the bow on the string, its velocity in traveling across it, and of the exact point at which it is applied to the string. All of these factors are employed to vary not only the attack or articulation by which the note is started but also the loudness or softness and actual quality of the tone produced, and these varieties can, if necessary, be introduced within the duration of a single stroke. In its higher flights the bowed technique is probably capable of a wider range of musical effect than any other form of tone production.

A more mechanical application of the friction principle is that of the medieval *organistrum* or *symphony*, later to become known as the hurdy-gurdy (*q.v.*), in which a resined wheel turned by a handle passes over the strings. Nearly all such instruments, which have never died out at the folk level, have a system of touch-pieces for stopping the strings, as opposed to the direct contact with the player's fingers, and are equipped with "drones" (one-note strings tuned to the prime tones of the piece being played) that form a simple and continuous accompaniment to the tune in bagpipe fashion. The hurdy-gurdy principle has been applied to keyboard instruments many times during the past four centuries but has met no general acceptance.

The final method of eliciting tone from strings is by wind pressure. This is the principle of the Aeolian harp (*q.v.*) and of one or two abortive keyboard instruments where a wind jet directed at the string sets it vibrating. Attractive though the resulting sound is, it is too uncontrollable in attack and duration to have any practical application.

See also SOUND: Strings; the Helmholtz Resonator. (E. HA.)

**STROBOSCOPE**, an instrument that provides a source of periodic, intermittent light. Such devices find common use in the observation of vibrating or rotating mechanical objects. The instrument is usually calibrated to indicate the frequency of vibration or rotation directly, when the rate of light interruption is so adjusted that the observed motion appears to stop. As an instrument for the measurement of speed of rotation, it can be considered a special type of tachometer. Originally a laboratory device, it is now widely used in industry, and in such fields as medicine and psychology.

A single flash of light, if short enough, will produce a motionless image of any moving object. With repetitive light flashes, if the number of flashes per minute is adjusted to correspond

exactly to the number of revolutions per minute (rpm) in the motion, the object will be in the same phase of its rotation whenever it is illuminated and will appear to be stationary. Apparent ultraslow motion will result when the flashing rate and the rate of rotation are slightly different. The apparent motion will be forward if the light-flash rate is slightly less than the rotational rate of the object, backward if it is slightly greater.

Stroboscopic observation depends on persistence of vision on the part of the observer. Below about 50 cycles per second the observer is aware of the intermittent nature of the light, but, in spite of the flicker, he can still follow the action down to about 10 cycles per second. Below this he can see the object illuminated by each flash if the intensity of the flash is sufficient to outshine the continuous light of the surroundings (and if his eyes are focused on the desired spot when the flash occurs).

**History.**—The basic principle of the modern stroboscope is attributed to J. A. F. Plateau (1836). It had been used earlier in a less precise manner by Michael Faraday, and August Töpler (1866) was among the first to reduce the method to an exact science. In the early researches, particularly those concerned with observing acoustical vibrations, two types of procedure were employed. The first made use of intermittent vision; the second employed interrupted light. In both cases a spinning or vibrating disk equipped with a narrow slit allowed a view of the object at periodic intervals of time, or it permitted light to illuminate the body at successive instants. Thus, the object was exposed to view, or was illuminated, at precisely those times when it passed a given point in its motion. A disk device of this sort is called an episcotister.

Research reports and technical literature from the mid-19th century described many types of stroboscopic devices. Plateau's disk with radial slits was used to determine the rotational speed of wheels and shafts. The prongs of a stroboscopic tuning fork were equipped with slotted diaphragms to create periodic interruptions in a beam of light. Rotating and vibrating mirrors were used to produce periodic pulsing of light for stroboscopic observation.

Mechanical-shutter stroboscopes are particularly well adapted for outdoor use in sunlight and are still used. Most stroboscopes for indoor use now employ the method of successive light flashes from an electronic flash lamp, as explained below.

A direct outcome of the early stroboscopic experiments is the modern motion picture. The first motion pictures were a series of hand drawings viewed intermittently through slots that often were a part of the image-rotating system. Moving wagon wheels, when viewed on a motion-picture screen, provide a familiar example of stroboscopic effects. Here the camera shutter serves to produce intermittent vision. If the shutter frequency exceeds that of the successive passages of spokes, the viewer receives a visual impression that the wheels are turning slowly backward.

**Stroboscopic Effects.**—Disks bearing symmetrical patterns are often used to illustrate stroboscopic effects. Two such disks, which show interesting and useful illusions, are shown in fig. 1. Under stroboscopic light the top disk, for example, will show different rows of squares apparently moving in different directions at certain ratios of rotation speed and flashing frequency. Any one row will appear stationary when the following ratio holds:  $F = kR/n$ , where  $R$  is the speed of rotation in rpm,  $F$  is the frequency of the stroboscope in flashes per minute,  $k$  is the number of repetitive patterns such as spokes of a wheel, and  $n$  is any integer such as 1, 2, 3, 4, . . .

A stroboscope can give several readings at which a rotating shaft appears to be stationary. For example, a shaft will seem stationary for one revolution per flash, for two revolutions per flash, and so on, and

FIG. 1.—DISKS THAT SHOW STROBOSCOPIC EFFECTS WHEN ROTATED. (SEE TEXT)

special methods are needed to identify the reading at which speed of rotation  $R$  equals  $F$ .

One method is to increase the rate of flicker slowly, noting the frequencies that show a stationary fundamental pattern. The highest frequency found will correspond to the speed of rotation since this is one flash per revolution. Any higher frequency will leave a multiple pattern on the shaft. For example, if  $F = 2R$  there will be a double pattern on the shaft, since the stroboscope flashes twice per revolution.

Measurement of speeds above the highest frequency of the stroboscope can be calculated by using the multiple-image relationships mentioned above. Assume that the highest frequency of the stroboscope that gives a stationary single pattern is  $F_1$  cycles per second. The next lowest stationary-pattern-producing frequency is  $F_2$ . Since these have a ratio of  $F_1/F_2 = n/n-1$  where  $F_1 = R/n$ , the speed of rotation is  $R = F_1 F_2 / (F_1 - F_2)$  rpm. This method permits the measurement of high-speed repetitive motion with a stroboscope of lower maximum flash speed (or flicker frequency).

**Stroboscope Circuits.**—The modern electronic stroboscope employs a low-voltage gas-filled discharge tube as a lamp to produce a very short flash of brilliant peak light. The lamp is activated intermittently by the discharge of a condenser. Between flashes the condenser voltage builds up stored energy slowly. The instant at which the flash occurs is determined by a grid in the flash tube. An adjustable electronic oscillator furnishes the pulses of grid voltage that control the recurrent discharges in the gas.

A special neon lamp (strobtron) is one type of commonly used gas-filled arc-discharge stroboscope tube (see fig. 2).

FIG. 2.—WIRING DIAGRAM OF A STROBOSCOPIC DEVICE

DC potential of about 350 v. is applied to the discharge condenser (flash capacitor) and to the lamp electrodes a and k. Except when pulsed, a suppressor grid  $g_2$  prevents the discharge of the condenser through the gas. Then an oscillator supplies voltage impulses to a starting grid  $g_1$  at a rate determined by the adjustment of the oscillator frequency. At each impulse the lamp produces a pulse of light that has a duration of about 40 microseconds with a peak intensity of about 50,000 standard candles (see CANDLE POWER).

**Applications.**—The stroboscope has a great variety of applications for precise frequency determinations and for observations of moving parts. A familiar demonstration in the physics laboratory or in the study of musical instruments is the stroboscopic illusion of arresting the motion of a vibrating string to show the number and position of nodes and loops. Thousands of these instruments (fig. 3 shows one called a Strobotac) are in use in research laboratories and in industry. One typical model has a 2-microsecond flash duration and a speed range of 60–25,000 rpm. **Slip-Speed Determinations.**—A common application of the stroboscope is the determination of the so-called slip speed in electrically driven induction motors (see MOTOR, ELECTRIC). The electrical currents in the stationary part of the induction motor

produce magnetic fields that rotate in the air gap and link the windings in the rotating part. This magnetic field rotates at a speed of two poles per cycle of current. For example, a two-pole motor powered by a 60-cycle line will have a field that rotates 60 times per second (3,600 rpm). The speed of the two-pole induction-motor rotor, on the other hand, is less by an amount that depends upon the load. With no load, the rotor speed is very nearly the same as the speed at which the field rotates. As load on the motor is added, the speed decreases. The decrease is called the slip speed and can be measured directly with a stroboscope as follows.

A black circular cardboard disk with a single white spot near the edge is attached to the end of the induction-motor shaft for measuring slip. When the disk is illuminated by a pulsed source operated from the same 60-cycle line, with one flash per cycle, the disk appears to rotate slowly in a backward direction. If, for example, the observer sees one white spot for each pole pair, the spots will be equally spaced. Suppose the rotational frequency of the disk as determined by counting and by the use of a stopwatch is 36 rpm; then the shaft speed of the induction motor is 3,600 minus 36 or 3,564 rpm. The speed of the shaft for a particular motor load can thus be directly compared with the frequency of the alternating current supply, and the slip speed (in this case 36 rpm) is measured directly. The slip is given as a fraction of the slip speed to the synchronous speed; in this case, slip is .01.

**Synchronous-Motor Observations.**—The stroboscope also is most useful for the observation of the synchronous motor, since what is called the power angle can be seen and photographed both in the steady state and in transient conditions. The rotating part of a synchronous motor turns at the same speed (synchronously) as the rotating magnetic field set up by the currents from the line. There is a magnetic field that is stationary with respect to the rotating parts, produced either by a direct current in a winding, by magnetic induction (salient poles), or by permanent magnets. Without load these two fields, one arising from stator currents and the other from rotor currents, line up as a result of forces acting between them. A stroboscope that flashes in phase with the line voltage will show the rotor in a zero phase position in space in alignment with one of the fields. As load is applied, this phase angle (power angle) will increase until the so-called pullout torque is reached; i.e., the motor speed will drop below synchronous speed, and the induction effects will supply the torque. A disk on the shaft marked in degrees permits the power angle to be read directly. Photographs taken with stroboscopic light on a moving film permit the plotting of data that vary so rapidly that they cannot be recorded by a human observer.

**Tachometer for Small Motors.**—The speeds of fractional-horsepower motors cannot be measured by ordinary means, because the load of a conventional tachometer would alter operating conditions. The stroboscopic tachometer, because it requires no mechanical or electrical connection to the motor, is ideal for this use. Speed can be measured under any driving or load conditions (see TACHOMETER).

**Miscellaneous Uses.**—The stroboscope has a wide range of additional applications. The following are typical examples.

1. Electric-motor operation can be studied, particularly as to brush action and vibration.
2. The stroboscope is used in the design of electric fans, particularly to discover sources of vibration. Chemical smokes introduced into the airstream permit study of air currents around blades.
3. Vibration patterns produced by a vacuum cleaner on a rug can be studied.
4. In industrial maintenance work, the operation of gears, cams,

FIG. 3.—COMMERCIAL STROBOSCOPE

and other moving parts can be studied, and misadjustments, misalignment, wear, sources of noise, and so on, can be detected before damage occurs.

5. The reciprocating parts of internal-combustion engines can be studied when a stroboscope is flashed from a contactor on the crankshaft. To study the action of pistons and other enclosed parts a window in the side of an experimental engine is ordinarily used.

6. The stroboscope is used in the textile industry to adjust rotating and reciprocating machines for more efficient operation.

7. In radio manufacturing the stroboscope is used to adjust power-supply vibrators. Both frequency and amplitude of vibration can be studied.

8. The effect of vibration on components intended for aircraft use can be observed under simulated service conditions.

9. In psychology and medicine, stroboscopic devices have been used in the diagnosis of epilepsy (since seizures may be induced by stimulating susceptible people with flickering light). Stroboscopes are also employed in measuring human critical flicker frequency (CFF, also called flicker-fusion frequency; i.e., the stroboscopic frequency at which the flickering light appears continuous to the individual). CFF appears to be related to such factors as the individual's age, degree of introversion, level of fatigue (g.v.), brain-wave characteristics, and the degree of hardening of the arteries in his brain. It has also been reported that CFF gradually increased among U.S. Air Force personnel as they recovered from anxiety neuroses; when the level of anxiety was high, these men tended to perceive flicker only at low frequencies.

**Slow-Speed Stroboscopy.**—Very slow speeds such as those below 600 rpm are quite difficult to measure and observe, since people fail to retain the image during the interval between flashes.

For technical studies at slow speeds, which require a bright light, a more powerful electronic flash can be operated from the stroboscope. This device has been applied, for instance, in the observation of textile looms where the shuttle may make only one or two picks per second. An observer can see the shuttle with a single flash of light, but he must be in a dark environment and must have his eyes directed at the subject when the flash occurs.

**Photography with a Stroboscope.**—The brilliant, short-duration flash produced by the gas-discharge lamp developed for stroboscopic use is admirably suited for photographing rapidly moving objects. Single flashes with durations of one microsecond or less are used in scientific photography, while for ordinary photography flash durations of one millisecond are common. High-speed, single-flash photography is popularly called strobe photography, and the lamps are called strobe lights, although no stroboscopic effect is involved other than stopping motion with a single flash (see PHOTOGRAPHY: Stroboscopic Photography).

With the camera shutter open, a series of exposures resulting from successive flashes of a strobe light can be made. Thus a number of superimposed images on a single sheet of film show various stages of a continuous motion such as a golfer's swing.

See W. G. A. McCormick, "Stroboscopes in Industry," *Industrial Electronics*, vol. 1 (1962). (H. E. Ed.)

**STRODE, WILLIAM** (c. 1599–1645), English parliamentarian, one of the five members of the House of Commons whom Charles I tried to arrest in 1642, was the second son of Sir William Strode, of Newnham, Devon. Educated at the Inner Temple and at Exeter College, Oxford, he represented Bere Alston, in Devon, in every parliament from 1624 to his death. He consistently opposed Charles I and took a leading part in the proceedings in the House of Commons on March 2, 1629, when the speaker, Sir John Finch, was held down in his chair while three resolutions condemning the king's religious policy and the illegal levying of customs duties were carried. Prosecuted before the Star Chamber, Strode refused "to answer anything done in the House of Parliament but in that House." Sentenced to imprisonment during the king's pleasure, he was confined in various prisons for 11 years.

He was liberated in January 1640 at a time when Charles was trying to win support in England for a renewal of the war with the Scots. From this time Strode showed a deeply embittered spirit.

His long imprisonment gave him a reputation, which he might otherwise not have enjoyed, in the party opposed to Charles and his violent speeches and consistent hostility to the government established him among the opposition leaders. In the Long Parliament he proposed parliamentary control over ministerial appointments and the militia, and advocated annual parliaments. He supported the impeachment and trial of Thomas Wentworth, earl of Strafford, and the Grand Remonstrance of November 1641, and when Charles tried to arrest him for treason (January 1642) he was with difficulty persuaded to flee from the House of Commons. Opposing all suggestions of a compromise with the king, he urged on the preparations for war and was present at the Battle of Edgehill (Oct. 23). Bitterly opposed to Archbishop William Laud, on Nov. 28, 1644, he carried the Common's message to the Lords desiring that the ordinance for the archbishop's execution might be hastened.

Strode died at Tottenham, London, on Sept. 9, 1645, and by order of Parliament was buried in Westminster Abbey. His body was disinterred in 1661, following the restoration of Charles II.

(S. R. Br.)

**STROGANOV**, a wealthy Russian family of merchants, probably of Tatar origin, famous for their colonizing activities in the Urals and in Siberia (*q.v.*) in the 16th and 17th centuries. The earliest mention of the family occurs in 15th-century documents that refer to their trading in one of the provinces of Novgorod.

In 1515 Anika (Ioanniki) Stroganov started salt mining in Solvychevodsk; and in 1558 Tsar Ivan IV made a grant of lands along the Kama and Chusovaya rivers to Grigori Stroganov. The Stroganovs were allowed to attract inhabitants to those territories, to build towns, and to maintain their own armed forces for defense, and they were exempted from tax for 20 years. They engaged in salt and iron mining and in the timber and fur trades, and had extensive agricultural interests. They founded the town of Kankor in 1588 and that of Kergedan in 1564. In 1566 Yakov Stroganov petitioned Ivan IV to include the Stroganov estates in the *oprichnina*; i.e., in the crown land administered under the personal control of the tsar. This request was granted in August 1566. A new grant of land in 1568 considerably increased their estates.

The Stroganovs traded with Siberia, but complications in their relations with the khan of Siberia, Kuchum, led to operations of a military nature. They also occasionally had to take arms against the indigenous inhabitants; e.g., in 1572. In 1574 Ivan IV summoned the Stroganovs to discuss plans for the future of Siberia. Two months later they received a grant of land in Siberia along the Tura and Tobol rivers. In 1581 the Stroganovs equipped the expedition of Ermak Timofeevich (*q.v.*), which was to lay the foundation for Russia's annexation of Siberia.

During the Time of Troubles (*see* RUSSIAN HISTORY) the Stroganovs were of great assistance to the second levy raised by Prince D. M. Pozharski and Kuzma Minin, whose activities brought about the accession of Michael Romanov to the tsardom in 1613. The Stroganovs supported Michael's government, paying their taxes in advance and loaning large sums to the empty treasury. They were rewarded by a rise in rank and became answerable for their actions to the tsar alone.

In 1688 Grigori Dimitrievich Stroganov (1650–1715) became the sole owner of all the family's vast estates. He built and equipped two naval vessels for Peter the Great and aided him financially. He was made a baron. In 1798 the emperor Paul I raised Grigori Dimitrievich's heirs to the dignity of count. Throughout the 18th and 19th centuries the family produced statesmen and other men of eminence who continued the tradition of service.

The Stroganovs are also famous for their services to Russian art. Their patronage and commissions resulted in the building of many churches and in the creation of the so-called Stroganov school of icon painting in the 16th and 17th centuries. This school, to which such famous painters as Prokoppii Chirin, Istoma Savin, and the latter's sons Nikofor and Nazari belonged, introduced the techniques of miniature painting as well as rich ornamentation and colouring and an extensive use of gold leaf. (N. An.)

**STROKE** (APOPLEXY) is the term used to describe the combination of signs and symptoms produced by damage to a portion of the brain as result of or in conjunction with at least one of the following four events:

(1) A blood clot forms within a blood vessel of the brain (thrombosis). This is the commonest cause of strokes.

(2) A blood clot lodges in an artery supplying brain tissue after originating in another portion of the body (usually a damaged heart) and traveling to the brain. This is known as an embolism. Both types of clotting reduce or stop the flow of blood to brain cells. During the early stages of apoplexy from these two causes the illness may be further complicated by the oozing of blood and fluid into the surrounding areas (edema).

(3) Intermittent insufficiency of specific arteries results temporarily due to spasm of the arteries or sludging of the blood as it passes through segments of the vessels narrowed by atherosclerosis (arteriosclerosis).

(4) Hemorrhage occurs after an artery ruptures, usually as result of a weakening of the arterial wall due to atherosclerosis or due to a thinning of the wall with bulging (an aneurysm), which may be congenital or develop later in life.

**Consequences.**—The initial onset may be massive in its effect, producing widespread paralysis, inability to speak, coma or death within a short time, usually within several hours or days. On the other hand the onset may be manifested by a series of transient "little strokes" during which the patient may experience weakness and numbness of an arm, leg or the side of his face. There may be temporary difficulty in speech, confusion of thought or visual disturbances. These may recur many times, but eventually they are usually followed by more widespread and permanent paralysis.

The groups of muscles involved are a direct reflection of the artery and brain tissues involved. Most commonly the left side of the brain (dominant side for most persons) is affected, producing paralysis of the right side of the body, because most of the nerves cross to the opposite side of the body from their origin in the brain. However, the combinations of signs and symptoms are innumerable.

Minute strokes may develop as result of closure of many tiny arterioles and produce gradual mental and physical deterioration.

Hemorrhagic strokes are commonly associated with high blood pressure. They frequently produce massive neurological signs, and death is commoner with them than with thrombo-embolic strokes. However, hemorrhagic strokes may be minute and recurrent, gradually producing widespread damage.

**Treatment.**—Precise history and physical examination, especially for neurological changes, are essential to differentiate apoplexy from tumours and brain injury from other causes. It is also important to determine whether the stroke is due to a thrombosis or embolism on the one hand, or hemorrhage on the other. Examination of the spinal fluid for evidence of blood is essential. X-ray studies following the injection of radiopaque substances may clarify the diagnosis. Establishing a differential diagnosis has become essential because anticoagulant drugs are now widely used in the treatment of strokes due to thromboses or emboli but are contraindicated when due to hemorrhage. A stroke may have both a clotting and a significant hemorrhagic factor present, and this presents difficulties.

Many strokes are due to closure of one of the two carotid arteries that supply the brain after passing up the sides of the neck from the aorta. If the closure involves only a small segment, surgery may be attempted to remove the obstruction or to place a graft or bypass using one of the synthetic materials such as Dacron.

Early and persistent efforts for rehabilitation are essential. These should begin within a day or two after the stroke so that muscle tendon contractures will not occur.

For most patients apoplexy or a stroke should not be considered as an isolated disease but as a chapter in the natural history of the over-all condition of atherosclerosis that tends to involve other organs. However, the outlook has been improved by modern treatment.

**STROMNESS**, a small burgh and fishing port on the island of Mainland (Pomona), county of Orkney, Scot. Pop. (1961) 1,479. It is situated on the west side of a well-sheltered bay opening off Hoy Sound. Many of the houses are within tidal limits and are furnished with quays and jetties. The harbour admits vessels of all sizes. There is an egg-packing station, and eggs are exported to the Scottish mainland. The neighbourhood suffered much damage from the great storm of January 1953.

Stromness is a centre for visiting the magnificent scenery of the west coast of Mainland, including Black Craig (400 ft.) and the Hole of Row, a natural arch carved out by the ocean. At the southern edge of the bay of Skail lies the prehistoric village of Skara Brae (*q.v.*).

**STRONTIANITE**, a mineral consisting of strontium carbonate and a principal source of strontium. It takes its name from Strontian in Argyll, Scot., where it appears to have been known as far back as 1764, but it was not recognized as a distinct mineral until later, when the examination of it led to the discovery of the element strontium (*q.v.*). The formula is  $\text{SrCO}_3$ . It crystallizes in the orthorhombic system and is isomorphous with aragonite ( $\text{CaCO}_3$ ) and witherite ( $\text{BaCO}_3$ ). Distinctly developed crystals are of rare occurrence; they are usually acicular with acute pyramidal planes and are repeatedly twinned on the prism. Radiating, fibrous, or granular aggregates are more common. The colour is white, pale green, or yellowish brown. The hardness is 3.5 and the specific gravity 3.7. The mineral occurs in metalliferous veins in the lead mines of Strontian, abundantly in veins in calcareous marl near Münster and Hamm in Westphalia, in limestone near Barstow, San Bernardino County, California, and in geodes at Schoharie, N.Y. It is also found in Washington, Arizona, Texas, and other states.

It is used for producing red fire in highway and railway fuses, marine distress signals and pyrotechny, and for refining sugar.

(CL. F.; X.)

**STRONTIUM**, a metallic element belonging to the alkaline earth family of elements in group two of the periodic table. Strontium (symbol Sr, atomic weight 87.62, atomic number 38) composes about .00019% of the igneous rocks and about .02% of the entire crust of the earth. It is distributed in small quantities in many different rocks and soils. Some is present in bones, in which it replaces small amounts of calcium. Its principal sources are strontianite  $\text{SrCO}_3$  and celestite  $\text{SrSO}_4$ .

William Cruikshank in 1787 first detected the existence of the element in the strontianite found at Strontian in Argyll, Scot. The metal was isolated in 1808 by Sir Humphry Davy, who electrolyzed a mixture of the moist hydroxide or chloride with mercuric oxide, using a mercury cathode. It was obtained in a state of purity by heating the hydride in a vacuum to 1,000° C. It may be obtained in the form of sticks by the contact cathode method, in which a cooled iron rod, acting as a cathode, just touches the surface of a fused mixture of potassium and strontium chlorides and is raised as the strontium collects on it. Because calcium and barium, which it resembles closely, occur in much greater abundance, strontium is not produced in commercially important quantities.

There are four stable isotopes of the element; their mass numbers, in the order of abundance, are 88, 86, 87, and 84. Several radioactive isotopes are produced by nuclear reactions. Of these, the isotope having a mass number of 90 has received most attention because of its presence in the radioactive fallout from nuclear explosions (*see further* **FALLOUT; RADIATION; BIOLOGICAL EFFECTS**). The distribution of electrons in the levels and sub-

levels of the strontium atom is:  $1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 3d^{10}, 4s^2, 4p^6, 5s^2$ .

**Properties.**—Strontium has a silvery white colour. It is malleable and ductile and acts as a good conductor of electricity. Other physical properties are listed below:

Atomic radius .....	2.13 Å
Ionic radius .....	1.13 Å
Ionization potential	
(gaseous element) 1st electron....	5.69 v.
2nd electron....	10.98 v.
Single electrode potential	
(between metal and molar solution of $\text{Sr}^{2+}$ ion) .....	2.89 v.
Melting point .....	$757 \pm 1^\circ \text{C}$
Boiling point .....	$1,366^\circ \text{C}$
Density .....	2.60 g. per $\text{cm}^3$

The chemical properties of strontium are similar to those of calcium and barium, in keeping with its position in the periodic table, where it is above barium and below calcium. Generally speaking, its base-forming characteristics are somewhat less pronounced than those of barium but more pronounced than those of calcium. In its compounds, the element has a valence number of +2. As indicated by its atomic radius, ionization potential and single electrode potential, the atom of strontium easily loses the two electrons in the 5s level when it reacts with nonmetallic elements, thus forming the  $\text{Sr}^{2+}$  ion. The element is an active reducing agent. It reacts readily with water to form hydrogen and the hydroxide  $\text{Sr}(\text{OH})_2$ . It oxidizes rapidly when exposed to the air and burns brilliantly when heated in air, oxygen, chlorine, the vapour of bromine or the vapour of sulphur. With oxygen, the element forms the monoxide  $\text{SrO}$  and the peroxide  $\text{SrO}_2$ .

**Compounds.**—Compounds of strontium are not so extensively used as those of calcium or barium. The solubilities of the salts of the element, generally speaking, are intermediate with respect to the solubilities of the corresponding salts of calcium and barium.

The hydride  $\text{SrH}_2$ , obtained by A. Guntz on heating strontium amalgam in a current of hydrogen, is a white solid that readily decomposes cold water and behaves as a strong reducing agent. The monoxide or strontia  $\text{SrO}$  is formed by strongly heating the nitrate, or commercially from the hydroxide which is produced by heating the sulfide or carbonate in superheated steam (at about 500°–600° C). It is a white powder which resembles lime in its general character. By heating the powder in the electric furnace H. Moissan succeeded in obtaining crystals of the oxide. The compound readily slakes with water and the aqueous solution yields a crystalline hydrated hydroxide. It is used in the extraction of sugar from molasses, since it combines with the sugar to form a soluble saccharate, which is removed and then is decomposed by carbon dioxide. A hydrated peroxide, approximating in composition to  $\text{SrO}_2 \cdot 8\text{H}_2\text{O}$ , is formed as a crystalline precipitate when alkali is added to an aqueous solution of a strontium salt containing hydrogen peroxide. If all the solutions are above 50° C and concentrated, the anhydrous peroxide results.

Strontium fluoride  $\text{SrF}_2$  is obtained by the action of hydrofluoric acid on the carbonate, or by the addition of potassium fluoride to strontium chloride solution. Strontium chloride  $\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$  is obtained by dissolving the carbonate in hydrochloric acid or, commercially, by fusing the carbonate with calcium chloride and extracting the melt with water. It crystallizes in small colourless needles and is easily soluble in water; the concentrated aqueous solution dissolves bromine and iodine readily. By concentrating the aqueous solution between 90° and 130° C or by passing hydrogen chloride into a saturated aqueous solution, a second hydrated form of composition,  $\text{SrCl}_2 \cdot 2\text{H}_2\text{O}$ , corresponding with dihydrated barium and radium chlorides, is obtained. The anhydrous chloride is formed by heating the hydrated chloride in a current of hydrogen chloride.

Strontium sulfide  $\text{SrS}$  is formed when the carbonate is heated to redness in a stream of hydrogen sulfide. It phosphoresces slightly when pure. Strontium sulfate  $\text{SrSO}_4$ , found as the mineral celestite, is formed when sulfuric acid or a soluble sulfate is added to a solution of a strontium salt. It is a colourless solid

that is almost insoluble in water, its solubility diminishing with increasing temperature; it is appreciably soluble in concentrated sulfuric acid. When boiled with alkaline carbonates, it is converted into strontium carbonate.

Strontium nitride  $\text{Sr}_3\text{N}_2$  is formed when strontium amalgam is heated to redness in a stream of nitrogen or by igniting the oxide with magnesium. It is readily decomposed by water, with liberation of ammonia. Strontium nitrate  $\text{Sr}(\text{NO}_3)_2$  is obtained by dissolving the carbonate in dilute nitric acid. It crystallizes from water (in which it is soluble) in monoclinic prisms which approximate in composition to  $\text{Sr}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ . It is used in fireworks (*q.v.*) to produce red colours.

Strontium carbide  $\text{SrC}_2$  is obtained by heating strontium carbonate with carbon in the electric furnace. It resembles calcium carbide, decomposing rapidly with water, giving acetylene. Strontium carbonate  $\text{SrCO}_3$ , found as the mineral strontianite, is formed when a solution of a carbonate is added to one of a strontium salt. It loses carbon dioxide when heated above  $1,250^\circ\text{C}$ .

**Analysis.**—Strontium ion is colourless, almost tasteless, and feebly toxic. Volatile strontium salts impart a carmine colour to the flame. The spectrum of the element is characterized by the two prominent lines corresponding to wavelengths of 422 and 461  $\mu\mu$  ( $10^{-6}$  mm.).

In the usual schemes of analysis, strontium is separated along with calcium, barium, magnesium, and the alkali metals; none of these ions is precipitated by sulfide ion in either an acidic or an alkaline solution.

After precipitation of all other positive ions by the sulfide ion, calcium, strontium, and barium are precipitated as carbonates in the presence of ammonium ion. The precipitate is then dissolved in acetic acid; and, in the usual procedure, barium is then separated by precipitation as the chromate, leaving strontium and calcium ions in solution. Strontium ion can then be separated from calcium by the addition of a dilute solution of sulfate ion which, because of the considerably greater solubility of calcium sulfate, precipitates strontium but not calcium. See also references under "Strontium" in the Index.

Hildebrand, *Reference Book of Inorganic Chemistry*, 3rd ed. (1951); F. Ephraïm, *Inorganic Chemistry*, P. C. L. Thorne and E. R. Roberts (eds.), 4th rev. ed. (1943); A. Engström *et al.*, *Bone and Radiostromium* (1958); F. C. Gran and R. Nicolaysen, *Radio Strontium Deposition in Humans* (1964). (H. T. Br.)

**STROPHANTHUS**, a genus of poisonous plants of the dogbane family (Apocynaceae), comprises about 30 species of woody vines, shrubs, or small trees mainly of tropical Africa but extending into South Africa, with a few species in Asia, from eastern India to the Philippines and China. The genus name, from the Greek meaning "twisted tail," alludes to the long, twisted lobes of the petals, which in some species dangle a foot or more from the flower tube. Although a few species are cultivated for their showy blossoms, the genus is primarily of drug value. Among the few grown for flowers are *S. grandiflorus*, *S. courmontii*, and *S. speciosus*.

The seeds of all species contain biologically active substances used as an arrow poison by some African tribes and as a cardiac stimulant when purified. The chief active principles are glycosides called strophanthins. Strophanthins obtained from various species differ somewhat in chemical structure, and are named according to their source; thus K-strophanthin is obtained from *S. kombe* and G-strophanthin is obtained from *S. gratus*. G-strophanthin, also called ouabain, is an official drug in the British and U.S. pharmacopoeias. It is a pure, crystalline substance, whereas K-strophanthin is an amorphous preparation. The biological activity of both substances is similar, but in K-strophanthin the activity varies according to the composition.

The strophanthins have a digitalislike action on the heart, a property that accounts for their value in the treatment of heart failure (see DIGITALIS). Toxic doses of the strophanthins cause nausea, vomiting and gastrointestinal distress; headache and nervous irritability may precede the gastrointestinal effects. The

heart becomes hyperirritable and ventricular fibrillation and death may result.

*Strophanthus sarmentosus* has been found to be a source of cortisone. (K. P. Du.; X.)

**STROPHE**, a stanza in ancient Greek choral lyric poetry. Some choruses in comedy and satyric drama and a few odes of Pindar consist of the same form of strophe repeated several times. The choruses of tragedy are most often composed in pairs of stanzas of the same metrical pattern, the first stanza of each pair being called the strophe, the second the antistrophe. Most odes of Pindar and Bacchylides are composed in groups of three stanzas: strophe, antistrophe, and epode, the epodes being identical with each other, but different from the strophe and antistrophe. See also ODE. (L. P. E. P.)

**STROSSMAYER, JOSEPH GEORGE** (JOSEF JUMAJ STROSSMAJER) (1815–1905), Croatian Roman Catholic bishop and a leader of the Pan-Slav movement, was born at Esseg in Croatia-Slavonia on Feb. 4, 1815, of German parentage. He became lecturer in theology at Vienna, chaplain to the Austrian emperor and director of the Augustinian body at Rome. In 1850 he was consecrated bishop of Djakovo, with the official title bishop of Bosnia and Sirmium. Strossmayer fostered the growth of Slavonic nationalism in Croatia-Slavonia, in Dalmatia, and among the Slovenes of south Austria, aiding the ban Josip Jelacic (*q.v.*) in his campaigns against Hungary (1848–49) and subsequently becoming a recognized leader of the opposition to Hungarian predominance. (See CROATIA.) Besides being foremost among the founders of the South Slavonic Academy in 1867, and of Agram University in 1874, he helped to reorganize the whole educational system of Dalmatia and Croatia-Slavonia. He built a palace and cathedral at Djakovo, founded a seminary for the Bosnian Croats, presented the South Slavonic academy with a gallery of valuable pictures, and published collections of national songs and tales.

Strossmayer also aided Augustin Theiner, then the librarian at the Vatican, to compile his *Vetera monumenta Slavorum meridionalium historiam illustrantia* (1863). At the first Vatican Council, 1869–70, he was firmly opposed to the definition of papal infallibility. Strossmayer died on April 8, 1905.

**STRUCTURAL ENGINEERING:** see ARCHITECTURAL ENGINEERING.

**STRUENSEE, JOHANN FRIEDRICH**, COUNT VON (1737–1772), German doctor and reforming statesman, who by virtue of the complete control he exercised over King Christian VII was virtual dictator of Denmark from 1770 to 1772, was born at Halle in northern Germany, on Aug. 5, 1737, the son of a Lutheran minister. Educated at Halle University, in the 1760s he became town physician of Altona, then part of Denmark, and through his contacts with Danish courtiers was appointed traveling physician to the mentally unstable Christian VII during his European tour from 1768 to 1769. In 1769 Struensee was made court physician. By January 1770 he was the lover of Christian's queen, Caroline Matilda, and rapidly gained authority in affairs of state. In December 1770 he abolished the council of state and then dismissed the heads of the state departments and abolished the office of *stattholder*, or viceroy, of Norway. In June 1771 he induced the king to appoint him "privy cabinet minister" with supreme authority, and in July was made a count.

Influenced by the French philosophers, and a believer in enlightened despotism, Struensee began a radical reform of law and administration. Between March 1771 and January 1772 he issued more than 1,000 cabinet orders, or more than three a day. He introduced many useful and humane reforms, including the freedom of the press, a reduction in the labour services of serfs, the reform of the municipal government of Copenhagen and the abolition of the harsh penal laws against unmarried mothers. He also abolished the multiplicity of law courts in Denmark and replaced them by a single jurisdiction. However, many of his reforms were insufficiently prepared and were carried out too hurriedly. Opposition to him grew, aggravated by his disregard of national customs (all government decrees and regulations were issued in the German language), the dismissal without compensation of the staffs of public departments, and his affair with the

queen. On Jan. 17, 1772, a conspiracy on behalf of the queen dowager, Juliana Maria, resulted in the arrest of Struensee and his supporters. A commission to interrogate him was set up on Jan. 20, 1772. He defended himself ably, but on Feb. 21 confessed that he was the queen's lover. On April 25 he was sentenced to lose his right hand, then to be beheaded, and his body to be quartered. The sentence was carried out at Copenhagen on April 28, 1772.

**STRUVE, FRIEDRICH GEORG WILHELM VON** (1793-1864), German astronomer, who made a systematic survey of the whole available sky for the discovery and measurement of visual double stars, was born at Altona on April 15, 1793. He attended the University of Dorpat, and was appointed to a professorship of astronomy and mathematics in 1813. He was summoned by Emperor Nicholas I of Russia in 1835 to superintend the building of the Pulkovo Observatory, near St. Petersburg, and became its director in 1839. He died on Nov. 23, 1864.

Struve was a highly skilful observer. The catalog in which his results were published, *Mensurae Micrometricae*, is one of the classics of double-star astronomy. (W. W. M.)

**STRUVE, OTTO** (1897-1963), Russian-born U.S. astronomer who made some of the major astronomical discoveries of the 20th century, was born at Kharkov, on Aug. 12, 1897. A fourth-generation member of a distinguished astronomical family (his great-grandfather was F. G. W. von Struve [q.v.]), he graduated from the University of Kharkov in 1919 and settled in the United States in 1921. He received the Ph.D. degree from The University of Chicago in 1923 and continued as a member of the staff of Yerkes Observatory, where he was director (1932-47). He became a U.S. citizen in 1927. He was director of the Leuschner Observatory of the University of California (1950-59), after which he became director of the National Radio Astronomy Observatory in Green Bank, W.Va. He died in Berkeley, Calif., on April 6, 1963.

Struve occupied a unique place in modern astronomy with respect both to his own discoveries and to the effect he had on other investigators. He was the first to demonstrate that a considerable percentage of stars of high temperature rotate rapidly on their axes. Struve showed that some blue stars have rotation periods as short as a day or less. Perhaps his greatest effect on astronomy was due to work on the nature and distribution of the gas located between the stars. Some of his earlier investigations showed that the interstellar calcium spectral lines strengthen in intensity with increasing distance. Somewhat later he discovered the large-scale distribution of hydrogen between the stars, a discovery that was basic to mid-20th-century advances in radio astronomy and in galactic structure. (W. W. M.)

**STRYCHNINE**, an alkaloid used as a rodent poison and (formerly) in medicine, was discovered in 1818 in Saint-Ignatius's-beans (*Strychnos ignatii*), a woody vine of the Philippines. It also occurs in other species of *Strychnos*, notably *S. nux-vomica*, a tree of India which is the chief commercial source (see *Nux Vomica*). In its natural occurrence strychnine is generally accompanied by brucine (q.v.; dimethoxystrychnine). Strychnine crystallizes from alcohol in colourless prisms, which are practically insoluble in water and soluble with difficulty in the common organic solvents. It has an exceptionally bitter taste. Strychnine is a tertiary monoacid base giving an alkaline reaction.

Strychnine has been used in rodent poisons and in cathartic preparations, and these uses have led to considerable accidental poisoning in children. Suicidal use of the drug has been wide. As a drug, strychnine has no consistently beneficial effect on the cardiovascular system or on the gastrointestinal tract, although in small doses it increases the secretion of gastric juice, excites the motor areas of the spinal cord and increases their reflex irritability, and increases the sensibility of touch, sight, and hearing. Strychnine is partly detoxified in the liver and partly excreted unchanged by the kidneys.

**Strychnine Poisoning.**—Strychnine rapidly enters the blood, whether taken orally or by injection. It acts specifically on the

central nervous system. Symptoms of poisoning usually appear within 20 minutes, starting with stiffness at the back of the neck, twitching of the muscles, and a feeling of impending suffocation. The patient is then seized with violent tetanic convulsions in which the body is arched and the head bent backward. After a minute the muscles relax, and the patient sinks back exhausted, heightened perceptiveness being preserved throughout due to sensory cortex stimulation. A touch, a noise, or some other stimulus causes the convulsions to recur; or they may recur spontaneously, often at intervals of a few minutes. Death from strychnine poisoning is ultimately the result of suffocation or exhaustion.

In treating strychnine poisoning, antidotes such as charcoal or egg white should be administered promptly. Emetics should be avoided as they tend to precipitate convulsions, as does morphine. The patient should be kept quiet and protected from external stimuli. The convulsions can be controlled best by intravenous barbiturates or general anesthesia. Artificial respiration may be necessary.

Sollmann, *A Manual of Pharmacology and Its Applications to Therapeutics and Toxicology*, 8th ed. (1957); H. L. Holmes, "The Strychnos Alkaloids," in R. H. F. Manske and H. L. Holmes (eds.), *The Alkaloids* (1950). (W. J. V.; X.)

**STRYPE, JOHN** (1643-1737), English historian and biographer, whose works are a valuable source for Tudor church history, was born at Houndsditch, London, on Nov. 1, 1643. His uncle, Abraham van Strijp, from Brabant, was a founder of the Spitalfields silk trade, and his father, John van Strijp, was naturalized, and became a freeman of the City. Educated at St. Paul's School (1657-61), Strype entered Jesus College, Cambridge, in 1662, transferring to the more Protestant St. Catharine's Hall in 1663. In 1669, he became curate of Theydon Bois, Essex, but soon moved to Leyton. He was lecturer (i.e., preacher appointed by the Puritans) at Hackney (1689-1724), and died there on Dec. 11, 1737.

A lifelong collector of documents, with a gift for acquiring manuscripts by various means (some not entirely scrupulous), he built up a valuable collection (many of which are in the British Museum). These formed the basis of works which, though often ill-arranged, lacking in literary style, and with innumerable appendices so crammed with documents that they earned him the nickname "Appendix Monger," are of great value to the historian. The most important are his lives of Archbishops Cranmer (2 vol. 1694; ed. by P. E. Barnes, 1853), Parker (3 vol. 1711), and Whitgift (1718); his little volumes on Sir Thomas Smith (1698) and Sir John Cheke (1705), still the best accounts of these paragons of the Indian summer of Edwardian humanism; his *Annals of the Reformation* . . . (4 vol. 1709-31; 3rd ed., with additions, 1735); and his *Ecclesiastical Memorials* . . . (3 vol. 1721, additional vol. 1733). The last two, as collections of primary sources, bridge the gap between those of John Foxe and Gilbert Burnet (qq.v.). Lack of critical sense prevents Strype from being classed as a true historian, but he takes his place among the great chroniclers.

See his *Works*, 19 vol. (1812-24), index, 2 vol. (1828); also S. R. Maitland, *Notes on Strype* (1858). (E. G. RU.)

**STUART, ARABELLA** (ARBELLA STEWART) (1575-1615), first cousin of James VI of Scotland and next after him in the line of succession to Elizabeth I of England, was the daughter of Charles Stewart, earl of Lennox (a grandson of Margaret Tudor by her second marriage) and of Elizabeth Cavendish. To some Englishmen the fact that she was born and bred in England, while her cousin James was Scottish by birth and upbringing, gave her a greater claim to the English throne. She was, therefore, regarded with much suspicion, both by Elizabeth I and by the supporters of James, especially when her name was linked with plots in 1591 and 1597 to prevent his accession. However, when he became king of England as James I, in 1603, Arabella was invited to live at the royal court and was treated with outward respect.

The question of her marriage became a touchy issue. She had

already received numerous marriage proposals, including one from Henry IV of France, but all of these had been vetoed by Elizabeth. The same policy was continued by James, who apparently thought her marriage to any foreign ruler or to any other claimant to the English throne would constitute a threat to himself. Hence, in December 1609, when she attempted to escape from the court to Scotland, probably with the intention of arranging a marriage with an obscure Balkan prince, she was arrested. Brought before the Privy Council (January 1610), she was released and apparently was given an assurance by James that he would not object to her marriage to one of his own subjects. She promptly fell in love with William Seymour (later duke of Somerset), a younger son of Edward, Lord Beauchamp, who also had a claim to the English throne.

When James heard of the romance, he forbade the lovers to marry. The command was disobeyed; on June 22, 1610, Arabella married Seymour at a private ceremony at Greenwich Palace. James's wrath was quickly felt. Seymour was imprisoned on July 8, in the Tower of London, while Arabella was committed to the custody of Sir Thomas Parry at his house at Lambeth. Later, when James learned that the couple were corresponding with one another, Arabella was ordered (March 1611) to be removed to Durham. On her way north she became ill and halted at Barnet, Hertfordshire. She returned to Highgate, near London, and while there made plans to flee to the continent with her husband. Seymour was to escape from the Tower, and they would meet on the coast where a French vessel would take them to Calais. The plan went awry. On June 4, Arabella reached the coast at Leigh in Essex, before Seymour, and at the urgings of her attendants, who feared pursuit, the ship sailed without him. Arriving at Leigh somewhat later, Seymour boarded another vessel which took him safely to Ostend. Arabella was not as fortunate. She was captured in the Straits of Dover, returned to London, and imprisoned in the Tower. Under the strain of imprisonment and separation from her husband, she lost her reason and finally died on Sept. 25 or 27, 1615. She was buried in Westminster Abbey.

See P. M. Handover, *Arabella Stuart* (1957).

(R. C. Jo.)

**STUART, GILBERT CHARLES** (1755–1828), U.S. painter, one of the great portraitists of his era and the creator of the most popular image of George Washington, was born on Dec. 3, 1755, in his father's snuff mill near Narragansett, R.I. He grew up in nearby Newport and there learned the rudiments of painting from Samuel King and Cosmo Alexander, a visiting Scotsman. He accompanied Alexander to Edinburgh about 1771, but returned home a year later. In 1775 he went to London and entered the studio of Benjamin West, with whom he worked for about six years. His mature style owed more, however, to Thomas Gainsborough and Sir Joshua Reynolds than to West. In 1782 he opened his own London studio and for five years enjoyed great success, but in 1787 he fled to Dublin to escape his creditors. After six years in Ireland he returned to the U.S. in 1793, worked for a year in New York, then settled in Philadelphia, then the political and cultural capital of the nation. He quickly established himself as the nation's leading portrait painter, a position he held until his death on July 9, 1828, in Boston, where he had settled in 1805.

Stuart's work was hailed by his contemporaries and subsequent critics have confirmed this judgment, especially praising its painterly brushwork, luminous colour, and psychological penetration. Of his nearly 1,000 portraits, undoubtedly the most famous is the unfinished head of George Washington (1796) at the Boston Athenaeum. (For a reproduction of this work see WASHINGTON, GEORGE.) Other fine portraits are those of Mrs. Richard Yates and "The Skater," both at the National Gallery, Washington; Mrs. Perez Morton, Worcester (Mass.) Art Museum; and John Adams, privately owned.

Although Stuart had no formal pupils, many young artists, including John Vanderlyn, Thomas Sully and John Neagle, availed themselves of the advice he freely gave. Less talented artists, including his own daughter Jane, simply reduced his style to a formula which gave a Stuartesque appearance to much U.S. portraiture of the succeeding generation.

**BIBLIOGRAPHY.**—William T. Whitley, *Gilbert Stuart* (1932); Lawrence Park, *Gilbert Stuart: an Illustrated Descriptive List of His Works* (1926); William Sawitsky, "Some Unrecorded Portraits by Gilbert Stuart," *Art in America* (1932); James Thomas Flexner, *Gilbert Stuart* (1955). (D. H. W.)

**STUART, JAMES EWELL BROWN** ("JEB") (1833–1864), Confederate cavalry officer in the American Civil War, was born in Virginia on Feb. 6, 1833, and entered the U.S. Military Academy in 1850. When Virginia seceded from the Union, Stuart resigned his commission in the United States Army to share in the defense of his state. At the First Battle of Bull Run (1861) he distinguished himself by his personal bravery. Later in the year he was promoted brigadier general and placed in command of the cavalry brigade of the Army of Northern Virginia. Just before the Seven Days' Battle he was sent out by Lee to locate the right flank of McClellan's army; he not only successfully achieved his mission but rode completely around McClellan's army to deliver his report to Lee at Richmond. In the next campaign he had the good fortune, in his raid against General Pope's communications, not only to burn a great quantity of supplies but also to bring back a staff document from which Lee was able to discover the strength and position of the Union forces. Stuart, now a major general and commander of the cavalry corps, was present at the Second Battle of Bull Run (1862), and during the Maryland campaign he brilliantly defended one of the passes of South Mountain (Crampton's Gap), thus enabling Lee to concentrate his army in time to meet McClellan's attack. At Fredericksburg Stuart's horse artillery rendered valuable service in checking Franklin's attack on "Stonewall" Jackson's corps. At Chancellorsville Stuart was appointed by Lee to take command of the 2nd Army Corps after Jackson had been wounded. The next campaign, Gettysburg (1863), was preceded by the cavalry Battle of Brandy Station, in which for the first time the Federal cavalry showed themselves worthy opponents for Stuart and his men. The Confederates' march to the Potomac was screened by the cavalry corps, which held the various approaches on the right flank of the army, but at the crisis of the campaign Stuart was absent on a raid. He attempted to rejoin Lee during the battle, but was checked some miles from the field. Shortly after the opening of the campaign of 1864 Stuart's corps was drawn away from Lee's army by the Union cavalry under Sheridan; part of it was defeated at Yellow Tavern on May 11, and Stuart himself was wounded and died on May 12.

See J. W. Thomason, *Jeb Stuart* (1930).

**STUBBS, PHILIP** (c. 1555–c. 1610), English Puritan and pamphleteer. He seems to have spent some time at Cambridge but left without a degree. In 1586 he married Katherine Emmes, then aged 16, who about four years later died in childbirth. To judge from his biographical account of her, *A Cristall Glasse for Christian Women* (1591) she was a more bigoted and narrow Puritan even than himself; on her deathbed she edified him by declaring her affection for a puppy to have been sinful vanity. However, Stubbs had probably recreated her in his own image. The chief works of this vigorous propagandist for a purer life and stricter devotion were *The Anatomie of Abuses* (1583), *A Rosarie of Christian Prayers and Meditations* (1583), *The Theatre of the Pope's Monarchie* (1584), *A Perfect Pathway to Felicitie* (1592), and *A Motive to Good Workes* (1593). The *Anatomie* proved the most popular of his books, probably because it consisted of a devastating attack on English habits in dress, food, drink, games, and especially sex. To do Stubbs justice, his outpourings on the subject of "whoredom" arose less from prurient than from genuine distress. At first inclined to condemn only excessive concentration on all these worldly pastimes, he eliminated such weakness from later editions and denounced all forms of them. As a writer he was third rate, his matter conventional, and his manner mainly pompous: it passes understanding how some scholars could ever have charged him with having had a part in the humorous and satire of the Marprelate tracts. (G. R. E.)

**STUBBS, WILLIAM** (1825–1901), English historian, bishop of Oxford from 1888 to 1901, was founder of the systematic study of English medieval constitutional history, and his influence even where unacknowledged or criticized, continues to pervade

most works on this subject. Born at Knaresborough, Yorkshire, on June 21, 1825, the son of a solicitor, he went up to Christ Church, Oxford, as a servitor, graduating (1848) with a first class in classics and a third in mathematics. Elected a fellow of Trinity College (1848), he was ordained priest (1850) and held the college living of Navestock, Essex, from 1850 to 1866. In 1862 he was appointed librarian at Lambeth Palace, and in 1866 regius professor of modern history at Oxford. Consecrated bishop of Chester (1884), he was translated to Oxford in 1888. He died at Cuddesdon, near Oxford, on April 22, 1901.

Stubbs's first publication was *Registrum sacrum anglicanum* (1858; rev. ed. 1897), tables of the successive holders of English bishoprics; later he joined A. W. Haddan in editing *Councils and Ecclesiastical Documents Relating to Great Britain and Ireland* (1869-73). His *Select Charters . . . From the Earliest Times to the Reign of Edward the First* (1866; 9th ed., rev. by H. W. C. Davis, 1913) was soon established as a textbook, and, revised, remains in use. Stubbs's contemporary fame, however, rested primarily on *The Constitutional History of England in its Origin and Development*, 3 vol. (1873-78; French trans., 1907), which reached a wide audience. This work, which traces the development of English institutions from the Teutonic invasions of Britain till 1485, is now much criticized, and Stubbs's best work is held to lie in the 19 volumes of editions of medieval English chronicles which, between 1864 and 1889, he contributed to the Rolls Series.

Stubbs's output was immense, and this prolixity caused many of the faults with which he has been charged. He consulted only printed sources, and sometimes, lacking sufficient evidence, reached erroneous conclusions. As an editor, he did not always adequately investigate the derivation and authority of his sources. Some critics accuse him of preconceived prejudice, as reflected in his appendix to the report of the Royal Commission on Ecclesiastical Courts, on which he served (1881-83); his arguments on medieval English Canon Law there expounded were compellingly refuted in 1896 by F. W. Maitland, normally an admirer of Stubbs. Nevertheless, whether progress in English constitutional studies derives from following or from reacting against Stubbs's views, it is still impossible to neglect them.

Maitland, "William Stubbs, Bishop of Oxford," *English Historical Review*, vol. xvi (1901), reprinted in Maitland's *Collected Papers*, vol. iii (1911); J. G. Edwards, *William Stubbs* (1952); H. Cam, "Stubbs Seventy Years After," *Cambridge Historical Journal*, vol. ix, no. ii (1948); H. G. Richardson and G. O. Sayles, *The Governance of Mediaeval England* (1963).

**STUCLEY (STUKELY), THOMAS** (c. 1525-1578), English soldier of fortune and buccaneer, chiefly remembered for his intrigues to promote an invasion of Ireland during the reign of Elizabeth I, was the third son of Sir Hugh Stucley of Affeton, near Ilfracombe, Devon. Before 1551 he entered the service of Edward Seymour, duke of Somerset, and on the latter's fall from power in that year, Stucley fled to France and served in the army of Henry II against the emperor Charles V. In August 1552 he appeared at the court of Edward VI with a letter of recommendation from Henry II and on Sept. 16, 1552, he revealed French plans for an invasion of England. He was imprisoned in the Tower of London while further investigations were made. Released in August 1553 shortly after the accession of Mary I, he went to Brussels and served in the Imperial Army under Emmanuel Philibert, duke of Savoy. In December 1554 he returned to England and, heavily in debt, married Anne Curtis, heiress of a wealthy merchant. In May 1555 his arrest was ordered for counterfeiting money, but he escaped abroad and fought under Savoy against the French at the Battle of Saint-Quentin (August 1557).

His wife inherited her fortune in November 1559, but Stucley's debts soon grew and in June 1563 he set out on an expedition authorized by Elizabeth I to colonize Florida, though this was almost certainly only a pretext to engage in buccaneering. Stucley's captures of French, Spanish, and Portuguese ships made his name notorious abroad, and in 1565 Elizabeth was forced to take note of complaints and have him arrested, but the charge was not proceeded with. For most of the period from 1565 to 1570 Stucley was in Ireland, where Elizabeth twice forced him to re-

nounce offices and estates which he had bought. For some time he had been in secret contact with Philip II of Spain, and in April 1570 he went to Spain. But his schemes for a Spanish invasion of Ireland were not acted upon and Philip sent him to Sicily, where he commanded three galleys under Don John of Austria at the Battle of Lepanto (October 1571). Returning to Spain in 1572, Stucley again failed to get support from Philip for an invasion of Ireland, and in 1577 he turned instead to Pope Gregory XIII. Leaving Civitavecchia, near Rome, for Ireland, in March 1578 with an ill-fitted galleon and 600 men he was forced to put in at Lisbon. There King Sebastian persuaded him to join his expedition against the Moors in Morocco. Stucley was killed at the Battle of Alcazarquivir on Aug. 4, 1578.

See R. Simpson, *The School of Shakspeare*, vol. 1 (1878), which contains a biography of Stucley.

**STUDEBAKER**, the family name of five brothers associated in the manufacture of wagons, carriages, and automobiles in the United States. CLEMENT STUDEBAKER (1831-1901) was born in Pinetown, Pa., March 12, 1831, and worked in his father's blacksmith shop in Ashland, O. In 1850 he moved to South Bend, Ind., to work as a schoolteacher, and there, two years later, with his older brother, HENRY STUDEBAKER (1826-95), he founded the firm of H. & C. Studebaker, blacksmiths and wagonmakers. In 1858 another brother, JOHN MOHLER STUDEBAKER (1833-1917), bought out Henry. The Civil War provided the firm with a large government contract, and in 1868 the company was incorporated as the Studebaker Brothers Manufacturing Co., at which time another brother, PETER EVERST STUDEBAKER (1836-97), joined the firm. A fifth brother, JACOB FRANKLIN STUDEBAKER (1844-87), joined the firm in 1870, the year in which the company opened its first branch office at St. Joseph, Mo., to outfit settlers moving West. At that time the firm was the largest manufacturer of horse-drawn vehicles in the world, and during its entire history it produced more than 750,000 wagons. With the advent of the automobile the firm began experiments in its manufacture in 1897. Soon after Clement's death, the firm started building electric (1902) and gasoline (1904) automobiles. Clement was succeeded as president by John. In 1911 the firm was absorbed by the Studebaker Corp., and in 1954 the Studebaker Corp. merged with the Packard Motor Car Co. Automobile production in South Bend ceased in 1963, though it continued on a reduced scale at the Studebaker plant in Hamilton, Ont.

See also SOUTH BEND; AUTOMOTIVE INDUSTRY. (W. H. D.)

**STUDENT AID** is an award, loan, or other form of assistance designed to help students obtain a higher education, usually at a college or university. In general, such awards are known as scholarships, fellowships, or loans; in European usage, a small scholarship is an exhibition, and a bursary is a sum granted to a needy student. Many awards are in the nature of long-term loans with low rates of interest. In a large number of countries student aid takes the form of government subsidies to reduce or eliminate tuition, room, board, and other fees and expenses. On most U.S. campuses, student employment services provide opportunities for students, especially men, to help pay their own way through part-time employment.

In Great Britain and on the continent, where colleges and universities are considerably older than those in the United States, marked differences appear in aims, traditions, and historical factors. In most countries student aids follow the pattern set in the United States or in Great Britain. The English educational system, with its medieval traditions, sought to provide grammar school facilities (secondary education) for only a small proportion of the population (see SECONDARY EDUCATION). University education was intended for a still smaller proportion, and until the 20th century relatively few students were selected by real or supposed merit. So the characteristic feature of the English system has been the scholarship, often quite generous in amount, but available only to the few after a fiercely competitive examination. (See EDUCATION, HISTORY OF; UNIVERSITY.) Despite vast increase in university and college provision in the United Kingdom, especially after World War II, the proportion of U.S. citizens taking full-time higher education was still much greater.

**Growing Needs.**—The growth of higher education throughout the world has constituted one of the major social revolutions of recent times. Nations with already well-developed systems of higher education have expanded them in response to growing student populations and demands to broaden higher educational opportunities. For example, the number of students enrolled in U.S. colleges and universities jumped from 2,250,000 in 1950 to approximately 4,500,000 by the 1960s; the number of university students in the Soviet Union more than doubled, rising from 1,250,000 to almost 3,000,000; French university enrollment increased from 150,000 to almost 250,000; and the number of Japanese students rose from approximately 400,000 to more than 700,000.

Developing nations, many newly independent, have also given high priority to the creation of college and university facilities. University enrollment in India, for example, soared from 425,000 in 1950 to almost 1,000,000 by the 1960s. Increases of even greater proportions have occurred in some newer countries where the student population, although still minuscule, has grown at an astronomical rate. Senegal, for example, which had only 250 university students in 1952, had ten times as many in the 1960s. In all, the world's university student population of about 14,000,000 more than doubled within the decade after 1950.

This striking growth in higher education has been in great part fostered by programs of scholarships, fellowships, loans, and other forms of financial assistance to students. These are provided by governments and academic institutions; business, industry, and labour organizations; foundations; religious, civic, and fraternal groups, and other private organizations; and by individuals. As a result of these financial aid programs, opportunities for higher education, once the prerogative of the economic and social elite in many lands, have become increasingly available to students who would otherwise be denied the opportunity. Indeed, although reliable statistics are not always available, it is clear that college and university students receiving some form of private or public support constitute in all countries an important, and in some countries an overwhelming, proportion of the university enrollment.

**Government Programs.**—In the great majority of countries, tuition at institutions of higher learning is either free or nominal. Generally, higher education is under the auspices of a government ministry, and although institutions jealously guard their academic autonomy, they are either directly or indirectly financed by government funds. Higher education is free in the Soviet Union and other Eastern European countries, the Scandinavian countries, the Republic of China (Formosa), and the People's Republic of China, to name only some. Tuition is either free or nominal throughout Latin America, and in most European, Asian, and Middle Eastern countries it is nominal. Even where tuition charges are appreciable, as in Great Britain, an extensive scholarship program supported by both government and the universities effectively underwrites this cost for most students. Students are also assisted to meet costs other than tuition, particularly living expenses, through stipends, loans, grants, and other financial aid.

In Austria and Japan about a quarter of the students receive government financial aid; in Denmark and Norway, more than half; and in the United Kingdom 90%. State aid for French students is very comprehensive. Indirect aid includes subsidies to students' quarters and student restaurants (half the cost of meals); contributions to students' social insurance; and the building of student hostels and restaurants. In the Federal Republic of Germany, about 30% of German university students receive aid from public funds. In Hungary, more than 60% of the students receive scholarships: government assistance includes provision of hostel accommodation (for about 50% of the total); and reduced-price meals (for 30%). Among the provisions for student aid in India is the Union Education Ministry's national loan scholarship scheme for future teachers. More than 18,000 of these loans are made annually to needy students following full-time courses of higher education or training. They vary in amount according to the course, a supplement being arranged for students following engineering and similar courses: repayment is called for at the rate of 10% a year.

Statistics on the number of U.S. students receiving government financial assistance are difficult to obtain, but it is estimated that on the graduate level alone, more than 70,000 fellowships and research assistantships are awarded annually.

Although the number of U.S. students receiving financial assistance from the government is proportionately less than in other countries, the scope of the U.S. government's support program nonetheless has become massive. Among the major scholarship programs financed by federal funds are those of the National Science Foundation, which annually disburses more than \$30,000,000 to accelerate the training of promising students in science, mathematics, and engineering; the National Aeronautics and Space Administration, which disburses a somewhat smaller sum for fellowships in flight training, aeronautics, and special research; and the National Institutes of Health, whose grant program approaches \$50,000,000 annually to support study in various fields of medicine and public health. More modest sums are provided by the Atomic Energy Commission and the Department of Health, Education, and Welfare to encourage competence in such fields as nuclear science and engineering mechanics, biology and medicine, vocational rehabilitation, and the teaching of the retarded. Less restricted as to field are the grants offered under the National Defense Education Act, which amount to more than \$20,000,000 a year in scholarships and fellowships to increase the number of university teachers in all fields, but especially in modern languages, science, and international affairs. A student planning to teach may borrow up to \$2,500 per year; and if he enters teaching after completing the program, up to 50% (10% per year up to five years) of the loan is forgiven. In all, the federal government appropriates more than \$120,000,000 a year to support college and university study.

**College and University Aids.**—U.S. colleges and universities provide financial assistance in an amount at least equal to, if not greater than, that provided by the federal government. In some state and municipal institutions, tuition is free to students who are legal residents and some scholarships are provided by state governments. In the 1960s, U.S. academic institutions granted an estimated 320,000 scholarships and fellowships a year, more than twice as many as a decade earlier. The dollar value of these awards is estimated to be well in excess of \$100,000,000. These grants, usually but not always provided to students of high ability without adequate financial resources, range from a mere reduction of tuition fees to grants covering all fees, tuition, and living expenses. Frequently, the recipient of a college or university grant is required to provide some service to the institution. An undergraduate may work as a clerk in a library or as a waiter in an eating hall, for example, and a graduate student may assist a professor in a laboratory. This arrangement is almost unique to the United States.

**Private Foundations and Corporations.**—Although corporations, foundations, religious, civic, and other groups provide funds for the support of students in many countries, and especially in Europe, nowhere does their involvement equal that in the United States. Led by the Ford, Rockefeller, Carnegie, Guggenheim and Danforth foundations, U.S. philanthropic foundations contribute more than \$50,000,000 annually to fellowships, scholarships, loans, and other programs of student aid. The Woodrow Wilson National Fellowship Foundation maintains the largest private program, offering 1,000 awards every year to future college teachers of the liberal arts. U.S. corporations, too, have taken an increasingly active interest in this form of philanthropy. Their contributions to student aid programs are estimated to be well over \$30,000,000 a year.

The National Merit Scholarships Corporation (NMSC), a nonprofit organization, was established in the United States in 1955 through a \$20,000,000 grant from the Ford Foundation and a \$500,000 grant from the Carnegie Corporation of New York to operate a coordinated, nationwide scholarship program. Scholarships financed through the Ford Foundation grant are known as National Merit Scholarships; those provided by business corporations, foundations, unions, etc., usually bear the name of the sponsor—e.g., Sears-Roebuck Foundation Merit Scholarships. More than 1,600 awards are granted each year on the basis of competitive

examinations and school records; individual amounts depend on financial need.

Similar student aid programs are sponsored by other private organizations, including churches, foundations, unions, industries, trade and professional associations, fraternal groups, and clubs.

**International Exchange Scholarships.**—An especially significant development in the second half of the 20th century has been the growth of programs of international education, or the exchange of persons between nations for educational purposes. From the wandering scholar of classical times to the Fulbright fellow and the Rhodes scholar of the 20th century, men have ignored national boundaries in their search for knowledge. But it is only in recent years that educational exchange has enjoyed the interest and active support of governments, academic institutions, and other elements of society. As a result, educational exchange has added a new dimension to higher education, and to the conduct of foreign relations. This development has been in part a response to the need for education in emerging countries unable to provide training for their own people, and in part due to the hope, if not the conviction, that the exchange of students, scholars, artists, and others concerned with education in particular and culture in general contributes to international understanding and peace.

The dimensions of educational exchange may be suggested by the fact that by the 1960s there were approximately 250,000 students annually studying at institutions of higher learning in countries other than their own. To this number must be added thousands of scholars teaching and engaged in research at foreign institutions, as well as thousands of other individuals traveling abroad on short-term educational and cultural assignments. The United States, which has replaced Europe as the mecca of the exchange student, in the 1960s was host to more than 80,000 foreign students a year, about one out of every four exchange students, and twice as many as had been there a decade earlier.

Students participating in educational exchange are the beneficiaries of a wide and growing range of financial grants. Fully two-thirds of the foreign students in the United States receive support from one or more sources, including the United States or their own government, a college or university, or a foundation, corporation, or other private organization. Internationally, there are approximately 130,000 individual opportunities each year for subsidized international study and travel offered by more than 1,600 donor agencies in over 100 states and territories.

Because international education is considered an important factor in international relations, governments have played an especially important role in supporting it. Probably the best known government program is that of the United States, popularly known as the Fulbright program (after Sen. J. William Fulbright of Arkansas, who conceived it). The Fulbright Act of 1946 and subsequent legislation concerning educational exchange were consolidated and expanded in the Mutual Educational and Cultural Exchange Act of 1961, known as the Fulbright-Hays Act. The purpose of these programs is to increase mutual understanding between the people of the United States and the people of other countries by means of educational and cultural exchange. In less than 20 years, the Fulbright Program enabled more than 26,000 Americans to study abroad and brought almost twice that many foreign citizens to the United States at an expenditure of \$330,000,000. The largest proportion of these 75,000 exchangees were students. But the Fulbright program also includes other categories: elementary and secondary school teachers; college and university professors and advanced researchers; and trainees and observers.

During one fiscal year, grants were issued to more than 5,000 citizens of 130 countries and territories allowing them to come to the United States for the following purposes: over 2,000 for university study, about 750 to lecture or conduct postdoctoral research at institutions of higher learning, 800 for observation and consultation, 850 to teach in elementary or secondary schools or for specialized training, 700 for special educational travel, and 650 for advanced training and practical experience in specialized and technical fields.

During the same period, 2,500 U.S. citizens were awarded grants to go abroad: 900 for graduate study, 700 to lecture or conduct postdoctoral research at institutions of higher learning, 600 to teach in elementary or secondary schools, or to attend foreign language summer seminars, and 300 for general lecturing or specialized consultation and advice.

All these categories of the exchange programs are administered by the Board of Foreign Scholarships, Bureau of Educational and Cultural Affairs, Department of State. A number of public and private agencies assist in administering the program. The Institute of International Education is responsible for the preliminary selection of U.S. student grantees and the placement and supervision of foreign student grantees. The elementary and secondary teacher program is under the supervision of the Teacher Exchange Section, Division of International Education, Office of Education. The Conference Board of Associated Research Councils is responsible for the program for university teachers and postdoctoral research candidates.

In more than 40 countries that have signed executive agreements with the United States on educational and cultural exchange, binational commissions or foundations have been established to assist in the administration of the program abroad. In other countries this activity is the responsibility of the United States Embassy.

Foreign student candidates for Fulbright grants, which are unrestricted as to field of study, must have a Bachelor of Arts degree or its equivalent and be under 35 years of age. There are two types of awards. A limited number provide round-trip transportation only. These must be supplemented by a scholarship or a fellowship from a college, private organization or other agency, or by the candidate's own funds.

As a rule, the U.S. candidate for a Fulbright grant must have a Bachelor of Arts degree or its equivalent, although if he is in the creative and performing arts, four years of professional study or experience will be accepted in lieu of a degree. Proficiency in the language of the country in which he plans to study, general maturity, scholastic competence, and the ability to promote the basic objectives of the Fulbright program are other qualifications. Preference is given to candidates between the ages of 20 and 35. The grants range from awards to cover round-trip transportation to awards covering all expenses, including transportation, tuition, books, maintenance, and insurance.

Among the private programs in international education are those sponsored by the Guggenheim Foundation, the Rotary International, the American Association of University Women, the International Association of Students in the Economic and Commercial Sciences, and, perhaps the most prestigious of all, the Rhodes Fellowship trusts.

Rhodes scholarships, established by Cecil John Rhodes (*q.v.*) in his will, have as their purpose the promotion of unity among the English-speaking peoples of the world. The scholarships are offered to male citizens of the British Commonwealth and colonies, the Republic of South Africa, and the United States, who are between the ages of 19 and 25, of high ability and character, and who are likely to use their talents in public service. (In the periods 1903-16 and 1930-39, the awards were also offered to citizens of Germany.) In the 1960s, 70 scholarships were awarded annually, 32 of them to United States citizens, by far the largest number assigned to any one country. The scholarships are tenable for two or three years at Oxford University and carry a stipend of £900. A Rhodes scholar may marry after his first year of residence at Oxford.

Other nations also support exchange programs for their own and foreign students. An estimated 10,000 students from developing countries and several thousand more from neighbouring Communist countries are studying under scholarships in the Soviet Union. A great majority of the more than 60,000 foreign students in Great Britain are indirectly subsidized by government funds, while all 30,000 foreign students in France receive free tuition, subsidized meals, social security services, and other benefits.

In Austria, the Minister for Education grants about 170 annual scholarships and about 50 summer scholarships for language

courses, for which foreign students, including new graduates, are eligible, some of them under exchange schemes. Denmark offers eight-month exchange scholarships including contributions to travel expenses, to both graduate and undergraduate students of 13 Western European countries, including the United Kingdom, France, and the Federal Republic of Germany, and to nationals of the U.S.S.R., Czechoslovakia, Yugoslavia, Poland, Turkey, Japan, and the United States; scholarships for postgraduate study are offered to nationals of Belgium, Czechoslovakia, Italy, Poland, the U.S.S.R., and the United States; and about 235 unilateral scholarships of varying periods of tenure are offered to students from the developing countries.

The Federal Republic of Germany has many scholarship programs, both public and private, for foreign university students. The Deutsche Akademische Austauschdienst (German Centre for Academic Exchanges) awards more than 2,000 such scholarships and organizes exchanges of students in engineering, natural sciences, medicine, and occasionally in agriculture and political economy. The individual German *Länder* also offer scholarships; and a total of several hundred is awarded by Roman Catholic and Protestant institutions, by the Friedrich Ebert Foundation, and by the German associations of student unions. Exchange programs with foreign universities are founded partly on sponsorship and other links. Scholarships and exchange programs for foreign students are open to nationals of most countries of the world. In the 1960s about a quarter of the foreign scholarship holders came from Europe, and the remainder from the Far East, Latin America, Africa, the Near East, North America, and Australia. In Hungary, about 200 foreign students are granted scholarships each year by the government on the basis of cultural and other agreements with countries of Africa, Asia, and Latin America. The government of India awards each year nearly 500 scholarships and fellowships to students of certain Asian, African, European, and other countries. There are scholarship exchanges, under cultural exchange agreements, with a number of countries including Bulgaria, Greece, Poland, Rumania, Yugoslavia, the U.S.S.R., and the United Arab Republic. Other reciprocal scholarship schemes exist with other countries of Europe and South America. Under the Commonwealth Education Co-operation scheme, the government awards scholarships, fellowships, and bursaries to nationals of Commonwealth countries, some of them for postgraduate study, others for teacher training, for study or observation by senior educationists, and for the training of craft instructors. The awards vary in duration from three months to two years; those for craft instructors are open only to nationals of those Commonwealth countries not included in the educational exchange program conducted under the Colombo Plan.

**International Organization.**—International agencies, naturally, play a major role in supporting international studies. Such specialized agencies of the United Nations as the Food and Agriculture Organization, the World Health Organization, the United Nations Educational, Scientific, and Cultural Organization, and the International Atomic Energy Agency employ exchange programs to encourage proficiency in specialized fields and to assist the development of emerging countries. The fellowship awards are usually made to experienced individuals whose work in areas important to their home countries will be benefited by specialized training or study. The awards are granted for work in any country in which study or training may be effectively pursued. The grants usually include round-trip transportation, tuition, books, and a monthly maintenance allowance which varies according to the country to which the grantee is assigned.

Among the major agencies sponsoring such fellowships is the Food and Agriculture Organization, which provides grants to enable scientists and technicians from less developed countries to advance their training in various aspects of nutrition, agriculture, forestry, and other related fields. The World Health Organization maintains one of the largest fellowship programs, designed to improve standards of health and the level of teaching and training in countries throughout the world. It awards fellowships in public health, nursing, sanitation, child care, and related medical fields. The fellowship program of the International Atomic Energy

Agency is one of the smallest but most highly specialized, concerned with such subjects as the development and use of nuclear energy for peaceful purposes and the theoretical and experimental aspects of the science and technology of nuclear energy.

Contrasted to the highly specialized program of the International Atomic Energy Agency is the United Nations Educational, Scientific, and Cultural Organization's program, which sponsors a broad fellowship program in the field of education, social science, cultural activities, mass communications, and the mutual appreciation of Western and non-Western cultural values. More than 2,000 persons a year are beneficiaries of UNESCO fellowships. In all, the various intergovernmental agencies of UNESCO provided more than 30,000 fellowships to nationals of developing countries by the 1960s.

Another major source of sponsorship of international educational programs is regional organizations, whose interest in underwriting such programs is, as in the case of UN agencies, to assist economic development and encourage international understanding. Since 1958 the Organization of American States has awarded up to 500 fellowships a year to candidates from member nations to allow study for between three months and two years in any other member country and in any field representing a basic need of their home country. These grants cover, at the maximum, tuition, maintenance, and transportation.

Similar in purpose to the OAS fellowship program, though far more modest in scope, are the programs sponsored by such regional organizations as the Southeast Asia Treaty Organization, the Organization for Economic Cooperation and Development, and the Colombo Plan. (G. K. H.)

II, *For U.S. Nationals* (1965); UNESCO, *Study Abroad* (biennial); S. N. Feingold, *Scholarships, Fellowships and Loans*, vol. I–IV (1949–62), with bibliography; university and college calendars, or catalogues, announcements, bulletins, etc., usually issued annually; publications of the U.S. Department of Health, Education, and Welfare, Office of Education; *Commonwealth Universities Yearbook* (annual); *Higher Education in the United Kingdom* (biennial). (W. J. GR.; W. E. T.; G. K. H.)

**STUKELEY, WILLIAM** (1687–1765), English antiquary and physician, born at Holbeach, Lincolnshire, on Nov. 7, 1687, is remembered especially for his studies of such archaeological sites as the great stone circles of Avebury and Stonehenge (q.v.). His surveys of these monuments in the 1720s are still of considerable interest, and he made extensive antiquarian travels recorded in his *Itinerarium curiosum* (1724). His accounts of Stonehenge and Avebury were published in 1740 and 1743 respectively, by which time Stukeley had developed extravagant theories relating the Druids to such stone circles. These views were widely and enthusiastically accepted in the late 18th century (see DRUIDISM). He died in London on March 3, 1765.

See S. Piggott, *William Stukeley* (1950). (S. Pr.)

**STUMPF, CARL** (1848–1936), German philosopher and theoretical psychologist known principally for his work on the psychology of music, was born in Wiesentheid, Bavaria, April 21, 1848. A precocious child and a musical prodigy, he received his education at home, in the gymnasia of neighbouring towns, at Würzburg with Franz Brentano, and at Göttingen with Hermann Lotze, from whom he received his Ph.D. in 1868. After two years of further study with Brentano at Würzburg he habilitated as a dozent at Göttingen in 1870. In the spring of 1873 he published his first book, *Über den psychologischen Ursprung der Raumvorstellung* ("The Psychological Origin of Space Perception"), which won him the chair at Würzburg that autumn. During the next two decades, Stumpf changed his affiliation many times, moving to Prague (1879), Halle (1884), Munich (1889), and finally to Berlin (1894), where he held the chair in philosophy and the directorship of the laboratory until he retired in 1921. Stumpf was joint president of the International Congress of Psychology in Munich (1896); founded the *Beiträge zur Akustik und Musikwissenschaft* ("Contributions to Acoustics and Musicology," 1898); established the *Phonographische Archiv* of primitive music (1900); and served as rector of the university (1907–08). He died at Berlin on Dec. 25, 1936.

Stumpf's chief books are *Tonpsychologie*, 2 vol. (1883-90); *Über Leib und Seele* ("Body and Soul," 1897); *Philosophische Reden und Vorträge* ("Philosophic Speeches and Lectures," 1910); *Die Anfänge der Musik* ("The Origins of Music," 1911); and *Die Sprachlaute* ("The Sounds of Speech," 1926).

See H. S. Langfeld in the *Amer. J. Psychol.*, 49:316-320 (1937).

(K. M. D.)

**STUMPF, JOHANNES** (1500-1578?), Swiss chronicler and theologian and one of the most important personalities of the Swiss Reformation. He was born in Bruchsal, Ger., on April 23, 1500, and in 1521 entered the order of the Knights of St. John in Freiburg im Breisgau, a year later being appointed prior at Bubikon, Zürich. He there declared himself for the Reformation and, as the friend of Zwingli, worked faithfully for the Reformers until his retirement in 1562. He died in Zürich between Martinmas (Nov. 11) 1577 and Martinmas 1578.

Stumpf's enduring fame rests upon his *Gemeiner loblicher Eydgnoschaft Stetten, Landen und Völkern chronikwirdiger Thaaten beschreibung* (1547-48), probably the most famous of Swiss chronicles. It remained a standard work until the 18th century. Like his many other books, it is marked by its combination of objectivity with intensity of participation.

See Stumpf's *Schweizer- und Reformationschronik*, ed. by E. Gagliardi, H. Müller, and F. Büsser, 2 vol. (1953-55) and his *Beschreibung des Abendmahlsstreites zwischen Zwingli und Luther*, ed. by F. Büsser (1959).

(F. B.)

**STUPA**, Buddhist religious building, also called a tope or dagoba, consisting of a solid mass of masonry, built above a receptacle containing a sacred relic. Although the origin of the stupa was probably the more primitive tumulus, or mound of earth over a grave, its development in historic times was toward greater and greater height and richness of treatment. Outside Tibet and China, a profile generally conical and of great height was developed, as in the famous gilded example in the centre of the Shwe Dagon, in Rangoon. The Tibetan form, developed to a great degree of beauty and richness in China, has a bulbous silhouette, wider near the top than at the bottom. The most famous of the Indian stupas is the largest of a group at Sanchi, which is generally attributed to the time of Asoka (3rd century B.C.). In the stupa proper is surrounded by a circular walk, around which is a richly decorated stone fence, pierced by four richly sculptured gateways, the whole designed in forms manifestly reminiscent of wooden construction.

See also **TEMPLE ARCHITECTURE**; **INDIAN ARCHITECTURE**; and references under "Stupa" in the Index.

**STURDZA**, a great Rumanian boyar family that is recorded from the 15th century, when it owned land at Valea Berheciului in Moldavia. Several of its members were prominent at the court of the Moldavian princes in the 16th-17th centuries. In the 19th century it reached the zenith of its importance.

IOAN SANDU STURDZA was prince of Moldavia from 1822 to 1828, the first to hold that rank after the fall of the Phanariot regime. He supported the liberalism of the petty boyars, and his draft of a constitution was the first in Moldavian history, but in 1828 he was deposed by the Russians.

MIHAI, or MICHAEL, STURDZA (1795-1884) was prince of Moldavia from 1834 to 1849. He founded the high school at Iași known as the Academia Mihăileană, emancipated the gypsies from serfdom (1844), and forcefully suppressed the popular insurrection of 1848. His son GRIGORE (1821-1901) served with the Turkish Army in the Crimean War under the name and title of Muhlîs Pasha and was a candidate for the princely throne of Moldavia in 1859.

ALEXANDRU STURDZA (1791-1854), a cousin of Prince Michael, was a diplomat in the Russian service. A champion of the Orthodox Eastern Church against Roman Catholicism, he wrote numerous philosophical works in Rumanian, many of which were translated into other languages. His sister ROXANDA (1786-1844), who as Countess Edling exercised some influence at the court of the Russian emperor Alexander I, wrote verse in French. Another writer was ALEXANDRU A. STURDZA (1867-1917), author of works in French on Rumanian historical subjects.

DIMITRIE ALEXANDRU STURDZA (1833-1914), statesman and four times prime minister of Rumania, was born at Miciăușeni, near Iași, on March 10, 1833. After studies in Germany, he became secretary to the Moldavian *divan ad hoc* of 1857 and then secretary to the commission of 1858 (see **RUMANIA: History**), which prepared the de facto unification of Moldavia and Walachia under Alexandru Ion Cuza (*q.v.*). He later opposed the agrarian reform sponsored by Cuza, whose abdication he helped to bring about. He then favoured the accession of Prince Charles of Hohenzollern-Sigmaringen to the Rumanian throne (see **CAROL I**). In the cabinets of Ion Ghica and Ion C. Brătianu, he was successively minister of public works, of finance, of education, and of foreign affairs. Chairman of the Liberal Party from 1892, he was prime minister in 1895-96, 1897-99, 1901-04, and 1907-09; he severely suppressed the peasant rising of 1907. He also published works on Rumanian foreign policy and on numismatics, and some major collections of historical documents; and from 1909 he was secretary-general of the Rumanian Academy. He died in Bucharest in October 1914.

**STURE**, the name of several Swedish noble families, only distantly related, to which belonged three regents of Sweden in the late Middle Ages, who to some extent epitomized national resistance to rule by Danish kings: the regents Sten Sture the Elder, Svante (Nilsson) Sture, and Sten Sture the Younger.

STEN STURE THE ELDER (c. 1440-1503) was appointed regent on the death (1470) of King Charles VIII and established himself in office by defeating the Danish king Christian I at Brunkeberg outside Stockholm (1471). Sten Sture gradually increased his power by ruthlessly playing off various factions in the *riksråd* (council) and nobility against each other. By the mid-1490s he had a firm grip on central and local administration, and had at his disposal the strongest castles in the country. He had deprived the *riksråd* of the possibility of independent intervention in governmental affairs. Then, because of the untenable external political situation—war on two fronts with Denmark and Russia—he was forced in 1497 to yield to the Danish king John (Hans). In 1501, through an uprising, he again became regent until his death in 1503. His administrative and military changes are regarded as the basis on which the Swedish monarchy achieved stability in the 16th century.

SVANTE (NILSSON) STURE (c. 1460-1512), succeeding as regent in 1503, tried to continue his predecessor's politics but lacked his fixity of purpose and energy. He mastered neither internal nor foreign affairs and was forced to make repeated concessions to the *riksråd*. The latter appeared to be gaining the upper hand when Svante Sture died suddenly in 1512.

STEN (SVANTESSON) STURE THE YOUNGER (c. 1492-1520) secured the regency for himself despite the opposition of the *riksråd*. He proved to be a master at neutralizing his political opponents by means of sudden coups, unscrupulous propaganda, and systematic persecution. He quickly restored the regency's former authority, then forced the *riksråd* into complete submission and subordinated the church to the state. Against Denmark he conducted a policy of procrastination which gave the country much-needed peace. When the war again broke out he warded off two Danish attacks, but in the third (1520) he himself was wounded and died.

(G. T. WE.)

**STURGE, JOSEPH** (1793-1859), English philanthropist and political reformer, who was a leading member of the antislavery movement, was born at Elberton, Gloucester, on Aug. 2, 1793, the son of a farmer. After abandoning farming for corn dealing in 1814, he settled in Bewdley, Worcestershire. He came from a Quaker family and founded a branch of the Peace Society in Worcester in 1818 and organized the local antislavery movement. He moved to Birmingham in 1822 and became secretary of the Birmingham branch of the Anti-Slavery Society in 1826, but he soon went beyond Quaker politics and joined the Birmingham Political Union, founded by Thomas Attwood in 1829. His business interests prospered, but he retained his zeal for the antislavery movement even after the act of 1833 which abolished slavery in the British colonies. He toured the West Indies in 1836-37, collecting evidence of continued ill-treatment of Negroes, and in 1839 he was

one of the founders of the new British and Foreign Anti-Slavery Society, designed to press for the abolition of slavery throughout the world.

From the antislavery movement he turned to the domestic battles for repeal of the corn laws and extension of the suffrage, and brought both causes together in the National Complete Suffrage Union, which he founded in 1842. He was unable, however, to unite repealers and Chartists in one common agitation, and the union failed in 1844 amid recriminations on both sides. Sturge failed to win a seat in Parliament but continued to support the causes in which he believed. He was an assiduous attendee, for example, of world peace conferences, and in January 1854, on the eve of the Crimean War, he went as a Quaker emissary to Russia to plead with Nicholas I. In May 1858 he became president of the Peace Society. He died at Edgbaston, Birmingham, on May 14, 1859. (A. Brl.)

**STURGEON**, a sharklike bony fish of the family Acipenseridae, of ancient lineage. The more than 20 species are found only in the Northern Hemisphere. Several of them provide caviar (from eggs) and isinglass (from the swim bladders). Most sturgeons pass a great part of the year in the sea, but periodically ascend large rivers, some in spring to deposit their spawn, others later in the season; a few are confined to fresh water.

Sturgeons are identified by bony plates covering the head and by five rows of bony shields along the body, one along the back, one on each side above the pectoral fin, and one on each side near the belly. The tail fin is unequal, the upper lobe being longer than the lower. The toothless mouth, on the underside of the snout, is preceded by four fleshy feelers. The lips are protractile and have taste buds surrounding them. The form of the snout becomes more blunt and abbreviated with age.

Sturgeons are ground feeders that spend much time in foraging, dragging their tactile barbels over the bottom in search of food. They are found in the greatest abundance in the rivers of southern Russia during the two weeks of the upstream migration and in the freshwaters of North America. Early in summer the fish migrate into the rivers or toward the shores of freshwater lakes in large shoals for breeding purposes. The ova are small and numerous. The growth of the young is rapid. After the sturgeon attains maturity, growth continues for several years, but slowly. Some attain great age: observations made in Russia indicate that the hause or beluga (*Huso huso*) may attain an age of between 200 and 300 years. Sturgeons ranging from 8 to 11 ft. (2 to 3 m.) in length are by no means scarce, and some species grow to a much larger size.

The common sturgeon (*Acipenser sturio*) occurs from Scandinavia to the Mediterranean. A very closely related form, considered by some authorities to be of the same species, occurs along the east coast of North America from the St. Lawrence River to the Gulf of Mexico. Females, which are larger than the males, reach a length of at least 12 ft. (4 m.); and specimens of 18 ft. (5.5 m.) have been reported. They feed on bottom-living invertebrates and fishes. They spawn in late spring and early summer.

*A. guldenstadtii* is one of the most valuable species of the rivers of the Soviet Union, extending from Russia eastward as far as Lake Baikal. It attains the same size as the common sturgeon and abounds particularly in the rivers of the Black and Caspian seas. A smaller species, the sterlet (*A. ruthenus*), inhabits the Black and Caspian seas.

*A. stellatus* occurs in abundance in the rivers of the Black Sea and of the Sea of Azov and the Caspian Sea. It has a long and pointed snout like the sterlet. Its flesh is highly esteemed and its caviar and isinglass bring the highest price.

The lake sturgeon of North America (*A. fulvescens*) occurs in the Mississippi Valley, the Great Lakes, and northward into Canada. A few thousand pounds a year are caught commercially. The white, Oregon or Sacramento, sturgeon (*A. transmontanus*) occurs on the Pacific coast of North America from Monterey to Alaska. It is identified by bony plates between the ventral fins and by small anal fins in two rows of 4 to 8. It is one of the three largest species, growing to nearly 2,000 lb., according to old accounts. Almost half a million pounds are caught annually.

The beluga is another of the large species, reaching a length of 24 ft. (more than 7 m.) and a weight of 3,000 lb. It inhabits the Caspian and Black seas, and the Sea of Azov. Its flesh, caviar, and air bladder are of less value than those of the smaller kinds.

The family Acipenseridae includes one other genus, *Scaphirhynchus*, the shovelhead or shovelnose sturgeon, distinguished by the long, broad, flat snout and the union of the longitudinal rows of scales posteriorly. All the species are confined to freshwater. One of them is common in the Mississippi and other rivers of North America; the other three occur in the larger rivers of eastern Asia.

The flesh of sturgeon is sold fresh, pickled, or smoked. Caviar consists of the eggs, which have been separated from the surrounding tissue of the roe, sometimes washed in white wine or vinegar, and pickled with salt. The largest production of sturgeon caviar is in the U.S.S.R. The inner membrane of the swim bladders, which is removed by a process of washing and air drying, is used in the preparation of isinglass, which is a very pure form of gelatin used for a variety of industrial purposes, e.g., in clarification of wine and beer, for making jellies, and for special cements. (L. A. Wb.)

**STURGEON BAY**, the seat of Door County, in northeastern Wisconsin, U.S., 145 mi. (233 km.) N of Milwaukee, is a lake port. The city is on an inlet of the same name on the western or Green Bay side of the Door Peninsula in Lake Michigan. The federal government maintains a ship canal constructed across the peninsula in 1878. Activities of earlier days were sawmilling, which began in the 1850s, and the quarrying of limestone. The city derives income from the processing of red cherries, for which the surrounding region is famous; from manufacture of shoes and leatherwork; and from shipbuilding and the handling of water freight. The scenic beauty of the area makes the city the headquarters of an important tourist trade. It has one of the largest yacht storage facilities on the Great Lakes. For comparative population figures see table in WISCONSIN: Population.

(W. F. Ry.)  
**STURGIS, RUSSELL** (1836–1909), U.S. architect and author of a number of books on art, was a perceptive critic of the architecture of his time, being, for example, one of the first writers on architecture to appreciate the work of Frank Lloyd Wright. Sturgis was born in Baltimore County, Md., on Oct. 16, 1836. He graduated from the Free Academy in New York (now the City College of New York) in 1856, studied architecture under Leopold Eidlitz and then for two years in Munich, returning to the United States in 1862. He designed the Yale University Chapel and the Farnham and Durfee dormitories at Yale, the Flower Hospital, New York, the Farmers' and Mechanics' Bank, Albany, N.Y., and many other buildings. He edited *A Dictionary of Architecture and Building*, 3 vol. (1901–02) and the English version of Wilhelm Lübke's *Outlines of the History of Art*, 2 vol. (1904), and wrote *European Architecture* (1896), *How to Judge Architecture* (1903), *The Appreciation of Sculpture* (1904), *The Appreciation of Pictures* (1905), *A Study of the Artist's Way of Working in the Various Handicrafts and Arts of Design*, 2 vol. (1905), and an unfinished *History of Architecture* (1906 et seq.). He died in New York City on Feb. 11, 1909.

**STURM, (JACQUES) CHARLES FRANÇOIS** (1803–1855), Swiss mathematician of Alsatian parentage, who was the originator of the Sturm theorem of equations, was born at Geneva on Sept. 29, 1803, and entered the university there in 1818. The death of his father meant that while there he had to support his family by private coaching. He visited Paris in 1823, as tutor to the de Broglie family, through whom he met many of the leading French men of science. He finally settled there in 1825. With Colladon, in 1826, he made the first accurate determination of the velocity of sound in water, and a year later wrote a prize essay on compressible fluids. The theorem which bears his name, regarding the number of real roots of a numerical equation included between given limits, was discovered in 1829 (see EQUATIONS: THEORY OF). His work on what is now called the Sturm-Liouville theory of differential equations of the second order was published in 1834 and won for him the Grand Prix des Sciences Mathématiques (see also LIOUVILLE, JOSEPH). He was elected to the

Académie des Sciences in 1836, and was appointed to the staff of the École Polytechnique in 1838. Finally he succeeded Siméon Denis Poisson in the chair of mechanics in the Faculté des Sciences in Paris in 1840. He died in Paris, on Dec. 18, 1855. His *Cours d'analyse de l'école polytechnique* (1857–63) and *Cours de mécanique de l'école polytechnique* (1861) were published posthumously. Although primarily an analyst, Sturm made significant contributions to projective geometry and to the differential geometry of curves and surfaces. (G. A. B.)

**STURSA, JAN** (1880–1925), one of the leaders of the modern school of Czech sculpture, was born at Nové Město in Moravia on May 15, 1880. In 1899 he entered the Academy of Fine Arts at Prague as a pupil of the influential teacher J. V. Myslbek. His early works manifest the character of the symbolic literature of the period, and reflect also the plastic qualities of Rodin's sculpture. His individuality began to proclaim itself in such lyric works as "Puberty" (1905), "The Melancholy Girl" (1906), and "Primavera" (1907). A journey to Italy in 1907 was the opening of a new epoch in his development. "Eve" (1908, State gallery, Munich), "Hetaïra" (1909), and the later "Gift of Heaven and Earth" demonstrate his sensitivity to feminine beauty as well as, stylistically, a tendency toward simplification of sculptural form and increasing expressive strength. Occasional excursions into extremes of sensuality, as in his monumental representation of the dancer "Sulamith Rahu" (1911, Venice), were not sustained. His decorative commissions, notably the groups for the pylons of the Hlavka bridge at Prague, are marked by intricate compositional massing restrained by strong, almost geometric, tensions. Stursa's war experiences gave to his mature style a tragic and more profound character, as in "Wounded Man" (1916), expressed in bold and vigorous sculptural terms. In 1916 he became professor in the Academy of Fine Arts at Prague, and in 1923–24 its director. He produced a number of portrait busts, the most noteworthy being "President Masaryk." Stursa died in Prague on May 2, 1925.

See A. Matějček and Z. Wirth, *Modern and Contemporary Czech Art* (1924). (N. L. R.)

**STURZO, LUIGI** (1871–1959), Italian priest and political organizer, promoter of the Christian Democratic movement in Italy, was born at Caltagirone, Sic., on Nov. 26, 1871. He studied at the Gregorian University, Rome, and became professor of philosophy and sociology in his native town. On the outbreak of World War I he went to Rome as secretary of Azione Cattolica (Catholic Action). In 1919 he founded the Partito Popolare and became its first political secretary. Sturzo and his party took their stand on papal encyclicals concerning the social order and advocated reforms of a radical nature, especially in agriculture.

At the elections of November 1919 the newly founded Partito Popolare secured 101 seats and became a dominant force in politics, if not with the Giolitti Cabinet certainly during the subsequent Bonomi Cabinet. After the Fascist "march on Rome" several Popolari entered the first Mussolini Cabinet, but soon the party joined the opposition. In 1923, however, the Vatican, subjected to pressure from Mussolini, withdrew its support from Sturzo in an attempt to reach some understanding with the Fascists. Sturzo's party had by now much shrunk as an outcome of Fascist electoral methods. He resigned the leadership in 1923 and left Italy in October 1924. Sturzo spent his 20 years of exile first in London and after the outbreak of World War II in the U.S. His party in Italy was driven underground, but after the overthrow of Fascism many of his ideas reemerged in the Christian Democratic Party, headed by Alcide de Gasperi and other followers of Sturzo, who revered him as the father of their ideas. He returned to Italy after the war and was made a senator for life in 1952. He died in Rome on Aug. 8, 1959. His books include *Italy and Fascism* (1927), *Church and State* (1939), *Italy and the Coming World* (1945), and other works not translated into English. (B. WL.)

**STUTTERING:** see SPEECH DISORDERS.

**STUTTGART**, the capital of the *Land* (state) of Baden-Württemberg, Federal Republic of Germany, lies on both banks of the Neckar, a tributary of the Rhine, approximately 120 mi. (190 km.) N.W. of Munich and 70 mi. (110 km.) E.N.E. of Stras-

bourg in France. Stuttgart lies in the midst of woods, orchards and vineyards, but it is also an important industrial town and notable for its modern architecture. Some of the earliest work on the invention of the motorcar was done in Stuttgart and the oldest motorcar factory in the world is there. Pop. (1961) 637,539.

In the centre of the town is the Schillerplatz with a statue of Schiller by B. Thorwaldsen (1839), the old castle which dates from the 13th century (completed 1553–78) and now houses the state museum with its collection of prehistoric and historic objects, and the Stiftskirche (collegiate church), a 12th-century Romanesque basilica completed in the late Gothic style (1436–95). Immediately to the northeast is the Schlossplatz with its Jubilee column (1841–46), one of the most beautiful squares in Germany. In it is the new palace (1746–1807), built on a typical 18th-century plan; it was burned in 1944 and under reconstruction in the 1950s. Farther to the northeast are the Theater-Anlagen, with rose and other gardens, and the opera house of the Württemberg State opera along its eastern side. These gardens are continued northeast by the Schlossgarten Anlagen, with the main railway station on its west, to the Neckar, which there takes a right-angle turn to the northeast. On its left bank are the Wilhelma botanical and zoological gardens and the Rosenstein palace (1825–29), now the natural history museum. To the north and over the river is Bad-Cannstatt which, with Stuttgart-Berg on the other bank, has many mineral springs; the number of baths and swimming pools, mineral and otherwise, is a notable feature of the town. The city church in Bad-Cannstatt was built in 1471–1506. Along the east bank of the river lies the Cannstatter Wasen, a large sports ground with a sports stadium holding 100,000 spectators; every autumn the big Cannstatter folk festival is held there. The rococo Solitude palace (1763–67) stands in the wooded hills to the west of the town; Hohenheim palace (1768–85), housing the college of agriculture, is to the south. In the north of the city is the Höhenpark Killesberg, a large park with exhibition halls, an observation tower, chair lift and miniature railway, and adjoining it to the southeast is the Weissenhof estate, built in 1927 by 16 German and other architects. Other modern buildings include the town hall (1954–56) in the market place, south of the Schillerplatz; the television tower (1955), to the south, which is 633 ft. high with an observation platform and restaurant; the Stuttgarter Liederhalle (concert and congress hall) built in 1954–56. Not far from the market place is the late Gothic St. Leonard's church (1463–74), of special interest as being of the hall type with nave and aisles of the same height.

Stuttgart has a technical college and institutions for agriculture, music, art and architecture. The Staatsgalerie, in Neckarstrasse, has German paintings up to the 20th century and 15th- to 17th-century Dutch and Italian pictures. The Württemberg Land library in the Urbanstrasse contains the second largest collection of Bibles in the world. One of the most interesting of the museums is the Daimler-Benz automobile museum in Untertürkheim on the east bank of the Neckar. Gottlieb Daimler's tomb is in the Uff cemetery in Bad-Cannstatt and a memorial to him stands in the park there.

Stuttgart is an important transport junction at the centre of railway connections stretching all over Europe. It lies on two *Autobahnen* (Frankfurt-Munich-Salzburg and Stuttgart-Heilbronn) and has an airport 8 mi. from the city. The port, which is at the end of the Neckar, was opened in 1958 and will take shipping up to 1,200 tons. The city is the largest industrial centre in southwest Germany. Electrical engineering is of primary importance, followed by vehicle and machine construction. Textiles, clothing, precision tools, foodstuffs, luxury wooden and leather goods, shoes, musical instruments, chemicals and paper are manufactured. There are also large breweries. Stuttgart has a special reputation as a book centre, with numerous printing works and more than 200 publishing houses.

Settlements existed in the area of what is today Bad-Cannstatt in prehistoric times, and the Romans established a fort there. Stuttgart itself developed from a *Stuotgarten*, a *Gestüt* or stud farm, which was set up in about 950. It developed into a town

about 1254 under Count Ulrich "the Founder." In 1495 it became the capital of the new dukedom of Württemberg, which in 1806 became a kingdom. With the industrial revolution, the court and administrative town quickly expanded, its population rising from 48,000 in 1850 to 177,000 in 1900 and 460,000 in 1939. (U. S.)

**STUYVESANT, PETER** (1610–1672), Dutch colonial governor who tried to resist the English seizure of New York, was born in Scherpenzeel, Friesland, son of a Calvinist minister. He began his career in the Dutch West India Company about 1632, and in 1643 became director in the company's colonies of Curacao, Aruba, and Bonaire. While he was unsuccessfully attacking the Portuguese island of Saint Martin, his right leg was severely injured and had to be amputated. Thereafter he wore a wooden leg. In 1645 he was selected by the company to supersede Willem Kieft as director general of all Dutch possessions in North America and the Caribbean. He arrived in New Amsterdam (later New York City) in 1647 and energetically set about renovating the government of the colony of New Netherland and the fortunes of the nearly bankrupt company.

Almost immediately began his lasting conflict with the burghers, who were alienated by his violent and despotic methods and his devotion to the interests of the company. In response to the demands for self-government he and the council in 1647 appointed an advisory board of nine, and in 1653 there was established the first municipal government for the city of New Amsterdam, modeled after that of the cities of Holland. These concessions, however, proved hollow, for Stuyvesant never ceased to dominate the government. He also aroused opposition because of his efforts to improve the system of defense and to prevent the sale of liquor and firearms to the Indians, and because of his persecutions of Lutherans and Quakers, to which the company finally put an end. In 1650 he sacrificed a large amount of territory in a settlement of the boundary between New Netherland and Connecticut. He succeeded, however, in dislodging the Swedes from their settlement in Dutch territory on the Delaware and in establishing peace with the Indians. In August 1664 the British, led by Col. Richard Nicolls with four ships and about 300 or 400 men, seized New Netherland, which Charles II of England had granted his brother, the duke of York. Stuyvesant was forced to surrender when the burghers refused to aid him. The West India Company made him the scapegoat for what actually were defects in company policies. He spent the remainder of his life on his New York farm, "the Bouwerie," from which New York City's "Bowery" takes its name. He died in February 1672 and was buried in a chapel on the site of which in 1799 was erected St. Mark's Church.

See Henry H. Kessler and Eugene Rachlis, *Peter Stuyvesant and His New York* (1959). (E. S. Bv.)

**STYLE, LITERARY**, involves the selection and organization of the features of language for expressive effects, and includes all uses of sound patterns, words, figures of speech, images, and syntactic forms. In an absolute sense, the word "style" (Lat. *stilus*, "writing-rod") means a good or distinguished manner with language, as in: "Proust has style," or "Theodore Dreiser lacks style." Prose style only is treated here (see also POETRY; POETIC IMAGERY; PROSE; RHETORIC; ORATORY; FIGURES OF SPEECH; LANGUAGE: *The Structure of Language*).

**Views on Style.**—Aristotle, Cicero, and Quintilian treated style as the proper adornment of thought. In this view, which prevailed throughout the Renaissance period, devices of style can be catalogued. The essayist or orator is expected to frame his

ideas with the help of model sentences and prescribed kinds of "figures" suitable to his mode of discourse.

Jonathan Swift's dictum on style, "Proper Words in Proper Places" (in *A Letter to a Young Gentleman, Lately Enter'd into Holy Orders*, 1721), stands midway between the idea of style as something properly added to thoughts, and the 20th-century ideas that derive from Charles Bally (1865–1947), the Swiss philologist. According to followers of Bally, style in language arises from the possibility of choice among alternative forms of expression, as for example, between "children," "kids," "younsters," and "youths," each of which has a different evocative value. Any expression may give rise to a variety of effects, and the effect will be more forceful as the expression deviates from normal usage. Thus style depends on choice, evocation, polyvalency, and deviation in language. This theory emphasizes the relation between style and linguistics.

Style is also seen as a mark of character. Buffon's famous epigram, "*Le style est l'homme même*" ("Style is the man himself") in his *Discours sur le style* (1753), and Schopenhauer's definition of style as "the physiognomy of the mind" suggest that, no matter how calculatingly choices may be made, a writer's style will bear the mark of his personality. Style is "the mental picture of the man who writes," to quote Edmund Gosse's article "Style" for the 11th edition of *Encyclopædia Britannica* (1911). This view would account for the underlying consistency of individual styles. An experienced writer is able to rely on the power of his habitual choices of sounds, words, and syntactic patterns to convey his personality or fundamental outlook. Some effects of the possible choices are illustrated below.

**Syntax.**—Different expressive effects arise from every kind of phrase, clause, and sentence; from coordination and subordination, parallelism, word order, grammar, and other sentence features.

**Loose and Periodic Sentences.**—The distinction between the loose sentence (in which the main clause is completed early and other main clauses or subordinate ones follow) and the periodic (in which the main clause is not completed until the end) is central to style. Tacitus used the loose structure, with curt main clauses, for swift movement and smart concision: "*Quattuor principes ferro interempti: trina bella civilia, plura externa ac plerumque permixta: prosperae in Oriente, adversae in Occidente res: tumultum Illyricum, Galliae nutantes, perdomita Britannia et statim omissa*" ("Four emperors perished by the sword; there were three civil wars; there were more with foreign enemies; there were often wars that had both characters at once. There was success in the East, and disaster in the West. There were disturbances in Illyricum; Gaul wavered in its allegiance; Britain was thoroughly subdued and immediately abandoned"; *Historiae*, I, ii, c. A.D. 110). Sir Thomas Malory demonstrates the ease and flow of loose structure; Rabelais shows how flexible and informal it can be. Periodic structure is more apt to increase tension, heighten detail, and command attention, since the meaning is held in suspense. Cicero used a lengthy periodic structure to great emotional effect in the "grand style" (*genus grande*) of his oratory; Macaulay used a short variety, with dramatic twists in meaning, for surprise, as in "To this step, taken in the mere wantonness of tyranny, and in criminal ignorance or more criminal contempt of public feeling, our country owes her freedom" (*History of England*, 1848).

**Parallelism.**—Parallelism can be a means of ordering, emphasizing, or pointing out relations in the sentence; to some degree it is a feature of all good prose. In John Lyly's *Euphues* (1578) transverse alliteration is used to draw attention to parallel structure, as in "Ah my Philautus, if the wasting of our money might not dehort us, yet the wounding of our minds should deter us." Such emphasis can cloy; but parallelism lends wit and authority to the antithetic aphorism, as in La Rochefoucauld's "*Nous aimons toujours ceux qui nous admirent, et nous n'aimons pas toujours ceux que nous admirons*" ("We always love those who admire us, but we do not always love those whom we admire"; *Maximes*, 1665). John Henry Newman, in his *Apologia pro vita sua* (1864), used chiasmic or inverted parallel structure for strong emphasis: "I have changed in many things: in this I have not."

1660–70

**Word Order.**—Expressive effects of word order are most forceful when words are in prominent positions (e.g., at the end of the sentence) or out of their usual order. In Thomas Love Peacock's sentence "King Gwythno had feasted joyously, and had sung his new ode to a chosen party of his admiring subjects, amidst their, of course, enthusiastic applause" (*The Misfortunes of Elphin*, 1829), humour results from the placing of the "of course" in a logical, rather than a conventional, position. Flaubert's word order can mirror psychological processes, as in "*Au milieu de cette ombre, par endroits, brillaient des blancheurs de baïonnettes*" (*L'Éducation sentimentale*, 1869). Here the order of the words follows the order of impressions as they occur to the onlooker: "ombre" (darkness), "endroits" (parts), "brillaient" (shone), "blancheurs" (whiteness), and "baïonnettes" (bayonets).

**Grammar.**—Different grammatical forms give rise to different expressive effects. In "Bill kissed Sally" and in "Sally was kissed by Bill" the same event is described; but the passive form focuses attention on Sally (and what happened to her) and the active on Bill (and what he did). In dialogue, and in psychological realism, grammatical conventions are sometimes violated for effect. For example, Dickens put into the mouth of his quick-witted scalawag, Mr. Alfred Jingle, such staccato asyntactical speeches as "Epic poem,—ten thousand lines—revolution of July—composed it on the spot—Mars by day, Apollo by night,—bang the field-piece, twang the lyre" (*The Pickwick Papers*, 1836–37). In such sentences as "Invent a story for some proverb which?" James Joyce depicted half-thoughts running through Mr. Bloom's mind in *Ulysses* (1922).

**Other Sentence Features.**—Complication in structure, sentence length, punctuation, and various typographical devices can all be expressive. Thomas Carlyle used heavy punctuation, italics, and many capitals in involuted sentences to underline his role as an original prophet, as in "All Anarchy, all Evil, Injustice, is, by the nature of it, *dragon's-teeth*; suicidal, and cannot endure" (*The French Revolution*, 1837).

**Words.**—**Word-forms.**—Although word-formation normally allows little scope for expressive choice, since most word-forms are fixed, some styles make effective use of it. Lewis Carroll's portmanteau word "chortle" ("chuckle" + "snort") is a device of comic wit; Gerard Manley Hopkins' "inscape" ("inside" + "landscape") expresses a new vision of reality. James Joyce, in *Ulysses*, freely compounded words (e.g., "softcreekfooted," "husbandwords," and "the swiftseen") for various rhythmic and emphatic effects. In *Finnegans Wake* (1939) he developed a system of "polyphonic" terms to delineate the subconscious mind, where meanings (often comically) merge and overlap: e.g., "funnominal," "jinglish janglage," and "tellibly divilcult." Dickens, with such forms as "buzzums," "creetur," "umble," and "excuge," vigorously characterized the speakers in his novels; and misspellings, in fictional epistles and dialogue, for example, can be very expressive.

**Word-meanings.**—The widest scope for style is offered at the level of word-meanings. Phrases such as "the little house," "the diminutive house," and "the petite house" have overlapping or synonymous meanings, but "little" may suggest endearment as well as size; "diminutive," good construction; and "petite," prettiness. Synonymy enables the writer to choose the word that has the evocative value he wants. Samuel Johnson habitually used general, abstract, and nonemotive words: "This quality of looking forward into futurity seems the unavoidable condition of a being, whose motions are gradual, and whose life is progressive" (*The Rambler*, no. 2, 1750). Many English essayists have preferred particular, concrete, and emotive words; but great thoughts, Johnson claimed, "are always general." Evocative values are attached also to slang, technical, dialect, colloquial, formal literary, and standard contemporary words, as well as to archaisms and foreign expressions. George Meredith used the archaic "damsel" to suggest the immaturity of a heroine; Ronald Firbank, in "Mrs. Henedge lived in a small house with killing stairs just off Chesham Place" (*Vainglory*, 1915), characterized Mrs. Henedge with a colloquially used "killing," in stark and witty contrast to the standard words around it. Only a mention can be made here of im-

agery and ambiguity as rich sources of possibility in word style. In general, the gap between the image and the object is smaller in prose than in poetry; farfetched images are a mark of preciosity or inflated style (see also EUPHUISM).

**Sounds.**—**Rhythms.**—Aristotle maintained that while prose should not lack rhythm it should avoid metre; and metrical prose often has achieved only that "flatness" and "disenchantment" that R. L. Stevenson complained of. Lyly used the classical schemes of isocolon (like-length in phrases or clauses) and parison (like-length + like-form) to give close rhythmic order to prose, as in "I will to Athens there to toss my books, no more in Naples to live with fair looks" (*Euphues*), where rhyme is another device of order; and Dickens used isocolon for emphasis, as in "So I called myself Pip, and came to be called Pip" (*Great Expectations*, 1860).

Thomas Mann imitated the musical "leitmotiv" of Wagner by assigning special rhythms (and words) to recurrent characters and symbols, as in "*Die blonde Inge, Ingeborg Holm*," "*Inge Holm, die lustige Inge*," and "*Ingeborg, die blonde Inge*" (*Tonio Kröger*, 1903). In general, except in prophetic writing (e.g., Nietzsche, and parts of the Bible) and oratory (e.g., Cicero, and Winston Churchill), good prose avoids insistent or obvious rhythms.

**Phonemic Pattern.**—The expressive effect of any phrase, clause, or sentence is partly determined by the pattern of its speech-sounds or phonemes. Alliteration lends dignity and force to the 14th-century devotional prose of Richard Rolle of Hampole, as in "It wanes in to wretchednes, be welth of his worlde." Later writers have also used alliteration to point out and underline relations in meaning, as in Jane Austen's simple "She watched him well" (*Emma*, 1815). Unobtrusive sound repetition is vital to euphony as well as to clarity. In Emily Brontë's sentence "She rang the bell till it broke with a twang; I entered leisurely" (*Wuthering Heights*, 1847), contrasting sounds fit contrasting actions, and euphony—in its fullest sense of "pleasing sound"—is perfectly achieved.

**STYLITE**, Christian ascetic who lived standing on top of a column (Greek *stylos*). The first to do this was the 5th-century St. Simeon Stylites (q.v.) in Syria, and the best-known among his imitators are his Syrian disciple St. Daniel (409–493) in Constantinople, St. Simeon Stylites the Younger (517–592) on Mt. Admirable near Antioch, St. Alypius the Paphlagonian (7th century), St. Luke (879–979) at Chalcedon, and St. Lazarus (968–1054) on Mt. Galesion near Ephesus. Apart from these saints, of whom Greek lives exist, various other Stylites, named and unnamed, appear in ecclesiastical sources, living in Greece and the Middle East. John Moschus (d. 619) in his *Pratum spirituale* mentions several, including Monophysites, and references to women Stylites have been found. But the practice never spread to the West, where only an abortive attempt is recorded: St. Gregory of Tours in his *Historia Francorum* describes meeting St. Wulfiaicus, then a deacon at Yvoi (near Carignan, Ardennes), who had tried living on a column but was soon forbidden by the bishops to pursue this extreme form of asceticism. The Stylite was permanently exposed to the elements, though he might have a little roof above his head, stood night and day in his restricted area, usually railed round, and was dependent for his scanty sustenance on what his disciples

brought him by ladder. He spent most of his time in prayer but also did pastoral work among those who gathered around his column.

See H. Delehay, *Les Saints stylites* (1923); Eng. trans. of life of St. Daniel in E. Dawes and N. H. Baynes, *Three Byzantine Saints* (1948).

**STYLOLITE.** A common feature in limestone, marbles, and similar rock is a series of relatively small, alternating, interlocked, toothlike columns of stone called stylolites. The term is taken from the Greek *stylos* meaning "pillar" or "column." The individual columns never appear singly but occur as a succession of interpenetrations which in cross section make a zigzag suture across the face of the stone. There has been much controversy over their origin since they were first described in 1751. However, geologists generally submit to the preponderance of field evidence supporting the theory of secondary origin resulting from differential chemical solution by ground waters circulating along some sort of a parting in hardened rock. (P. B. SE.)

**STYRENE** is a colourless, liquid, aromatic hydrocarbon, important chiefly for its marked tendency to undergo polymerization (*q.v.*). It was first produced commercially in 1935. Production thereafter increased steadily. Nearly all of it is used for synthetic rubber (see RUBBER), molded plastic materials (see PLASTICS), or synthetic resins (see RESINS). Styrene polymerizes slowly on standing, rapidly on heating, to form polystyrene, an inexpensive, clear, rigid plastic with excellent electrical and optical properties and with good strength and chemical resistance. Polystyrene is somewhat brittle; some of the copolymers of styrene are tougher.

Styrene was first found in storax balsam (Oriental sweet gum). It was isolated, analyzed, and named in 1839. It forms in the coking of coal and appears in small amounts in the crude xylene fraction. Styrene is produced by combining benzene (*q.v.*) from coal or petroleum with ethylene (*q.v.*) from the cracking of petroleum. The resulting ethylbenzene is then dehydrogenated to styrene. Styrene has the structure  $C_6H_5-CH=CH_2$ ; a boiling point of 293° F (145° C), a freezing point of -23.1° F (-30.6° C), a specific gravity at 77° F (25° C) of 0.904, and a refractive index of 1.544. Styrene has a burning taste and a sweetish, penetrating, aromatic odour like manufactured (coke-oven) gas, in which it is present in very small amount. The reactive double bond in styrene participates readily in chemical reaction with halogens, halogen acids, oxygen, and other reagents. See CHEMISTRY: *Organic Chemistry*.

(FR. R. M.)

**STYX**, in Greek mythology, one of the rivers of the underworld. The word *styx* literally means "hateful," and expresses loathing of death. In Homer the gods swear by the water of the Styx as their most binding oath, and this idea is elaborated in Hesiod's *Theogony*: Iris, the messenger of the gods, fetches water from the Styx which is poured out as a libation by the god concerned; if he perjures himself he is rendered insensible for a year and then banished from the divine society for nine years. Hesiod personifies Styx as the daughter of Ocean and the mother of Emulation, Victory, Power, and Might; she is described as an ally of Zeus in his struggle with Cronus.

In the classical period the Styx was identified with the stream now called Mavro Nero ("Black Water") near Nonacris in the Aroania Mountains (near modern Solos) in Arcadia, which plunges over a cliff into a deep gorge. Herodotus relates that Cleomenes I of Sparta attempted to found an Arcadian confederacy with oaths sworn by the water of Styx. According to popular superstition, the water of Styx was so poisonous that it would dissolve any vessel containing it except one made of a horse's hoof; there was a legend that Alexander the Great was poisoned by Styx water.

**SUAKIN** (SAWAKIN), once the major port of the Sudan, on the Red Sea coast in Kassala Province. It was abandoned in 1922, being replaced by Port Sudan, 36 mi. (58 km.) N. Pop. (1956) 4,228. Suakin was built on a coral island and connected by a causeway with El Geif, a suburb on the mainland. Because of the

enlargement of the coral reef the harbour entrance is no longer safe for large vessels.

Suakin seems to have started about the 12th century as a rival port to 'Aydhab (Aidhab), still known as Old Suakin, farther north, since merchants from Yemen and India could trade there with the Beja tribesmen without paying the Egyptian dues levied at 'Aydhab. Toward the end of the 13th century Suakin came under Egyptian control for some time. It increased in importance after the destruction of 'Aydhab c. 1428. The pilgrim route to Mecca has crossed the Red Sea between Suakin and Jidda, on the Arabian coast, ever since. In the 16th century, Suakin was occupied by the Turks, and by the 18th century its prosperity had seriously declined, although pilgrims continued to pass through it from Sennar, and there was still an export of slaves, gold, and ivory. In 1821 Mohammed Ali, after conquering Sudan, leased Suakin from Turkey. This lease lapsed at his death (1849), but in 1865 Ismail Pasha reacquired the port for Egypt and it remained in Egyptian hands during the Mahdist theocracy (1881-98; see MOHAMMED AHMED). Plans for its redevelopment as a major port were being considered in the 1960s. (A. J. AL.; I. C.)

**SUAREZ, FRANCISCO** (1548-1617), Spanish theologian and philosopher, most important figure (*doctor eximius et princeps*) of the second flowering of Scholasticism, and generally considered the greatest theologian of the Society of Jesus, was born in Granada on Jan. 5, 1548, to a family of jurists. He studied law in Salamanca and in 1564 joined the Jesuit order. After completion of his theological studies, he became (1571) instructor and professor of philosophy in Segovia, Valladolid and for a short time in Rome. From 1585 he taught theology in Alcalá and Salamanca. In 1597 he was appointed by Philip II professor *primarius* at Coimbra, where he died after a studious, yet humble and simple life, on Sept. 25, 1617.

Suárez' principal work in philosophy is the *Disputationes Metaphysicae*, in which he follows mostly Aristotle and Aquinas, yet taking in consideration the criticism of Duns Scotus and of late Scholasticism. He works out in some important points (*e.g.*, principle of individuation, potency and act) his own solution, and the points in which he departs from Thomism are considered by some scholars to be significant enough to warrant description as a separate system, called Suarezianism. The *Disputationes* was used for more than a century as the textbook in philosophy in most European universities, Catholic and Protestant alike, and Leibniz speaks of Suárez' philosophy as the *Philosophia recepta*. In theology Suárez intended to write a full commentary on the *Summa* of Thomas Aquinas in the form of treatises, but he did not succeed since, upon the request of his general and of Pope Paul V, he had to write apologetic works on the religious state (*De Virtute et Statu Religionis*, 1608-09) and a *Defensio Fidei* (1613) against Anglican theologians, the oath of supremacy and the divine right theory of James I. In the grand dispute on the efficacy of divine grace, free will and predestination he took a stand, in the system called Congruism (*De vera intelligentia auxilii efficacis*, 1605, published 1655), more with Luis de Molina against Domingo Báñez.

Suárez' treatises *De Legibus* (1612), *De Bello et de Indis* and the "Defense of the Faith" contain his political theory and legal philosophy, in which he is both most original and personal. He refutes the divine right theory and explains that the people itself is the original holder of political authority: thus all constitutions can only be of positive law, neither of divine nor of natural law; the state must be thought to come into existence (ideally) by the consent (social compact) of those forming it. He argues strongly for the natural rights of the human person such as life, liberty and property, and repudiates the Aristotelian thesis of "natural slavery," affirming that all forms of servitude are only of human positive law. He criticizes most of the practices of Spanish colonization in the newly discovered Indies. These lands are for him sovereign states, members of the community of nations legally equal to Spain. Neither pope nor emperor as supposedly lord of the world (an absurd theory to him) nor Christian princes have the right to order an invasion or to conquer these states by reason of the idolatry or supposed backwardness of their citizens or for the propagation of Christianity. This would be

against what Suárez calls for the first time the *jus inter gentes*, which, resting on natural law, contains customary and treaty law and, as the public law of the international community, is to be distinguished from the Roman *jus gentium*, which contained also private or civil law in addition to public law.

Suárez' collected works were published in 23 volumes at Venice (1740-51) and in 28 volumes at Paris (1856-78). Neither is complete; a complete and critical edition is in preparation.

Fichter, *Man of Spain* (1940); a full bibliography of and on Suárez is in *Atti del IV nascita di S.* (1949-50); Recasens Siches, *Legal Philosophy of Suárez*, in Spanish; H. Rommen, *Staatslehre des Suárez* (1927); J. Brown Scott, *Catholic Conception of International Law* (1934); G. Ambrosetti, *Philosophia delle Leggi di Suárez* (1950); Thomas U. Mullaney, *Suárez on Human Freedom* (1950). (H. A. Ro.)

**SUBDOMINANT**, in music, the 4th degree of the diatonic scale, as F in the scale of C. See **SCALE**.

**SUBIACO** (ancient **SUBLAQUEUM**), a town of Italy in Rome Province, Lazio region, on the Aniene River, 1,345 ft. (410 m.) above sea level and 45 mi. (73 km.) E of Rome. Pop. (1961) 8,595 (commune). Crowned by the Rocca Borgiana, originally built in the 11th century under Gregory VII, the town preserves its medieval form. Once a city of the Papal States, it has various buildings of Pius VI (who as cardinal was commendatory abbot), Gothic churches, mediæval icons, and a 14th-century bridge. Its ancient name recalls its position below the three Neronian lakes (the Simbruina stagna of Tacitus). In the remains of Nero's lakeside villa was found the headless statue of a youth kneeling (an Ephebe?), now in the Museo Nazionale Romano (Museo delle Terme) at Rome. An inundation destroyed the lakes in 1305. St. Benedict (q.v.) retired (c. 494) as a hermit to a cave, Sacro Speco (Holy Grotto), above the lakes. The church dedicated to St. Scholastica, St. Benedict's sister, first built in 981, was destroyed by an earthquake (1228) and rebuilt in Gothic style. The present Neoclassical church, within the Gothic one, is by G. Quarenghi. The German monks Arnold Pannartz and Conrad Schweinheim set up in Sta. Scholastica the first Italian printing press in the 15th century.

The convent of St. Benedict on a mountain slope has 9th-century frescoes in the Grotta dei Pastori (Grotto of the Shepherds). St. Benedict's cave and the lower church contain 13th-century frescoes. In the upper church are scenes from the life of Christ by the Siennese School. In St. Gregory's chapel is the first portrait of St. Francis of Assisi, probably painted before 1224.

Agriculture is the principal industry. There are also a paper mill, an establishment for making spectacles, and a stone quarry. (Gr. P.)

**SUBJECT**, in theory of knowledge and in psychology, means the knower or the perceiving mind or ego as opposed to the object of knowledge or sensation (see **KNOWLEDGE, THEORY OF**). In traditional logic (see **LOGIC: Traditional Logic**) the subject is that term (q.v.) of a categorical proposition that is distinguished from the predicate (see **CATEGORY; PREDICABLES**), as the "subject" of a sentence is in grammar.

**SUBJECTIVISM**, a philosophical term, applied in general to all theories that lay stress on the purely mental sides of experience, opposed to objectivism. In the narrowest sense, subjectivism goes to the logical extreme of denying that mind can know objects at all. Cf. **SOLIPSISM; IDEALISM; SKEPTICISM**. See also **AESTHETICS, HISTORY OF: The Subjective Approach; ETHICS: The Nature of Ethical Judgment; ETHICS, HISTORY OF: Ethical Relativity**.

**SUBMARINE**, a naval vessel capable of sustained operation underwater. Submarines first became a major factor in naval warfare during World War I (1914-18), when Germany employed them as commerce destroyers. They played a similar role on a larger scale in World War II (1939-45) in both the Atlantic and Pacific oceans. By the 1960s the nuclear-powered submarine capable of remaining underwater for months at a time and of firing medium-range nuclear missiles without surfacing had become a reality and was regarded by some naval strategists as the most potent of all naval weapons.

## HISTORICAL BACKGROUND

For centuries men attempted to find some way of descending beneath the surface of the sea for scientific observation, for salvage, or for attacking enemy ships in time of war. Herodotus, Aristotle, and Pliny the Elder all mentioned attempts to build diving bells or other such devices. The Greek mathematician and inventor Archimedes (c. 287-212 B.C.) laid the basis for a theoretical analysis of the matter by developing laws of floating bodies. A 13th-century French manuscript, "La Vrai Histoire d'Alexandre," describes an underwater venture by Alexander the Great (356-323 B.C.) in a glass barrel. Among the many inventions associated with the name of Leonardo da Vinci was a device for underwater exploration (see further **DIVING APPARATUS**). But significant progress in this area had to await two inventions that were not made until the latter part of the 19th century: the internal combustion engine for surface propulsion and the electric motor (powered by storage batteries) for underwater propulsion.

Not until 1578 does any record appear of a craft designed to be navigated underwater. In that year William Bourne, a British mathematician and author of books on naval matters, published *Inventions and Devises*, in which the "18th Devise" was the design of a completely enclosed boat that could be submerged and rowed underwater. It consisted of a wooden frame covered with waterproof leather. It was to be submerged by reducing its volume by contracting the sides through the use of hand vises. Because Bourne did not actually build such a boat, it is to Cornelis Drebbel (or Cornelius van Drebel), a Dutch inventor, that credit is usually given for building the first submarine. Between 1620 and 1624 he successfully maneuvered his craft during repeated trials in the Thames at depths of from 12 to 15 ft. beneath the surface. On one occasion King James I is said to have gone aboard the vessel and taken a short ride. Drebbel's craft resembled that proposed by Bourne in that its outer hull consisted of greased leather over a wooden frame. Oars extending through the sides and sealed with tight-fitting leather flaps provided a means of propulsion either on the surface or underwater. Drebbel built his first boat in 1620 and followed it later with two larger ones built on the same principles.

Submarine boats seem to have been numerous in the early years of the 18th century. By 1727 no fewer than 14 types had been patented in England alone. An unidentified inventor, whose work was described in the *Gentleman's Magazine* of 1747, proposed an ingenious method of submerging and surfacing his submarine. His design called for attaching a number of goatskin bags to the hull with each skin connected to an aperture in the bottom. He planned to submerge the vessel by filling the skins with water and to bring it to the surface again by forcing the water out of the skins with a twisting rod. This was the forerunner of the modern ballast tank.

It was during the American Revolution that a submarine was first used as an offensive weapon in naval warfare. The "Turtle," a one-man submarine invented by David Bushnell, a student at Yale, was built of wood in the shape of a pear and was hand-operated by a screw propeller. In 1776 it attempted to sink a British man-of-war in New York Harbor. It was operated at the time by an army sergeant, Ezra Lee of Lyme, Conn., who had volunteered to make the attempt. The plan was to have the "Turtle" make its approach to the ship underwater, attach a charge of gunpowder to the ship's bottom with a screw, and quickly leave the scene before the charge was exploded by a time fuze. After repeated failures to force the screw through the copper sheathing on the hull of HMS "Eagle," the submarine gave up, released the charge, and withdrew. The powder exploded without result, except that the "Eagle" at once decided to shift to a berth farther out to sea.

Although his name is most often associated with the invention of the steamboat, Robert Fulton experimented with submarines several years before he sailed the "Clermont" up the Hudson. In 1800, while Fulton was in France, he built the "Nautilus" in hopes of helping France to destroy the British fleet. Made of wood covered with iron plates and in the shape of an elongated oval, the "Nautilus" was somewhat similar in structure to the modern sub-

marine. A sail was provided for surface propulsion, and a hand-driven screw propeller drove the boat when submerged. A modified form of conning tower was equipped with a porthole for underwater observation, for the periscope had not yet been invented. Fulton tried to interest France, Britain, and the United States in his idea, but no nation ventured to sponsor the development of the craft, even though his model was superior to any submarine designed up to that time.

The first successful use of the submarine in war occurred in the American Civil War when the Confederacy developed a small type of semisubmersible vessel called "David." These were cigar-shaped craft, 50 ft. in length, steam-propelled, and carrying a crew of four. "Davids" were unable to attain complete submergence but cruised with the hatch and funnel exposed. Their armament consisted of a spar torpedo; i.e., an explosive warhead attached to a long pole extending ahead of the vessel. On Oct. 5, 1863, a "David" successfully attacked the Union ironclad "New Ironsides" in the harbour at Charleston, S.C. The spar torpedo was too light to sink the ironclad, but it caused considerable damage.

Encouraged by the success of this attack, the Confederacy authorized construction of a vessel that could submerge completely. Designed and built at Mobile, Ala., the craft was named "H. L. Hunley" in honour of its chief financial backer, Horace L. Hunley. Transported by railroad to Charleston, S.C., the "Hunley" on Feb. 17, 1864, operating on the surface at night, sank the Federal sloop "Housatonic" by means of a spar torpedo. The "Hunley" itself was lost in this action.

Interest in improvement of the submarine continued after the American Civil War, but the lack of a suitable means of propulsion continued to limit progress. In 1880 an English clergyman, the Rev. George W. Garrett, successfully operated a submarine with steam from a coal-fired boiler that featured a retractable smokestack. The fire had to be extinguished before the vessel submerged, but enough steam remained in the boilers for traveling several miles.

During this same period, a Swedish gun designer, Thorsten Nordenfelt, also constructed a submarine that used steam and was driven by twin screws. His craft could submerge to a depth of 50 ft. and was fitted with one of the first practical torpedo tubes.

One of the pioneers in submarine development, Wilhelm Bauer, a noncommissioned officer in the Bavarian artillery, built two boats, "Le Plongeur-Marin" (1851) and "Le Diable-Marin" (1855). The former came to an untimely end, but the latter, built for the Russian government, achieved a measure of success, making 134 dives before she was lost at sea. Her most notable exploit occurred in September 1856 at Kronstadt when Bauer submerged his vessel with a small orchestra on board. The underwater rendition of the Russian national anthem was clearly heard by all ships in the harbour.

In an effort to overcome problems of propulsion, two Frenchmen, Capt. Siméon Bourgois and Charles Brun, built a 146-ft. submarine, "Le Plongeur" (1864). Powered by an 80-hp. compressed-air engine, the vessel quickly exhausted her air tanks whenever she tried to go anywhere. Considerably more successful was a small (30 tons displacement) experimental submarine, ordered by the French Navy and designed in part by the Frenchman Gustave Zédé, called "Gymnote" (1886, launched 1888). It was propelled by an electric motor and was extremely maneuverable but tended to go out of control when it dived. It was followed by the "Gustave Zédé," designed by Zédé and Romazzotti the next year. This 270-ton vessel, after initial difficulties were overcome, proved highly successful. In 1892 G. Pullino made successful dives in the "Delfino." The "Nautilus" (1899) designed for France by Maxime Laubeuf was a double-hulled vessel propelled by steam on the surface and by storage batteries when submerged.

Electric power was the only suitable answer to the problem posed by underwater operation, and with this in mind an all-electric submarine, the "Nautilus," invented in 1884 by two Englishmen, Andrew Campbell and James Ash, was built in 1886. It was propelled at a surface speed of six knots by two 50-hp.

electric motors operated from a 100-cell storage battery. Because its battery had to be recharged and overhauled at short intervals its effective range never exceeded 80 mi.

Antedating these efforts were the experiments of an American, John P. Holland of New Jersey, who launched his first boat in 1875. Although his early models embodied features that were discontinued as development progressed, many of his original ideas, perfected in practice, came into later use. Outstanding in importance was the principle of submergence by water ballast and the use of horizontal rudders to cause the boat to dive. Not until 1895, however, did Holland, in competition with Nordenfelt, finally receive an order for a submarine from the U.S. government. This vessel, named the "Plunger," was propelled by steam on the surface and by electricity when submerged. The original craft was redesigned frequently during construction and was finally abandoned altogether in favour of a newer model then being built at Elizabeth, N.J. This was Holland's ninth submersible and the first to be delivered to the U.S. government. It was accepted by the U.S. Navy in 1900, named "Holland," and served as the model for submarines to follow. It was 53 ft. long, 10 ft. in diameter, and displaced 74 tons. For underwater propulsion it used an electric motor, and for cruising on the surface it was equipped with a gasoline engine. The British Navy soon ordered several Holland vessels, and the submarine won a place for itself in naval warfare. As a result, Holland is now generally recognized as the "father of the modern submarine."

Another American, Simon Lake, who began building submarines in 1894, designed them primarily with peacetime uses in mind. He equipped his vessels with an air lock that permitted a passenger in a diving helmet to emerge from the hull to walk about in the water and explore. His first model, the "Argonaut, Jr.," was solely an experimental one. It was built of two layers of yellow pine with a sheet of canvas between them and was operated by hand.

It was followed in 1897 by the "Argonaut," a cigar-shaped hull 36 ft. long and powered by a 30-hp. gasoline engine. This craft could submerge to the bottom of a lake or river and roll along the bottom on three wheels. When not in use, the wheels could be raised and carried in pockets in the keel. In 1898 the "Argonaut"

traveled under its own power through the heavy November storms from Norfolk to New York and was thus the first submarine to navigate extensively in the open sea. In 1906 Lake built the "Protector" and sold it to Russia. After it had successfully passed various severe tests there, Lake built a number of submersibles on contract for the Russian government. Thus the fundamental principles of construction and operation of submarine boats had been determined and demonstrated before the outbreak of World War I. By that time, too, internal-combustion engines, both gasoline and diesel, were available for use while the submarine was on the surface and could take in air freely. The invention of the periscope had materially increased the feasibility of underwater navigation (see PERISCOPE: *Submarine Periscopes*), and the primary weapon of the submarine, the torpedo, had been developed (see TORPEDO). Thus the preliminary development of the submarine was finished, and the vessel was ready to take its place as a major factor in naval warfare. See further *Submarine Warfare*, below.

### CONSTRUCTION FEATURES

While details of the construction of conventional submarines vary, the general principles of their design are similar. When a submarine rests on the surface, so little of it is seen above the water that it has the appearance of being longer and more slender than it really is. The typical U.S. submarine in World War II was 307 ft. long with a superstructure deck tapering almost to a point, both fore and aft, from its greatest width of approximately 16 ft. amidships. German and Italian submarines generally were smaller than those of the U.S. Navy while the Japanese were somewhat larger.

Beneath the superstructure deck is the all-welded hull, which actually consists of two hulls. Construction is on the basis of a cigar-shaped, watertight pressure hull subdivided into eight or more watertight compartments. Each compartment is a pressure vessel; that is, a watertight container or cylinder capable of withstanding great pressure. The pressure vessels, being subject to mechanical leverage, must be secured to one another by one common strength member (the keel) as well as by watertight connections (bulkheads).

In the double-hull type of submarine, the pressure hull is inside the outer hull; between the two hulls are the water and the fuel oil tanks. The pressure hull extends from the forward bulkhead of the forward trim tank to the after bulkhead of the after trim tank. Above the hull, and extending the length of the ship, is a non-watertight superstructure that forms the main deck for use when surfaced. A watertight tower (the conning tower) extending up through the superstructure amidships is characteristic of conventional submarines but on nuclear boats has been replaced by the "sail," which floods on submergence. When surfaced the submarine is operated from a bridge atop the conning tower or sail. Submerged navigation is carried on in the conning tower or in a compartment known as the control room directly below it. In submerged operation a periscope extending from the conning tower may be used for making observations.

A submarine is built to withstand the pressure of a head of seawater, consistent with requirements as shown by battle experience and with naval specifications. The pressure is measured in actual submergence tests from the surface of the water to the axis of the vessel through its pressure hull. Watertight bulkheads are designed structurally and strengthened through reinforcements to withstand the pressure at test depths.

In addition to the mechanisms required to operate it on the surface, a modern submarine contains operating machinery and tanks that enable it to dive, surface, and proceed submerged. The pressure hull houses most of the ship's machinery and armament and provides living quarters for the crew. It is divided into watertight compartments that are connected by watertight, pressure-resisting doors.

The main deck is attached to the exterior hull by means of the framing and rounded sides. Holes in the sides allow seawater to enter all hollow spaces in the superstructure and the deck when diving and drain off when the submarine is surfacing. The midship section of the main deck is occupied by the conning tower,

which is surmounted by the partially enclosed bridge "bubble," periscopes, and radar gear.

The bow is equipped with torpedo tube shutters and diving planes. The underside of the hull contains ballast tanks, flooding ports, and underwater soundheads for sonar and the fathometer. It may also contain a mushroom anchor recessed into a housing on the bottom.

The principal ballast in a submarine is water. The main ballast tanks make possible the controlled diving and surfacing of the vessel. When a submarine is on the surface the tanks are empty, and when it is submerged they are completely full. To flood the tanks rapidly there are large, power-operated vents at the tops of the tanks, and the tank bottoms are generally open to the sea, although some have large power-operated flood valves. The power for operating the vents (and flood valves, if installed) is usually hydraulic, although pneumatic equipment has been used.

To cause a submarine to dive, all vents (and flood valves, if fitted) are opened, allowing the trapped air to escape and seawater to enter the tanks. This has the effect of reducing the displacement of the submarine from that of the outer hull to that of the pressure hull. After leveling off at the desired depth, and ascertaining that the ballast tanks are completely flooded, the vent valves are usually closed. The submarine is then ready to be brought to the surface at any time by directing high-pressure air into the tanks and expelling the water.

To keep the submarine in a state of neutral buoyancy, trimming tanks are provided to compensate for changes in weights due to the consumption of food, ammunition, and fuel. One or more of these tanks are located approximately amidships and are used to control overall weight. The forward and after trimming tanks are used to correct any alteration in the longitudinal distribution of weight. These tanks are equipped with remote reading gauges, and the trimming system is designed to provide the greatest flexibility in shifting water ballast. There is also a negative buoyancy tank which, when flooded, permits the submarine to remain motionless on the sea bottom. It is also used in crash dives to enable the submarine to dive or gain depth quickly.

"Water around torpedo" tanks are fitted below the torpedo tubes and contain sufficient water to fill the spaces around the torpedoes when in the tubes. The torpedoes can thus be left dry in the tubes and can readily be withdrawn for examination. When it is desired to fire a torpedo, the tube is closed and the water from the "water around torpedo" tanks is blown into the tube; when the outer door of the tube is opened, no seawater enters because the tube is already full, and the weight of the submarine is unaltered.

The importance of air systems to a submarine cannot be over-emphasized, for virtually every function in the diving and surfacing procedure is performed by air provided by one or more of the air systems. The main hydraulic system, for example, operates because of the air pressure maintained in the air-accumulator flask; torpedoes were formerly discharged by air pressure, and the diesel engines were started by air. Compressed air is necessary for the submarine to surface, submerge, attack, and cruise. Compressed air with oxygen added is used to revitalize the air in the ship after long periods of submergence. Compressed air is stored in tanks and is supplied by compressors located in the pump room, a cellarlike compartment located directly beneath the control room. Compressed air can be obtained also from a tender ship through outside connections.

A submarine is designed so that it can be kept under complete control while it dives or surfaces rapidly; it must be able to proceed on the surface or to submerge to specific depths at the desired rate of speed. To do so quickly and efficiently, it must maintain fore-and-aft balance by controlling the amount and distribution of water in the various tanks used for this purpose. Motor-driven pumps are provided for pumping out the submarine's tanks or bilges; they are capable of pumping against the water pressure at whatever depth the vessel is designed to reach and are also capable of pumping certain ballast tanks in case of compressed air failure.

The rudder of the submarine is similar to that of any surface vessel. Under normal operation the steering system has its own

source of electrohydraulic power. The principal control units are assembled in the steering stand, located in the control room. To provide for every contingency, the steering system is planned so that three different methods of steering are available, based on three different sources of hydraulic power.

The hydroplanes, or bow and stern planes, which are actually horizontal rudders, are used for depth and angle control of the submarine when operating submerged. They are shaped like stubby aircraft wings and can be turned through 35° either up or down. The after pair, when in a neutral position, give the submarine a certain stability. The forward pair can be folded into the side of the superstructure; this decreases the water resistance, and the planes are not subject to additional strain when on the surface. The bow planes assist in submerging the vessel by overcoming the slight amount of buoyancy carried by the submarine when the negative buoyancy tank has not been flooded.

**Armament.**—Torpedoes were the main weapons of nonnuclear submarines. U.S. submarines had a maximum of ten 21-in. torpedo tubes and carried as many as 24 torpedoes. The tubes were arranged horizontally fore and aft and could be loaded from within the submarine. Each tube was fitted with doors at both ends so that the inner door could be opened when the outer door was closed, and vice versa. The tubes could be fired electrically or by hand when the submarine was on the surface or submerged. Submarine mines could also be laid through torpedo tubes.

Many advances in torpedoes after World War II greatly extended the capabilities of even the conventional submarine. In addition to magnetic and acoustic homing torpedoes, both widely used in World War II, experiments were made in combining rockets with torpedoes, so that a torpedo fired underwater would come to the surface, ignite its rocket engine, and fly some miles through the air before once again entering the water to seek out its target. (See further TORPEDO.)

**Periscopes.**—The periscope is the eye of the submarine. It was invented and developed to enable the submarine to view the surface without detection by surface craft. While it is basically simple in principle, it is a complicated piece of apparatus. The earliest submarines were built without provision for periscopes and when submerged were forced to grope their way blindly. In 1854 E. H. Marié-Davy, a Frenchman, designed a submarine sight tube containing two mirrors, one above the other, held at a 45° angle and facing in opposite directions. These mirrors provided some degree of sight to the submerged vessel but they were faulty at best, and in 1872 prisms were substituted for mirrors.

The essential function of a periscope is to give the person conning the submarine a view of the surface of the water while the vessel remains submerged. The instrument used on U.S. submarines is a 40-ft. tube about 7½ in. in diameter, although the upper part tapers to a little more than one inch in diameter. It is equipped with a tilting head prism capable of elevating the line of sight 74.5° above the horizon and of correcting for the roll or pitch of the vessel. The most modern periscopes have an optical system that revolves independently of the casing, permitting the observer to remain in one position rather than moving around to scan the horizon. Periscopes may be fitted with camera attachments for photographic reconnaissance or with a periscope sextant for purposes of celestial navigation. See further PERISCOPE.

### PROPULSION SYSTEMS

**Diesel-Electric Propulsion Systems.**—The first U.S. submarines utilizing internal-combustion engines for propulsion were powered by 45-hp., two-cylinder, four-stroke-cycle gasoline engines produced by the Otto Company of Philadelphia, Pa. Early British submarines made use of 12- and 16-cylinder gasoline engines. The hazards accompanying the use of such a highly volatile fuel as gasoline were quickly realized. Stowage was a constant problem, and handling the fuel was extremely dangerous. Internal explosions were frequent; many of the engines gave off considerable carbon monoxide gas that was a menace to personnel. Because of the drawbacks associated with gasoline engines, the German firm Maschinenfabrik Augsburg-Nürnberg A.-G. (MAN) built and experimented with two-stroke-cycle diesel engines for submarine

propulsion. However, insufficient progress had been made in metallurgy to provide metals capable of withstanding the greater heat and stress inherent in diesels. MAN then turned its efforts toward production of a four-stroke-cycle diesel engine capable of developing 1,000 hp. While fairly successful, these engines eventually developed structural weaknesses at the crankcase. Prior to 1930 the engines used in most submarines of all the larger naval powers with the exception of Great Britain were four-stroke-cycle diesels. The U.S. Navy, however, experimented with a two-stroke-cycle Busch-Sulzer engine and equipped a number of boats with this type. The U.S. Navy also turned to the use of solid-injection engines, with their advantage in weight reduction.

Along with the development of these engines there was experimentation in the method of transmitting the power of the engine to the propellers. Originally, engines were coupled to the propellers through friction clutches. With the advent of high-speed engines came reduction gears to keep propeller speed in an efficient range, and the mechanical clutch was replaced by electric drive. The power developed by the engine-driven generators was used in the two main motors for surface propulsion, or for charging batteries. The conventional submarine is usually driven by four main diesel engines, each capable of producing 1,600 hp. The four main generators each produce 1,100 kw. There are four slow-speed motors, driven by the generators or batteries, each producing about 1,375 hp. The auxiliary engine is rated at 450 hp. and drives a 300-kw. generator.

**Batteries.**—When submerged the diesels and generators cannot be used because they require a great deal of fresh air and a means of expelling exhaust fumes. Power for the motors is therefore supplied by storage batteries, which are recharged by the generators during surface operations.

Most older U.S. submarines have two main storage batteries of 126 cells each. Usually, the forward battery is installed below-decks in the area of the wardroom while the after battery is located in the crew's space. Each cell weighs approximately 1,650 lb. Each battery is fitted with an exhaust ventilating system to remove battery gases and hydrogen that develop when the batteries are being recharged.

### ANCILLARY DEVELOPMENTS

**Escape Apparatus.**—For many years there were three vital pieces of gear used in escaping from a submerged submarine. The first of these, the marker buoy, was released by a disabled submarine to assist in guiding rescue parties to the area where the boat rested. If a properly equipped rescue party was able to locate the submarine, a second piece of gear, a rescue chamber, was lowered by cable over an escape hatch and the crew members of the submarine were removed in relays to the surface. However, if rescue parties were unable to locate the submarine, individual ascent was necessary. For many years this ascent was made with the assistance of an artificial lung of which the two main types were the Davis submerged escape apparatus, used by the British and the Momsen lung, used by the United States. By the mid-1950s, however, the use of these lungs was abandoned by both British and American navies in favour of a buoyant ascent, in which the escapee is assisted only by a life jacket. As he begins his ascent, the escapee exhales all the air he can from his lungs and continues to exhale all the way to the surface. So long as he is exhaling, he is not subject to decompression "bends."

**Snorkel and Guppy.**—In the latter part of World War II the Germans adopted a radical change in submarine design known as the schnorkel—a Dutch invention. The spelling was reduced by the Americans to snorkel and further changed by the British to snort. The snorkel is a breathing tube that is raised while the submarine is at periscope depth; air for the diesels can thus be obtained from the surface. The snorkel enables the submarine to cruise on its diesel engines while almost totally submerged and to conserve its battery power for attack and evasive maneuvers.

At the end of World War II the United States Navy developed the guppy submarine, the name standing for "greater underwater propulsion power." It had the same type hull as the fleet-type submarine of World War II but the superstructure was radically

modified by reducing the surface area and streamlining every protruding object. The lifelines and all guns were removed, the bitts were made retractable, and the periscope supports were enclosed in a streamlined metal fairing. The submerged speed of the new guppy was considerably greater than that of the fleet-type boat and nearly twice that of the old-style submarines.

**Developments After World War II.**—The lessons of World War II wrought great changes in submarine construction. Torpedoes came to be fired by hydraulic (water) pressure instead of compressed air as previously, eliminating any chance of telltale air bubbles escaping to the surface and betraying the submarine's location. Hulls were given greater strength for deeper diving. Hydraulic mechanisms (oil) were extensively employed throughout the ship for quieter and more efficient operation. Radar and sonar equipment increased in importance as it contributed to efficient operation. Torpedoes no longer had to be fired with sharp-shooting accuracy; fire-control equipment and homing torpedoes (the torpedo that seeks its target) eliminated much of the guesswork and chance in firing torpedoes. Engines, electrical motors, and generators were made more compact.

During World War II, the Germans had conducted extensive experiments on the Type XXVI U-boat (the Walther boat), driven by a closed system of combustion that could be operated underwater by employing liquid hydrogen peroxide rather than air to supply the oxygen for fuel combustion. This system would permit greater submerged speed by allowing the use of the more powerful diesel engines while the submarine was completely submerged. Technical difficulties prevented this type of submarine from becoming operational during the war. After the war the German designs were revised and adapted by several navies, culminating in the development of the experimental British HMS "Explorer," accepted into service in 1956. In spite of the success of the "Explorer," the hydrogen-peroxide type was, generally speaking, obsolete by the time it was operational because of the development of the nuclear submarine.

Because World War II had shown that midget submarines had some value, several navies continued the development of this type. Probably the most extensive work was done by the British. Most midget submarines were about 50 ft. in length and carried a crew of five officers and men. Some carried as armament, in place of, or in addition to, torpedoes, limpet mines that were intended to be attached to the hulls of enemy vessels until detonated.

### NUCLEAR SUBMARINES

On Jan. 17, 1955, the USS "Nautilus" made history by getting underway on nuclear power. Here at last was the true submarine. The "Nautilus" could maintain submerged speeds in excess of 20 knots almost indefinitely, limited only by the endurance of her

crew and her supply of provisions. The ship's air-conditioned interior was designed for the greatest possible comfort of the crew. Air was filtered and recirculated through carbon-dioxide scrubbers, and oxygen was added as required.

The power plant of a nuclear submarine consists of an atomic reactor that generates enormous heat. The reaction is controlled by inserting control rods into the core or removing them. When the rods are fully inserted the reaction stops, and when they are completely withdrawn the reaction is at its maximum. Surrounding the reactor core is a primary coolant, water pumped past the core by coolant pumps. The heated water of the coolant is forced into a boiler-heat exchanger. Since the coolant water is radioactive, it cannot be used directly in the propulsion system, so its heat is transferred to uncontaminated water on the secondary side of the boiler-heat exchanger. This uncontaminated water is thereby converted to steam, which passes through a control valve into the engine room where it is used to drive the ship's service turbogenerator (SSTG), the coolant turbogenerator (CTG), and the propulsion turbines. From there it passes through condensers into the feed water system. The water circulation on the reactor side (known as the primary system) is thus completely isolated from the propulsion side (the secondary system), so that no transfer of radioactivity takes place. On most nuclear submarines, reduction gears are used between the turbines and the shaft; others incorporate turbo-electric drive.

In the event of reactor failure, nuclear submarines are equipped with auxiliary electrical propulsion that can receive power from batteries, small diesel engines, or motor generators. Precautions against radioactive contamination of the vessel and exposure of the crew are so extensive that in a year's cruise crew members receive less than that set by the Bureau of Standards as the permissible radiation for a single week.

**Nuclear Submarine Developments.**—Experiments with the "Nautilus" and with the conventionally propelled experimental submarine USS "Albacore" led to great advances, both in power plant design and in hydrodynamics. The "Albacore," which was specially designed for hydrodynamic research, reached submerged speeds far in excess of any earlier submarine. Lessons learned from her design were adapted to the "Skipjack" class of attack

BY COURTESY OF U.S. NAVY

USS "TRITON," TWIN-REACTOR NUCLEAR SUBMARINE WHICH IN 1960 BECAME THE FIRST SUBMARINE TO ENCIRCLE THE GLOBE WITHOUT COMPLETELY SURFACING

nuclear submarines, and to some extent to all subsequent nuclear submarines. Other navies also worked to develop undersea nuclear craft. The Soviet Union built an undisclosed number of nuclear boats, and in 1963 Great Britain commissioned her first nuclear submarine, HMS "Dreadnought," perpetuating a distinguished name in the Royal Navy.

With nuclear propulsion, the development of atmosphere regeneration systems, and advances in the strength of pressure hulls, submarines increased their ranges of operation, design, and capabilities. During the period from Aug. 1-5, 1958, the "Nautilus," under the command of Comdr. William R. Anderson, made the first submerged polar transit from Point Barrow, Alaska, to the Greenland Sea, traveling 1,830 mi. under the polar ice cap. She crossed the geographic North Pole on Aug. 3. Several other submarines duplicated this feat, and some surfaced at the Pole. The USS "Triton," the world's largest submarine (at time of building) and the only one equipped with two reactors, on May 10, 1960, completed the first submerged circumnavigation of the world, following roughly the route taken by Magellan's fleet (1519-22). On this historic voyage she was commanded by Capt. Edward L. Beach.

The depth to which submarines can descend and their speed underwater are military secrets. Many U.S. submarines of the World War II variety could descend to 500 ft. and attain surface speeds greater than 20 knots. It was assumed that nuclear submarines in service in the 1960s could descend to greater depths and attain higher submerged speeds. When operating at such depths the submarine, of course, cannot use its periscope, radio, or radar, for they require operation at or near the surface.

Most nuclear submarines have been designated "attack submarines" and are designed to carry on the submarine's conventional role of destroying surface ships and other submarines. The USS "Tullibee" was especially designed as an antisubmarine submarine, and the USS "Halibut" was designed to fire the guided missile Regulus from the surface against either sea or land targets.

**Polaris Submarines.**—The most significant advance in the strategic employment of the submarine came about with the building of the Fleet Ballistic Missile (FBM) Polaris submarines in the 1960s. Each of these submarines could carry 16 Polaris solid-propellant, intermediate-range ballistic missiles, which could be fired when the submarine was completely submerged. The first successful firing of a Polaris missile from a submerged submarine, the USS "George Washington," occurred on July 20, 1960. Compressed air was used for the launching at that time, but later submarines employed steam-powered launchers. All of the 16 missiles could be fired in the short span of 15 minutes. The first Polaris missiles had a range of up to 1,200 mi., but this range was increased with the Polaris A-3 to more than 2,800 mi. Polaris submarines were kept almost continually at sea during the 1960s, two complete crews being designated for each one, so that at the end of a patrol of up to 60 days, the submarine could enter port, exchange crews, and depart again in a very short time. To insure communication with Polaris submarines at sea, powerful, ultra-low frequency radio transmitters were used so that the signals could be

detected while the submarines were under water. Since pinpoint accuracy in plotting the vessel's position is essential for firing the missiles, highly improved navigational methods were developed, including a device known as SINS (Ship's Inertial Navigation System). Elaborate safety precautions were taken to prevent accidental or deliberate but unauthorized firing of the missiles.

The first Polaris submarine to enter service was the USS "George Washington," which sailed on its first patrol in November 1960. It was the first of five submarines of its class. Be-

ginning with this vessel, the U.S. Navy modified its traditional practice of naming submarines for fish; all Polaris submarines were named for persons famous in American history, among them Patrick Henry, Robert E. Lee, and Theodore Roosevelt.

The "Ethan Allen," launched in November 1960, was the first of five additional Polaris submarines that were larger (6,900 tons standard displacement as compared with 5,600 tons for the "George Washington") and of a new hull design. The "Lafayette," first of its class of 31, was launched in May 1962. Submarines of this class were the largest of all U.S. submarines—7,250 tons standard displacement and 425 ft. in length.

The development of the Polaris submarine revolutionized the strategic role of the submarine. Its primary mission was no longer the destruction of enemy ships but the launching of nuclear missiles at land targets far inside the enemy's borders. Because the Polaris submarines could cruise for long periods underwater and launch missiles without surfacing, they constituted mobile missile launching platforms that were virtually undetectable. Nuclear submarines experienced a serious setback in April 1963 when the USS "Thresher" sank, with the loss of all on board, about 200 mi. off the New England coast while undergoing deep submergence tests. The cause of this disaster—the first for an atomic submarine and the worst disaster in submarine history—was not determined.

By the 1960s the Soviet Union had apparently stabilized its submarine fleet at approximately 475 boats, retiring older vessels as new ones came into service. The United States had over 200 submarines, of which about two-fifths were of post-World War II construction, and half of those nuclear. The third largest submarine power, Great Britain, had 65 submarines, including 20 built since World War II. France and Sweden, each with about 30 submarines, also had significant submarine forces. (H. H. A.)

## SUBMARINE WARFARE

Submarine warfare is a relatively new form of naval warfare dating essentially from World War I (1914-18) and in this respect paralleling the history of air warfare and tank warfare. It was made possible by the technological development during the early years of the 20th century of the submarine itself and of the periscope, torpedo, and radio. The submarine gained greater stature as a strategic weapon in the 1950s and 1960s when nuclear power was successfully adapted for submarine propulsion and when means were devised for launching, from a submerged position, guided missiles capable of carrying nuclear warheads to targets 2,800 mi. away.

**World War I.**—Early in the 20th century France led in the development of submarines but it was Germany that first employed them in war as substitutes for surface commerce raiders. (For the legal aspects of this matter, see LAWS OF WAR: *Conduct of Hostilities*.)

At the outset of World War I, German U-boats, though numbering only 28, achieved notable successes against British warships but because of the reactions of neutral powers (especially the United States) Germany hesitated before adopting unrestricted

submarine warfare against merchant ships. The decision to do so in February 1917 was largely responsible for the entry of the United States into the war. The submarine campaign then became a race between German sinkings of merchant ships and the building of ships, mainly in the United States, to replace them. In April 1917, 430 Allied and neutral ships totaling 852,000 tons were sunk, and it seemed likely that the German gamble would succeed. However, the introduction of convoys, the arrival of numerous U.S. destroyers, and the vast output of American shipyards turned the tables. By the end of the war Germany had built 344 U-boats and had 226 under construction. The peak U-boat strength of 140 was reached in October 1917, but there were never more than about 60 at sea at one time. This comparatively small number of submarines accounted for nearly 90% of Allied shipping losses. The armistice terms required Germany and Austria to surrender all their U-boats, and the Treaty of Versailles forbade them to possess submarines in the future.

Because the German and Austrian surface warships were confined within the North Sea and the Adriatic Sea, respectively, and their merchant shipping was quickly swept off the seas, Allied submarines could never find plentiful targets. But British submarines penetrated into the Baltic in 1914-15, and into the Sea of Marmara during the Gallipoli campaign of 1915. In both cases a few submarines caused considerable disruption of supply traffic.

Submarines employed three types of weapons in World War I—the torpedo, the mine, and the gun. The torpedo was the submarine's natural weapon, for it could be launched while the submarine was fully submerged and was approaching its target unobserved; minefields could also be laid in the same stealthy manner. But to use its guns a submarine had to come to the surface where it was at a disadvantage against surface warships or armed merchantmen because it lacked protective armour and carried only a few small deck guns. At the very beginning of World War I submarines used gunfire against merchantmen but when the latter were armed the U-boats preferred not to face them, for the merchantmen usually mounted more powerful guns. (For antisubmarine operations *see* below.)

**World War II.**—At the end of World War I the lessons of the submarine campaign were well understood in the British and U.S. navies; but nonetheless they were gradually forgotten. Even after Germany had repudiated the Treaty of Versailles and had negotiated the right to build submarines up to the total British strength in 1935, it was believed that Germany would honour its signature of the London Protocol of 1936, whereby submarines were bound to conform to the established rules of international law. Thus Britain was ill prepared in 1939 for a resumption of unrestricted submarine warfare, and during the early months of World War II the U-boats, which at that time numbered only 57, again achieved great successes. The first phase, during which the U-boats generally operated singly, ended in March 1941, by which time many merchant ships were sailing in convoy, trained escort groups were becoming available, and aircraft were again

proving their effectiveness as antisubmarine weapons. In the next phase the Germans, having acquired air and submarine bases in Norway and western France, were able to reach much farther out into the Atlantic, and their submarines began to operate in groups (called wolf packs by the British). One U-boat would shadow a convoy, summon others by radio, and then the group would attack, generally on the surface at night. These tactics succeeded until radar came to the aid of the escorts, and until convoys could be given continuous sea and air escort all the way across the Atlantic in both directions. In March 1943, as in April 1917, the Germans nearly succeeded in cutting Britain's Atlantic lifeline, but by May escort carriers and very-long-range reconnaissance bombers became available. After the U-boats lost 41 of their number during that month they withdrew temporarily from the Atlantic.

In the next phase U-boats were sent to remote waters where unescorted targets could still be found. Although at first they achieved considerable successes, especially in the Indian Ocean, the Allied strategy of striking at the U-boats' supply vessels and putting all possible shipping into convoy again proved successful. In the final phase the U-boats, then fitted with the schnorkel (snorkel or snort) breathing tube, which greatly reduced the effectiveness of radar, returned to the coastal waters around the British Isles; but they sank few ships and themselves suffered heavy losses.

Italian submarines, which numbered 115 in June 1940, had little influence on the Mediterranean campaigns. But when in 1941 the Germans sent U-boats into the Mediterranean, they sank a number of major British warships and offered a serious threat. Not until mid-1944 were U-boats mastered in the Mediterranean. British submarines, mostly based on Malta, did much to sever Axis sea communications with North Africa, but at a heavy price, 50 of them being lost.

In the Pacific the considerable Japanese submarine force (63 boats in December 1941) was deployed against major warships. Despite the dependence of the Allies on a long line of sea communications between the United States and the south Pacific the Japanese never organized a sustained attack on merchant shipping; nor did a brief cooperation with German U-boats in the Indian Ocean in 1942 yield significant results. The United States strategy was the precise opposite of the Japanese, and from the outset the U.S. Navy made Japanese seaborne traffic a major objective. Nor was this campaign inhibited by tender considerations regarding the legality of such attacks, for Germany and Italy, reluctantly followed by Britain, had already adopted what was in fact unrestricted submarine warfare. Moreover, by its vast industrial capacity the United States could easily outbuild Japan in submarines as in all other war supplies. Between 1942 and 1945 the U.S. Navy commissioned 205 new submarines, 170 being of the splendid "Fleet" type capable of prolonged patrols in distant waters. Furthermore the development of new weapons and equipment gave the U.S. submarines a decisive advantage, and Japanese failure to defend seaborne traffic by an organized convoy system contributed to the U.S. success. The U.S. Navy's submarines, which sank 1,153 Japanese merchant ships totaling 4,889,000 tons (57% of all Japanese losses), were the principal instrument of the blockade which, together with the defeat of Japan's main fleets in the series of major battles fought between April 1942 and October 1944, contributed greatly to bringing about the Japanese collapse and surrender.

In World War II Germany built 1,162 U-boats, of which 785 were destroyed and the remainder surrendered (or were scuttled to avoid surrender) at the capitulation. Of the 632 U-boats sunk at sea, Allied surface ships and shore-based aircraft accounted for the great majority (246 and 245 respectively). The submarine losses of the other belligerents were much smaller than those of Germany, totaling 74 British, 52 U.S., 84 Italian, and 127 Japanese. As in World War I, submarines inflicted by far the greatest proportion of all Allied shipping losses. Although U.S. warships and aircraft accounted for the great majority of Japanese submarines destroyed, it was Britain that bore the main burden of the second (as of the first) campaign against German U-boats. British

GERMAN U-BOATS USED IN THE EARLY PART OF WORLD WAR II

naval and air forces sank 500 of the 632 U-boats sunk at sea, and more than three-quarters of the Allied merchant shipping destroyed came from the British merchant navy.

**Antisubmarine Operations.**—Many countermeasures were developed to defeat the submarine. Camouflage paint was used in World War I to render surface ships less visible or to distort their appearance and make it more difficult for the submarine to determine the target's course and speed, factors essential to successful torpedo fire. Steaming on a zigzag course also tended to confuse submarines. But camouflage and zigzagging were of limited value, for a ship might turn toward a submarine instead of away from it, and certain weather conditions might make camouflage paint stand out at great distances and actually attract submarines. Both camouflage and zigzagging were passive defense measures; more important were the active defense measures such as the use of depth charges, the practice of convoying ships, bombing submarine bases, and developing detection devices.

The primary antisubmarine weapon in both world wars was the depth charge (depth bomb in the U.S. Navy) which was operated hydrostatically and could be set to detonate at various depths down to 750 ft. Initially it could be dropped or fired only from surface ships, but in World War II it was adapted for use by aircraft. A ship attacking a submarine would endeavour to place a pattern of depth charges around it. But because a submarine could fairly easily evade an attack made by a single ship, in World War II it became normal for several ships to make coordinated attacks. The directing ship maintained asdic (sonar) contact continuously and signaled to the others when they reached the correct position to release their depth charges. This made it much more difficult for a submarine to avoid the pattern. Because aircraft could attack a submarine only on or near the surface they used a special shallow-firing depth charge. Antisubmarine contact bombs were developed by the British between the wars but proved ineffective. Other antisubmarine weapons are the torpedo (especially when fired from another submarine), the mine, and the guns of surface ships. Ramming was also used quite frequently against surfaced submarines in both world wars; but the toughness of a submarine's pressure hull was such that a lightly built antisubmarine vessel could incur severe damage from ramming, and the practice came to be discouraged. Mines proved an effective deterrent to submarine operations in waters shallow enough for minelaying, such as the Straits of Dover and the Malta Channel, and destroyed many submarines. Harbours and narrow channels were in some cases defended against passage by submarines by a detection device ("indicator loop") laid on the seabed. The loop indicated the passage over it of a steel vessel, enabling a controlled minefield to be fired from a shore station. Obstructions such as booms and nets were also placed across harbour entrances.

**Escort and Convoy.**—Strategically it was as commerce raiders that submarines exerted most influence in both world wars. However, they also achieved important successes against large warships, hence the mere threat of their presence compelled surface fleets to adopt constant antisubmarine escort. For this reason the torpedo-boat destroyer of World War I became, as the destroyer of World War II, primarily an antisubmarine vessel; other vessels such as frigates (destroyer escorts in the U.S. Navy), sloops, and corvettes were designed chiefly for the antisubmarine role. The world wars proved that a comparatively few submarines can force on the enemy a disproportionate effort in the provision of such vessels.

Much the most effective antisubmarine strategy was the adoption of escorted convoys (see *Convoy*). A submarine must approach the convoy to attack it, and it thus affords the escorts an opportunity to strike back. Apart from the merchant ships they saved by this strategy, the convoy escorts were among the most effective submarine killers. In World War I the British opposed convoy, taking an exaggerated view of its difficulties. It was not adopted until losses of merchant ships became catastrophic in 1917; it then quickly proved effective. In World War II convoy was introduced without delay by both Britain and the United States; but Japan delayed the adoption of convoy until it was

too late to prevent disastrous losses. Sea and air patrols and hunting groups, though frequently tried in both world wars, were much less effective than convoy escorts as submarine killers. In World War I the British deployed disguised merchantmen (Q-ships) on trade routes to lure U-boats within range of their concealed armament. They achieved a few successes, but the Germans soon became wary. The reintroduction of Q-ships by the British early in World War II was a total failure.

Both airships and airplanes were introduced for convoy escort toward the end of World War I. Though aircraft sank no U-boats in that war, their influence on the campaign was substantial. Aircraft could give early warning of a U-boat's presence and by forcing it to submerge they greatly reduced its effectiveness. In World War II air convoy escorts from aircraft carriers and from airfields made a decisive contribution. In the same conflict operational research was applied to antisubmarine warfare by Britain and the United States to furnish assessments of the optimum size of convoys, the speeds below which merchant ships should not be sailed independently, and the effectiveness of air escorts.

**Bombing Submarine Bases.**—In World War I, bomber aircraft were occasionally employed against U-boat bases, though without significant results. In World War II, a big effort was devoted by the RAF and USAAF to attacking U-boat bases, building yards, and associated factories. The Germans, however, mitigated the effects by dispersing production and by prefabricating U-boats, while in the operational bases they constructed enormously strong concrete pens to protect their U-boats. Strategic bombing undoubtedly delayed U-boat production, but not until the German air defenses finally collapsed were considerable numbers of completed U-boats thereby destroyed.

**Sonar and Radar.**—Detection has always been the cardinal problem in antisubmarine warfare, and evasion of detection the primary aim of the submarine. In World War I detection was possible only by visual sighting or by hydrophones; and the latter (capable of indicating approximate direction but not distance) were ineffective if other ships were nearby. But the development of the asdic (later sonar) ultrasonic detector in the 1920s greatly reduced the submarine's capacity for concealment. Unfortunately it also led in Britain to a belief that the submarine had been mastered. Moreover, between the wars naval establishments neglected to develop antisubmarine weapons with a performance to match the improved methods of detection. In World War II all submarines, as well as antisubmarine vessels, were fitted with sonar. But the most important antisubmarine development of the period was the shortwave (10 cm.) radar that enabled ships and aircraft to detect a surfaced submarine at a range of about 2,000 yd. Radar virtually eliminated the need to rely on sighting and deprived the submarine of its immunity from attack during darkness—the period when the submarine customarily moved on the surface and recharged its batteries.

**Controlling Antisubmarine Operations.**—In World War II the Royal Navy developed the control of antisubmarine operations to a fine art; the U.S. Navy adopted the same principles. The system was based on the centralized collection of intelligence, especially from the enemy's radio traffic. Widely separated direction-finding stations intercepted enemy signals, measured the bearing of the transmitting submarine, and signaled the bearings to the operational centre, where the resulting position was related to other intelligence. Orders to search were then sent to forces in the vicinity, and any convoys that appeared to be imperiled were diverted. Ship-mounted high-frequency direction-finding (H/F D/F) radio much improved the efficiency of the system, and a submarine's position could often be accurately plotted within seconds of its sending a message.

The potentialities of the submarine in an antisubmarine role were appreciated in World War I, but not until World War II were they fully exploited. Allied submarines then sank 21 U-boats, 18 Italian and 28 Japanese submarines.

**Ancillary Employment of Submarines.**—In both world wars submarines were frequently used in conjunction with the main fleets for reconnaissance and shadowing. Also they were used to supply beleaguered garrisons, notably by the British during

the siege of Malta (1941–43) and by the Japanese during the Solomon Islands campaign (1942–43). But such employment is a diversion from the submarine's offensive role and was adopted only as an emergency measure. In World Wars I and II Germany used U-boats to pass strategic cargoes through the British blockade. Submarines were also used, especially by the British in World War II, as instruments of irregular warfare, such as landing agents or raiding parties.

**Minisubmarines.**—The use of small submersible craft for attacking ships in harbour was pioneered by the American David Bushnell in 1776 and continued by the Confederates in the American Civil War, but with little success in either case. Toward the end of World War I an Austrian battleship was sunk in Pola Harbour by an attack of this kind. In World War II, Britain, Germany, Italy, and Japan developed a variety of midget and pigmy submarines. Although they scored a few outstanding successes, such as the crippling by Italian frogmen of two British battleships in Alexandria harbour in December 1941 and the severe damage caused to the German battleship "Tirpitz" in a Norwegian fjord by British X-craft (4-man midget submarines) in September 1943, it is doubtful whether the results justified the considerable effort devoted to producing them.

**Developments After World War II.**—The profound influence of the submarine in World War II and the increased vulnerability of surface warships to air attack compelled maritime powers thereafter to foster developments in underwater warfare. Indeed, after 1945 the prevailing naval attitude toward the submarine, which only 25 years earlier had been deemed the weapon of the weaker power, changed fundamentally. Increase of diving depth and submerged speed, improved submarine weapons, and more efficient means of communication indicated that the influence of the submarine on naval warfare was still growing. The vulnerability of seaborne trade to submarine attack having been convincingly demonstrated in both world wars, it was natural that mercantile nations, including Britain, should pay close attention to antisubmarine defense. Sonar (the use of sound waves underwater on the radar principle) was greatly improved and made to record a submarine's depth as well as its range and bearing. (See *SOUND: Applications: Military: Underwater Detection*.) Automation was applied extensively to antisubmarine weapon control. Helicopters fitted with dunking (dipping) sonar and operated from surface ships greatly extended the range of detection; and antisubmarine guided homing torpedoes were developed to seek out their targets in the depths. Such developments undoubtedly reduced the lethality of the conventional submarine, despite its greatly improved performance. But the U.S. Navy's adoption of nuclear energy for propulsion in 1955 revolutionized all earlier submarine concepts, because the range and duration of operations were thereby rendered virtually unlimited; and the nuclear submarine at once became the most efficient and economical carrier for launching intercontinental missiles. Thus did the submarine become a major factor in deterrent strategy as well as conventional maritime strategy.

In the search for measures to restrict the dominance of submarines the U.S. and Britain both devoted considerable effort to developing hunter-killer nuclear submarines. These vessels, with improved means of detection and communication, and with new antisubmarine weapons such as rocket-propelled homing torpedoes, were expected to narrow the gap between defense and offense. Nevertheless, the submarine had firmly established itself as the capital ship of the nuclear era. Moreover, the scope for the employment of submarines on duties hitherto performed by surface ships or aircraft appeared to be limited only by the cost of submarine production. Indeed, the command of the surface sea, whereby a maritime power seeks to secure the uninterrupted passage of mercantile or military cargoes, seemed likely to depend increasingly on control of the waters beneath. (S. W. R.)

**SUBMEDIANT**: see SCALE.

**SUBOTICA**, a town of Vojvodina Province, in the Socialist Republic of Serbia, Yugos., lies on the Belgrade–Budapest railway line about 100 mi. (160 km.) NNW of Belgrade. Pop. (1961) 75,036. It is the centre of the Bačka, a fertile agricultural district, and is also an important industrial town. Its chief manufactures are iron products, rolling stock, chemicals, and furniture. The Faculty of Economics of the University of Novi Sad is at Subotica.

The town was first mentioned in 1391. After the defeat of the Turks at the end of 17th century, it was included in the Military Frontier. In later years many Serbs emigrated from Subotica to Russia, and large numbers of Hungarian settlers then moved in. Subotica joined Yugoslavia in 1918. During World War II it was occupied by Hungarian troops, and after 1945 it was restored to Yugoslavia. (V. DE.)

**SUBSIDY**, the promotion of private business enterprise by direct or indirect government action, frequently involving the granting of special privileges. Government subsidies to shipping, aviation, mining, agriculture, and other industries are granted in many countries throughout the world. See *AGRICULTURAL ECONOMICS: Agricultural Prices and Incomes*; *AVIATION, CIVIL*; *SHIPPING: International Problems*; *SHIPBUILDING: Subsidies*.

Though some subsidies may be criticized as obvious favours to special interest groups at the expense of the economy as a whole, others may serve to encourage activities that are generally regarded as socially desirable. Subsidies to aid the settlement of new lands, to support bona fide infant industries, to provide government statistical services, and to carry on basic scientific research (with results made available to all) are rarely questioned. On the other hand, paying above-market prices for certain metals, subsidizing irrigation when excess acreage already exists, making payments to a select group of growers of agricultural products, and giving favoured tax treatment to certain industries may be of dubious merit.

It is necessary to distinguish direct or visible subsidies, such as airmail subsidy grants, direct payments for ship construction, and payments to cover operating deficits, from indirect or concealed subsidies, which are more widespread but are often not recognized as subsidies. The latter include tariffs, quotas, and other trade restrictions that exclude foreign competitors; the provision of government services for which no charge is made; the sale of goods and services for which no, or an insufficient, charge is made; the purchase of goods and services for more than they are worth; government loans at lower than the market rate of interest; and the exemption of some enterprises from various forms of taxes that others in a similar position must pay.

It is obvious, of course, that the very existence of a government, which includes a legal system, a monetary system, and the establishment of standards and grades of quality, facilitates the conduct of business. A subsidy goes beyond such activities, however; its purpose usually is to maintain or improve the position of certain businesses or private interest groups, without commensurate public gains. In this sense, subsidies are an outgrowth of the protectionism of the mercantile system (*q.v.*), under which governments used special forms of regulation or restraint, particularly import duties, quotas, and fiscal expedients, in order to

maintain, encourage, and promote "essential" industries that were endangered by foreign competition. Tariffs, import quotas, and other trade restrictions serve to exclude competitors from the home market or limit their access to it, thus enabling protected sellers to charge higher prices. The result is a transfer of income (or subsidy) from consumers of the protected goods to the favoured domestic producer.

In the case of industries that do not need protection to remain in business, tariffs and other restrictive devices merely enhance profits. Industry protection through trade restrictions causes a shift in the nation's resources from more productive to less productive uses. The objective underlying a policy of protection, aside from questions of national security and power, is to provide a balance of economic activities and power among various economic groups, both nationally and internationally. Use of such a doctrine to protect infant industries of a country until they expand sufficiently to attain an efficient level of operation often is extended to justify a variety of protectionist measures, without demonstrable public gains to either the domestic or international community. Once protectionist measures are justified on the ground that they benefit infant industries, they are often extended to cover lost markets (both real and imagined), as well as new markets. Thus, protectionist devices and subsidies are in reality practical expedients, not unlike other forms of controls designed to deal with specific problems or to accommodate special interest groups.

Nations have retreated in varying degrees from mercantilist protective measures toward freer trade, but other methods of protection, support, and promotion of private industry have become important in the functioning of economic systems of today. In the United States, where businessmen lay great stress on preserving the free-enterprise system, subsidy has become so pervasive as a means of effectuating public policy that it can properly be said the economy has entered an age of government by subsidy. In the 1960s, for example, up to \$15,000,000,000 per year, or roughly 15% to 20% of the total U.S. budget, was allocated for benefits to interest groups, such as farmers, small and big businesses, veterans, and others, not including hidden subsidies covered under such items as interest, national security, federal highway program, and international affairs.

**Direct Subsidies.**—Railroads, transoceanic shipping companies, shipbuilders, and airlines have been given various forms of subsidy by almost all developed countries at one time or another. Direct gifts of land and construction funds were given to the railroads in connection with the settlement and development of the United States. In more recent years, railroad subsidies have consisted of authorization for railroads to amortize new investment more rapidly than usual, thus reducing their tax liability, and government guarantee of repayment of private loans to the railroads for the purchase of new equipment.

The most important subsidies in this field are for ship construction, payments for operation of transoceanic merchant vessels, establishment of cargo preferences for domestic lines, and exemption of profits from corporate income taxes under certain conditions. The U.S. government ship construction subsidy amounts to the differential between cost of construction in U.S. and in foreign shipyards, not to exceed one-half the cost (except where defense features are included). The liner "United States," for example, cost approximately \$77,000,000, of which taxpayers provided \$44,000,000. The subsidy to operators of transoceanic vessels, hidden for many years in excessive payments for carrying the U.S. mail, was brought out in the open during the 1930s as an "operating differential" between the cost assumed to be involved in operating under the U.S. flag rather than under a foreign flag.

Operating subsidies, or airmail subsidies, are fairly common as a means of promoting airlines. As early as 1924, for example, the British government provided a subsidy for Imperial Airways, Ltd., to develop air routes to the Commonwealth countries. During the 1950s the United States paid commercial airlines \$500,000,000 in such subsidies.

Agriculture has received various direct subsidies, including gifts

of land, export subsidies, and provision of a variety of services, such as market information, agricultural research and education and protection from crop pests and animal diseases. Federal support for agricultural education and research alone have averaged several hundred million dollars per year in the United States.

**Indirect Subsidies.**—Indirect subsidies are the most widespread form of assistance to private enterprise, particularly in the United States. One type, the payment in excess of actual cost or market value, includes the purchase of silver for monetary purposes, the purchase of certain metals for stockpiling, and the purchase of agricultural commodities. Under domestic producer preference laws, government procurement officers must purchase goods made at home unless their price exceeds the price of goods made abroad by more than a specific percentage. The U.S. mining industry benefits from a federal law requiring the government to buy supplies at above market prices and in excess of its needs. For many years the entire domestic output of silver has been sold to the U.S. government at prices in excess of the international price; meanwhile the silver used by industry for commercial purposes was purchased from foreign sources at lower prices. Federal, state, and local governments all have provided subsidies to shipping by dredging rivers and building canals. Aviation has benefited from the construction of airports, provision of airways, traffic control equipment, weather-reporting facilities, radio beams, and instrument landing systems.

One of the most important subsidies in the United States is the price support program for 12 basic crops, with special emphasis on wheat, corn, and cotton. The subsidy operates through government "nonrecourse" loans: if market prices go above an arbitrary support level (minimum price), the farmer can pay off the loan and repossess his crop pledged as collateral. If prices fall below the support level, the farmer defaults on his loan, keeps the money loaned him, and the government takes the loss. These subsidies amounted to about \$1,000,000,000 per year in the 1960s, with principal benefits accruing to the large, corporate-sized farms.

Indirect subsidies to farm operators also arise in connection with the building of farm-to-market roads, which in part are paid for with city gasoline tax revenues and federal support.

Other indirect subsidies consist of free or partially required services, ostensibly available to all persons and businesses but actually of benefit to only a few enterprises. The trucking industry, for example, is subsidized indirectly to the extent that taxes imposed on trucks to cover the cost of highway construction and maintenance do not equal the benefits received. In addition, the tax burden falls heaviest on light, gasoline-powered vehicles (including passenger cars) as against heavy, diesel-powered vehicles.

Owners of irrigated farmlands are heavily subsidized; settlers are given long-term, low-interest loans that work out so that they pay only about one-half of the real cost to the government; in multipurpose water projects, the direct beneficiaries of federal irrigation pay only a minor part of their cost, the remainder being paid by taxpayers and other water users. Power companies receive subsidies in connection with the generation of electricity from atomic fuels; i.e., in government-supported research, the price charged for the nuclear material, and the price paid by the government for nuclear wastes and residues.

Two other important types of indirect subsidies arise out of government guarantees and various kinds of special tax reduction to private industry. In the first, the government assumes a contingent liability on private investments, debts, and contracts, without requiring an equivalent public benefit, such as an equivalent reduction in price. Included here are guarantees on investments abroad, on loans to feeder or local-service airlines, on mortgage lenders' loans to home buyers, and on loans to small businesses, farmers, and railroads. Tax reduction as a subsidy includes the exemption of new businesses from local property taxes and of income from certain securities, accelerated amortization of plants (which as a minimum provides an interest-free loan), and the special "depletion" allowance for the mining industry. In the case of mining, not only are the costs of exploration and develop-

ment deductible as current costs for tax purposes but mining companies also have the option of making an arbitrary deduction for the "depletion" of assets (in the United States at rates of from 5% of gross income for coal, sand, and gravel up to 27½% for oil and gas), instead of deducting the actual depletion through the estimated life of the assets. In the United States the depletion allowance is limited to a maximum of 50% of net income, but this can reduce corporate tax liability from 52% down to 26%.

Other indirect subsidies include the sale of war plants and merchant vessels to private industry at a fraction of their original costs and disposal of surplus commodities at less than buying prices plus storage and interest costs.

**SUBSTANCE.** In traditional philosophy a substance is a thing that exists independently and persists through change; but the notion has been developed in different ways by different philosophers, and it is impossible to judge of its value without a summary of its history.

**Origins of the Term.**—The Greek word sometimes translated as "substance" is *ousia*. Its earliest and most widespread use in Greek literature is for property or estate, but it is similar in origin to "being" and it was in fact used by Plato and Aristotle in a non-technical way to signify being in the sense of "essence," being in the sense of "existence," and being as opposed to becoming. The beginning of the technical usage now rendered by "substance" is to be found in Aristotle's *Categories*, 5:

"Substance (*ousia*) in the . . . primary . . . sense of the word is that which is neither predicable of a subject nor present in a subject. . . . But in a secondary sense those things are called substances within which, as species, the primary substances are included. . . . Thus everything except primary substances is either predicated of primary substances or is present in them. . . . The fact that parts of substances appear to be present in the whole, as in a subject, should not make us apprehensive lest we have to admit that such parts are not substances: for in explaining the phrase 'present in a subject,' we stated that we meant 'otherwise than as parts in a whole.' . . . The most distinctive mark of substance appears to be that, while remaining numerically one and the same, it is capable of admitting contrary qualities. . . . The same individual . . . is at one time warm, at another cold. . . . This capacity is found nowhere else."

Use of "being" as a translation for *ousia* in this passage might perhaps give a clearer impression of Aristotle's intention. For he does not wish to fix the sense of a term that would otherwise be unintelligible. On the contrary, assuming that his reader knows the meaning of *ousia*, he asserts the existence of certain *protai ousiai* ("prime beings," e.g., Socrates), presupposed by all talk of other things. Similarly, in his *Metaphysics* he announces that *ousia* is the principal subject of his study, as though everyone knew what he meant by that term, and then sets out to determine where it may be found. His conclusion in this work is similar to that in the *Categories*, but in his argument he attacks the doctrines of other philosophers (e.g., Ionian theories about a primal stuff and Plato's assertion that "forms" exist independently), and he also makes a rather bewildering shift in his use of *ousia*. If we here translate the Greek by "substance," we must allow for a distinction between a substance (i.e., an individual thing) and the substance of a thing (i.e., what is fundamental in its being). According to *Metaphysics*, vii, the substance of a thing is what makes it what it is, and this is its form or essence (i.e., the defining character of the species which in the *Categories* he described as a substance in a secondary sense). In addition to their form all ordi-

nary substances have matter, and it is this which distinguishes them as individuals, though matter cannot exist without form. There are, however, some substances (God and the Intelligences in control of the planetary spheres) which have no matter; Aristotle does not explain how they are individuated.

The Latin word *substantia* appears first in the younger Seneca's *Epistulae*, 58, with the sense of "reality"; and slightly later occurrences show that at the end of the 1st century A.D. it had the whole range of uses of the Greek *ousia*. This exact correspondence is curious, since the etymology of *substantia* (literally "standing under" or "near") is different from that of *ousia*, but the circumstances in which *substantia* occurs suggest that it was not a deliberate neologism introduced for the purpose of translating the Greek. In later Latin *substantia* retains its wide range of usages: thus *consubstantialis* occurs in the Latin version of the Nicene Creed as a translation for the Greek *homoousios*, meaning "of the same essence." In English "substance" has acquired yet other meanings (e.g., "kind of stuff"), but is now generally reserved by philosophers for Aristotle's "prime being," while other terms such as "essence" and "existence" are used for the other senses of *ousia*.

**Medieval and Modern Theories.**—Medieval Aristotelians, such as St. Albertus Magnus and St. Thomas Aquinas, retained the master's doctrine of substance for the most part unchanged; but they felt difficulties about individuation that had not distressed him. According to St. Thomas, angels are without matter (as Aristotle said of his Intelligences) and must therefore be distinguished one from another in respect of their forms; i.e., must each be of a different species (*Summa theologiae*, I, x, 6). The problem presented by human souls is even more serious. According to Aristotle's *De anima*, which St. Thomas followed, a soul is the form of the living body that it animates. This view may perhaps be reconciled with Christian doctrine, but what of the interval between death and the resurrection of the body? During that time, it seems, souls must continue to exist as separated forms, though this condition is unnatural for them (*Summa theologiae*, I, lxxvi). These were among the difficulties that produced a reaction against Aristotelianism during the Renaissance; but to the founders of modern physics the most irritating feature of the system was that it deluded men into thinking that they had given an explanation of a fact when they had merely formulated it in a technical jargon. The statement that a substance originated through the reception of a form in matter might perhaps be defensible by an array of definitions, but it was useless for science.

This is not to say, however, that physicists of the 17th century had no use for the concept of a thing that existed independently of all else and persisted through change. On the contrary, many of them adopted the atomic theory suggested in antiquity by Democritus, and their reasons were a priori, like those of its ancient champions; for it was not until the time of John Dalton (1766–1844) that the atomic hypothesis was used in a scientific fashion to explain empirical generalizations. Since ordinary observable things come into being by the aggregation of parts and are destroyed by the separation of parts, it is plausible to suppose that there are very small things which never come into being or pass away but constitute all observable things by entering into close spatial relations with each other. This conclusion seems, indeed, to be required by the principle that nothing is made of nothing or resolved into nothing (Lucretius, *De rerum natura*, i, 147 ff.). Aristotle did not accept the atomic theory of his day and did not define substances as things that are everlasting; but there is a connection of thought between the atomist's belief in simple bodies and his doctrine of ultimate subjects. In a surviving fragment of his work *On Democritus*, he himself speaks of atoms as little substances, and it is not surprising that some philosophers of the 17th century came to think of atoms as the only genuine substances.

The new orthodoxy established at the end of the 17th century by Newton and Locke allowed for two kinds of basic things, atoms and souls; but there were some curious developments among philosophers who tried to take seriously the notion of a substance as something which requires nothing else for its own existence. Descartes (who gave this definition in his *Principia philosophiae*,

i, 51) agreed with the demand for mechanical explanation of natural phenomena, but rejected atomism as self-contradictory (*ibid.*, ii, 20). According to his philosophy there is only one *res extensa*, though there are many *res cogitantes*, or minds. Spinoza went farther and argued that there could be only one substance, Nature or God, which comprised in its infinity the attributes both of extension and of thought. Whereas Descartes had allowed the title of substance by courtesy to things which were independent of all else except God, Spinoza denied the existence of created substances (*Ethica*). Frightened by this pantheism, Leibniz reverted to the view that there were many substances, but maintained that nothing extended could be a substance, since its existence presupposed the existence of its parts. According to his view, all substances must be conceived by analogy with minds, because these alone have the simplicity necessary for independence; and it must further be supposed that each has its experiences without being affected by any other, because causal interaction would be inconsistent with independence (*Discours de métaphysique; Monadologie*).

These surprising results were all derived from attempts to take the notion of independent existence in a much stricter way than Aristotle ever contemplated. So too the criticism which the doctrine of substance received a little later from Locke, Berkeley and Hume was based on a concept foreign to Aristotle. These philosophers all maintained that ideas must be derived from experience; but Locke held also that the ideas obtained in sense-perception were representative of the qualities of physical things and found himself driven to admit that he had no idea of a substance except that of a something-he-knew-not-what serving as support to qualities (*Essay Concerning Human Understanding*, I, iv, 18). It is not surprising that Berkeley declared talk of material substance to be meaningless, or that Hume went on to declare talk of a spiritual substance equally meaningless. Throughout the argument it was assumed that "substance" meant something standing under qualities. But Aristotle never taught that a substance was a featureless substratum of qualities; and apart from that, it is surely a mistake to speak of qualities as though they were drapings. (See QUALITIES.)

Hume, who held every impression or idea to be a distinct existence, says in one place that if anything may be called a substance which may exist by itself, then his perceptions are substances (*Treatise of Human Nature*, I, iv, 5). The remark is interesting because it had always been assumed without question that anything which satisfied Aristotle's first requirement must also persist through change. When he tried to rehabilitate the doctrine of substance after the attacks of the empiricists, Kant made this a matter of definition (*Critique of Pure Reason*, "First Analogy" of Experience). But it is difficult to be certain about the interpretation of Kant's doctrine; for he tried to justify it by saying that it was presupposed in our perception of change, suggesting also that it was the same as the principle of the conservation of matter. Clearly the continuants (to adopt a term from W. E. Johnson's *Logic*) which undergo perceived changes are themselves perceived, whereas the particles which scientists have supposed to be conserved through all change are not perceived.

In the 20th century Bertrand Russell ("The Philosophy of Logical Atomism," in *The Monist*, 1918-19) and A. N. Whitehead (*An Enquiry Concerning the Principles of Natural Knowledge*, 1919) made once more the distinction that Hume had indicated between Aristotle's two notions. According to their arguments, there must be simple and ultimate particulars which are the subjects of basic facts: Russell called them logical atoms. These satisfy Aristotle's first requirement for a substance, though it may be undesirable to call them by that name, since it suggests permanence, or at least persistence for a long time, whereas they are minimal events. To say that such events happen to a continuant can only mean that they form a temporal series in which each has a close resemblance to its neighbours and is causally connected with them.

**The Value of the Notion.**—There are undoubtedly substances such as Aristotle describes in his *Categories*. For according to his explanations a substance is just a thing, not in the sense in which things are contrasted with persons, but in the larger sense in which

things are contrasted with attributes, such as manhood, with abstractions, such as grammar, and with the events that occur to them. It is not quite correct to say, as Aristotle does, that these things are the only subjects of change (for even Greek grammar has changed since his day); but they can undoubtedly change in respect of inessential characters. Are there also substances corresponding to the narrower definitions of later philosophers? In order to answer this question we must distinguish between the requirement of independence and that of permanence.

If we insist that nothing with parts shall be called a substance, we must agree with Leibniz that there can be no extended substances. This consideration is fatal to the a priori atomism of Democritus and also to that of Whitehead and of Russell. For in each case that which is offered as a substance is complex in the same way as entities disqualified for the title. There may, of course, be good scientific reasons for believing in physically indivisible particles or in events that are, so to say, natural units; but an a priori argument for atomism of either kind is fallacious in the same way as an argument from the principle of universal causation to the necessity of a first cause. It would be an equally serious mistake, however, to suppose that the extended world is composed of unextended substances. For although anything punctiform or instantaneous is not dependent for its existence on other things in the way in which a whole is dependent on its parts, it is dependent in another way, namely, in the way in which a boundary is dependent on that of which it is a boundary. There is, indeed, no absurdity in the suggestion that everything is dependent on something else in some way. Why should we suppose that some thing or things must be independent of everything in every way?

On the other hand, the search for something permanent through all change has been of the greatest importance in the development of science. For it has led not only to the primitive atomic theory of Democritus, but also to the principle of the conservation of energy (*q.v.*). Unlike the Democritean theory, the latter principle was formulated in connection with experimental inquiries, but it is a postulate that guides research rather than a generalization that might be refuted by a counterexample. Nature is intelligible only insofar as it is conservative, but it is not necessary for its intelligibility that what it conserves should be stuff.

**SUBUKTIGIN** (c. 942-997), ruler of Ghazni (in modern Afghanistan) from 977 to 997 and father of the great conqueror Mahmud. Born in Barskhan, on the shores of the Issik-Gol (Issyk-Kul'), of a Qarluq father, Subuktigin was captured by a neighbouring Turkish tribe and sold to a slave dealer who eventually took him to Bukhara. About 959 he was purchased by Alptigin, a Turkish military officer of the Samanid kingdom, and when in 962 Alptigin established himself as a semi-independent ruler at Ghazni he took Subuktigin with him. Marrying a local chief's daughter and becoming popular under Alptigin's successors at Ghazni, Subuktigin in 977 was accepted as ruler of Ghazni by the local Turkish soldiery. He did not, however, claim formal independence from the Samanids. His rule was notable for the extension of Ghazni's power in the direction of both Hindustan and Khurasan. His defeats of Raja Jaipal, of the Hindushahiyya dynasty, in 986 and 987 led to the Hindushahiyyas' loss of control of the Kabul Valley.

In 994, as a reward for serving his Samanid overlord, Amir Nuh II, against rebels, Subuktigin acquired the governorship of Balkh. In 996 he so far forced his will upon Nuh as to conclude a peace for him with the Qara-khanid Turks of the steppe, a peace defining the mutual limits of their territories. At his death near Balkh in August 997, Subuktigin was in control of the Samanid provinces south of the Oxus (Amu-Darya), bequeathing a power that his son Mahmud (*q.v.*) of Ghazni was to make imperial. See also GHAZNI; SAMANIDS.

**SUBWAY (UNDERGROUND RAILWAY)**, an underground electric railway system used to transport large numbers of passengers within urban and suburban areas. Subways are usually built under city streets although they may cross under rivers and take shortcuts. Outlying sections usually emerge into the open, becoming elevated or conventional electric railways. Subway trains are usually made up of a number of cars operated on the multiple-unit system, as distinct from the single car or car and trailer of street railways (tramways).

**History.**—The world's first subway system was proposed for London by Charles Pearson, the city solicitor, as part of a city improvement plan shortly after the opening of the Thames Tunnel in 1843. After years of discussion, Parliament in 1853 and 1854 authorized the construction of 3.75-mi. (6.03-km.) underground railway between Farringdon Street and Bishop's Road, Paddington. Work on the Metropolitan District Railway began in 1860 by cut-and-cover methods, that is, by making great trenches along the streets, giving them brick sides, providing girders or a brick arch for the roof, and then restoring the roadway on top. This brick tunnel was 17 ft. (5.18 m.) high and, in order to take two tracks of the broad 7-ft. (2.13 m.) gauge, 28.5 ft. (8.68 m.) wide. The line was opened on Jan. 10, 1863, using steam locomotives that burned coke (later coal), and, in spite of the sulfurous fumes, the line was a success from the start, carrying 9,500,000 passengers in the first year of its existence.

In 1886 the City and Southwark Subway Co. (later the City and South London Railway) began work on their "tube" line, using a tunneling shield developed by J. H. Greathead (*q.v.*). This was an improvement over both the rectangular shield used by Sir Marc Isambard Brunel for the Thames Tunnel and the round shield of Greathead and Peter W. Barlow used on the Tower Subway of 1870. (This was a 7-ft.-diameter cross-river tube with a cable-hauled car, soon converted to a pedestrian subway.) The Greathead shield of 1886 used hydraulic jacks with a thrust of 200 tons to force its way through the ground by pushing against the cast-iron segments of the completed tunnel. It provided protection for the men excavating and lining the 10-ft. (3.05-m.) diameter single-track tunnels. Penetrating the London clay was fairly straightforward, but in wetter formations, such as gravels, compressed air was used. The tunnels were driven at such a depth as to avoid interference with building foundations or public utility works, and there was no disruption of street traffic. The original plan was for cable operation, but electric traction was substituted before the line was opened. Operation began on this first electric underground railway in 1890 with a uniform fare of twopence for any journey on the three-mile line. (See also TUNNEL.)

Charles Tyson Yerkes, a U.S. railway magnate, arrived in London in 1900 and was responsible for the construction of more tube railways and for the electrification of the cut-and-cover lines. Albert Stanley (later Baron Ashfield), at one time general manager of the Public Service Corporation of New Jersey, went to London to manage the Yerkes subways in 1907 and succeeded in establishing a single controlling authority when, in 1933, virtually all the London underground system was absorbed by the London Passenger Transport Board.

**The London Transport System.**—By the 1960s London Transport trains were serving 273 stations spread over 244 route miles (393 km.), of which 88 mi. (141 km.) were underground (66 mi., 106 km., in deep, twin-tube tunnels and 22 mi., 35 km., in cut-and-cover subsurface double-track tunnels). In 1965 the

new Victoria Line, with 10.5 mi. of tube tunnels, was under construction. The standard tube tunnel is 11 ft. 8.25 in. or 12 ft. (3.66 m.) in diameter and lined with cast-iron segments except for a short section of the Central Line where reinforced concrete was used. The track gauge is the standard 4 ft. 8.5 in. (1.43 m.), although the original section of the Metropolitan Line retained its broad-gauge tunnel. Electric power at 600 v. DC for the multiple-unit trains comes mainly from London Transport's own generating stations. Automatic track-circuit signaling with coloured lights and train stops permits a theoretical maximum of 40 trains an hour each way, but with station stops the maximum peak-hour service is 32 to 35, carrying about 40,000 passengers per hour. The average speed, with stops, is 20.5 mph (33 kph), roughly double that of surface transport in peak hours. Speed-control signaling is employed on central area tracks with heavy traffic. The rolling stock is of two sizes: the tube cars have to fit the 11-ft. 8.25-in. tunnels, but the subsurface cars are virtually of main-line cross section. Where tube and subsurface or main-line railways connect, safety devices guard against the larger cars' being driven toward a tube tunnel. Maximum length of trains is eight cars to carry 328 (tube) or 460 (subsurface) seated passengers plus about 1,000 standing. In the 1960s the system carried each year about 673,000,000 passengers on an average journey of 5 mi. Because of the depth of the tubes, hydraulic and electric elevators (lifts) were provided at the stations, but since 1911 many of them have been replaced by escalators. In World Wars I and II tube stations performed an unintended function as air-raid shelters.

**Other British Systems.**—In 1886 the 4.75-mi. Mersey Railway was opened from an underground terminus under Liverpool Central Station through a double-track tunnel under the River Mersey to Birkenhead. In 1903 it became the first steam underground railway to be converted to electric traction. Since 1938 trains from the electrified Wirral suburban line have been projected over the Mersey Railway.

In 1886 2.75 mi. of a steam suburban line penetrated central Glasgow in a double-track tunnel. In 1891 work was begun on a 6.5-mi. subway loop, using both shield and cut-and-cover methods of construction. In 1894 there was a disastrous series of blowouts under the River Clyde, and work was temporarily abandoned, but the 410-ft. section under the river was later completed. The 4-ft. gauge trains were cable operated until 1935, when the line was electrified on a 570-v. DC third-rail system.

**Other European Systems.**—A 2.5-mi. electric subway in Budapest opened in 1896, using single cars with trolley poles; it was the first subway on the European continent. By using a flat roof with steel beams instead of a brick arch and, therefore, a shallower trench, considerable savings were achieved over earlier cut-and-cover methods.

The Paris system, called the Métro (*Chemin de Fer Métropolitain*), was started in 1898, and the first 6.25 mi. were opened in 1900. Rapid progress was attributed to the wide streets overhead and the modification of the cut-and-cover method devised by the engineer Fulgence Bienvenüe. Vertical shafts were sunk at inter-

(LEFT) LONDON TRANSPORT BOARD; (RIGHT) NOVOSTI PRESS AGENCY

(LEFT) BAKER STREET STATION PLATFORM, LONDON, IN 1863; (RIGHT) MARBLE HALL AT KOMSOMOLSKAYA STATION, CIRCLE LINE, MOSCOW

vals along the route, and from there side trenches were dug, with masonry foundations to support wooden shuttering immediately under the road surfaces. Construction of the roof arch then proceeded with little disturbance to street traffic. This method is still used in Paris but has not been copied to any great extent.

In the 1960s the Métro consisted of 14 lines with about 270 stations. In addition, the Sceaux Line had 28 stations, so that the system gave excellent coverage of Paris and its suburbs. With about 120 route miles, it was the third largest system in the world, and in number of passengers carried—more than 1,100,000,000 a year—it was second only to that of New York City.

A development on some lines in Paris has been the introduction of pneumatic-tired trains running on wood or concrete strips, with ordinary wheels and rails retained for emergencies and for running through switches. This system provides quieter running, faster acceleration, and improved speeds, while reduced vibration permits lighter construction.

Berlin's subway system, the U-bahn, opened in 1902, and by the 1960s there were in West and East Berlin 55.5 route miles, with 111 stations. The ten lines carried about 240,000,000 passengers each year. The Hamburg subway had 64 stations, 45.25 route miles, and 167,100,000 passengers a year.

Continental Europe's second largest system is the Moscow Metro, distinguished by its lavishly decorated and spacious stations. No two are alike, and they are finished in polished marble and granite, with decorations in mosaic and coloured glass and embellished with statuary. Work began in 1932, and the first line opened in 1935. Most lines are of tube construction, with twin tunnels 17 ft. in diameter and containing single 5-ft. gauge tracks. The Moscow subsoil proved far more difficult to penetrate than the London clay, but this did not prevent the extension of the system. By the 1960s there were 87 route miles with 82 stations carrying more than 1,000,000,000 passengers a year. Other European subways operate in Stockholm, Vienna, Madrid, Athens, Leningrad, Lisbon, Rome, Milan, Barcelona, Kiev, and Oslo. In the 1960s subway construction was proceeding in, among other places, Budapest and Rotterdam. Few of the European systems are entirely in tunnels; in some cases tracks run on the surface in outer districts, as in London, or there are urban elevated sections, as in Paris and Hamburg. Most of the lines have standard-gauge tracks, except those of the U.S.S.R. with a 5-ft. gauge and Spain with a 5-ft. 6-in. gauge. Nearly all have automatic signaling with coloured lights. In Stockholm all trains have cab-signaling indicating the correct speed for the section; if ignored, the brakes are applied automatically.

**North American and Other Systems.**—The first practical subway line in the United States was constructed on the cut-and-cover principle in Boston between 1895 and 1897. It was 1.5 mi. long and used trolley streetcars (tramcars). Later, Boston acquired conventional subway lines.

New York City tried to solve its transportation problem by constructing elevated railways, mainly because of the resistance of its subsoil to tunneling. However, in 1900 a subway program was started, and work progressed rapidly. The first experimental line, only 296 ft. (90.22 m.) in length, had been built in 1870 beneath Lower Broadway by Alfred E. Beach, editor of the *Scientific American*. Cars were propelled in a tube by compressed air, using the cars as a plunger and the tube as a cylinder. Financially the line was unsuccessful, and it closed after a few years. The first conventional line in New York City was built from City Hall to Dyckman Street for the Rapid Transit Commission, with William Barclay Parsons as chief engineer and John B. McDonald as contractor. The first section was opened on Oct. 27, 1904. Almost all subway construction in New York City was paid for by the city authorities and then turned over to two private companies, the Interborough Rapid Transit Company (IRT) and the Brooklyn-Manhattan Transit Corporation (BMT). However, in 1925 construction of a third subway was begun, the Independent city-owned subway (IND), to be operated by the city. The first IND line was opened in 1932–33 from Washington Heights, going south under Eighth Avenue. Unification of all lines under public auspices took place in 1940, and the system is now owned by the

WIDE WORLD

AIR-CONDITIONED TRAIN, PART OF THE LARGEST SUBWAY SYSTEM IN THE WORLD, STOPS AT THE 33RD STREET STATION IN NEW YORK CITY

city and operated by the New York City Transit Authority, under the control of the state of New York. However, the Hudson Tubes, linking Manhattan and New Jersey, are run by the Port of New York Authority. New York City has the largest system in the world, consisting of 245.3 route miles with 495 stations carrying about 1,400,000,000 passengers a year.

Other subways in the United States are in Philadelphia, opened in 1907, and in Chicago, opened in 1943. Toronto, in Canada, opened a subway in 1954, and further construction was proceeding in the 1960s. For the second Canadian system, under construction in Montreal in the 1960s, Paris-type rubber-tired cars were to be used. In South America the Buenos Aires subway opened in 1913. Japan had lines in Tokyo (1927), Kyoto (1931), Osaka (1933), and Nagoya (1957).

**New Construction.**—The end of World War II heralded an impressive spate of construction, with new lines in Leningrad, Kiev, Milan, Lisbon, Toronto, Stockholm, Nagoya, Rome, Haifa, and Istanbul. Later construction was planned for Rotterdam, Warsaw, Oslo, Budapest, and Montreal. Existing systems, such as those in London, Moscow, and Berlin, built new extensions, while London, New York, and others modernized their lines and built new rolling stock. By the mid-1960s, 27 cities without subways were either considering them or had reached the stage of detailed planning. All this activity could be related to the increased needs of commuters, placing an increasing strain on surface transportation. Even in cases where subways might not be commercially successful in themselves, they could be justified by their contribution to the total economy.

**Construction Problems.**—The main problem of subway construction has always been the consideration of existing property. Utilities, including sewers, gas and water mains, telephone and power lines, steam mains, and mail tubes, must be avoided or else diverted. Apart from the early cut-and-cover lines in London, provision has usually been made for maintaining road traffic during construction. Interference with the foundations of buildings was a problem with the early subsurface and tube lines in London, but later lines were constructed sufficiently deep in the subsoil to avoid this problem. In Paris the wide boulevards helped the engineers avoid buildings. New York City has a high proportion of tall buildings, which, because of their weight, present special problems. Normal New York practice has been to retain the side walls of the trench with steel beams and horizontal wood lagging with a temporary deck to carry traffic above it. However, some buildings that needed underpinning during subway construction led to development of the pretest pile by Lazarus White and Edmund A. Prentis. These piles are installed by jacking steel cylinders under a building to support it at a level below the subgrade of the subway. The piles are preloaded for the weight of the building and wedged up to prevent the elastic rebound of the earth. Many buildings that have been underpinned in this way now rest on the roof of the subway.

**Traffic Control.**—The signal system is a vital part of subway operation. Its purpose is twofold: to ensure safety with speed, especially by preventing conflicting movements, and to secure proper spacing of trains to maintain schedules and achieve maximum track usage. Train movements are controlled by coloured lights placed either at the side of the track or in the motorman's cab. The lights are operated automatically through track circuits each circuit covering a short section of track and indicating its status to any approaching train. Interlocking devices at junctions prevent signalmen from setting up conflicting movements. Perhaps as a preliminary step to automatic trains, London Transport made considerable use of automatic traffic control. This was achieved by means of prepunched plastic "program rolls" carrying the day's train service, which passed through a machine operating signals and switches (points) by relays.

**BIBLIOGRAPHY.**—E. A. Course, *London Railways* (1962); T. C. Barker and M. Robbins, *A History of London Transport*, vol. i (1963); J. R. Day, *Railways Under the Ground* (1964); H. F. Howson, *World's Underground Railways* (1964). (E. A. Co.)

**SUCCINIC ACID** is an organic compound occurring in amber (3% to 8%), from which fossilized gum it is obtained by distillation. It is also found in other resins, in lignites, in fossilized woods and in many plants.

It is present at low concentration in a great variety of animal tissues, where it has an important function in intermediary metabolism (see **KREBS CYCLE**).

Chemically, succinic acid, or butanedioic acid,  $\text{CO}_2\text{HCH}_2\text{CH}_2\text{CO}_2\text{H}$ , is a saturated dibasic acid which crystallizes in colourless prisms or plates melting at  $186^\circ\text{C}$ . and boils at  $235^\circ\text{C}$ . Its vapour readily loses water to form succinic anhydride (formula I), which crystallizes in plates melting at  $120^\circ\text{C}$ .

The acid itself is soluble in water, and its salts with the alkali and alkaline-earth metals are also soluble in water. Barium succinate is precipitated from aqueous solution by alcohol; ferric succinate is insoluble in water and is sometimes employed in the analytical separation of iron from other metals.

When heated with phosphorus trisulfide, sodium succinate yields thiophene.

Succinic acid is produced during the bacterial fermentation of ammonium tartrate or calcium malate. It may be prepared synthetically from ethylene,  $\text{C}_2\text{H}_4$ , through ethylene dichloride,  $\text{C}_2\text{H}_4\text{Cl}_2$ , ethylene dicyanide or succinonitrile,  $\text{C}_2\text{H}_4(\text{CN})_2$ . The last compound yields the acid on hydrolysis.

Maleic acid, produced industrially by catalytic oxidation of benzene, yields succinic acid on reduction with sodium amalgam.

Succinyl chloride (formula II) is obtained by the interaction of phosphorus pentachloride and succinic acid. Succinic anhydride (formula I), also produced by heating the acid or its salts with acetic anhydride or by heating succinyl chloride with anhydrous oxalic acid, is employed as an intermediate in dye making. It is employed also in the manufacture of alkyd resins (see **RESINS**) and is an important reagent in organic chemical synthesis.

Succinimide (formula III), produced by heating succinic anhydride in ammonia, crystallizes in colourless octahedra melting at  $125^\circ\text{--}126^\circ\text{C}$ . and readily soluble in water. This imide when distilled with zinc dust furnishes pyrrole (*q.v.*).

Succinonitrile,  $\text{CNCH}_2\text{CH}_2\text{CN}$ , obtained as above and also by electrolysis of potassium cyanoacetate, is a colourless solid melting at  $54^\circ\text{--}55^\circ\text{C}$ . On reduction with sodium and alcohol it is converted into putrescine (tetramethylenediamine),  $\text{NH}_2(\text{CH}_2)_4\text{NH}_2$ , and into pyrrolidine (tetrahydropyrrole; see **PYRROLE**).

Methylsuccinic acid or pyrotartaric acid,

formed during dry distillation of tartaric acid, by heating pyruvic

acid with concentrated hydrochloric acid, or by the reduction with sodium amalgam of citraconic and mesaconic acids, is obtained in colourless prismatic crystals soluble in water and melting at  $112^\circ\text{C}$ . It forms an anhydride and its sodium salt heated with phosphorus trisulfide yields  $\beta$ -methylthiophen. Isosuccinic acid (methylmalonic acid),  $\text{CH}_3\text{CH}(\text{CO}_2\text{H})_2$ , an isomeride of ordinary succinic acid, is obtained on hydrolyzing  $\alpha$ -cyanopropionic acid,  $\text{CH}_3\text{CH}(\text{CN})\text{CO}_2\text{H}$ , or by the action of methyl iodide on ethyl sodiomalonate,  $\text{CHNa}(\text{CO}_2\text{C}_2\text{H}_5)_2$ . It crystallizes in prisms melting at  $120^\circ\text{C}$ . and is soluble in water. Unlike ordinary succinic acid, it does not yield an anhydride on heating, but loses carbon dioxide and passes into propionic acid.

See T. E. Thorpe, *Dictionary of Applied Chemistry*, vol. xi, 4th rev. ed. (1954); L. Weintraub *et al.*, "Novel Synthesis of Succinic Acid," *Chemistry and Industry*, p. 185 (Jan. 23, 1965). (G. T. M.; X.)

**SUCCULENT**, any thick, fleshy plant that is commonly juicy or sappy. Custom determines which plants are included, although for the most part succulents are native in regions that are desert or semiarid for at least a part of the year. Succulence is related to the storage of water in them. Many genera in a number of families are involved, and the individual plants may assume odd, even grotesque, forms, as in the cacti (see **CACTUS FAMILY**). Most succulents need full sun exposure and a gritty and porous soil for good drainage. A few of the genera containing well-known succulents are *Agave*, *Aloe*, *Echeveria*, *Euphorbia*, *Kalanchoe*, *Sedum*, *Sempervivum*, and *Yucca*. (J. M. BL.)

**SUCEAVA**, the capital of Suceava regiune (region) in the Socialist Republic of Rumania, lies on the Suceava River, 70 mi. (113 km.) NW of Iași (Jassy). Pop. (1963 est.) 24,856. The town was twice the capital of the historic province of Moldavia (1370–80 and 1564–68). Historical monuments include the ruined 14th-century Citadel and St. George's and St. Dumitru's churches (both in 16th-century Moldavian style). There is a museum, with important prehistoric and medieval collections, and a regional library. Chief industries are textile manufacture, timber working, and food processing.

**SUCEAVA REGIUNE** (area 5,309 sq.mi. [13,750 sq.km.]; pop. [1963 est.] 1,002,883) is about one-third mountainous (with hydropower potential) and more than one-third forested. To the east extends the Suceava Plateau and the northern part of the Jijia Depression, which is rich in chernozem. Extractive and mining industries are based on manganese, lignite, peat, and limestone. Arable land is devoted to maize (corn), wheat, sunflowers, potatoes; sugar beet, flax, and hemp. Chief towns, apart from Suceava, are Botoșani (*q.v.*), Cimpulung Moldovenesc, Dorohoi, and Rădăuți.

**SÜCHOW** (Hsü-CHOU, formerly T'UNG-SHAN), city in north-west Kiangsu province, China. Its site marks the approximate geographic border between the north China plain and the Yangtze delta plain, the meeting place of wheat and rice as staple crops, respectively. Twelve miles north is Wei-shan Hu, one of a series of long, narrow waterways into which the Grand Canal, 45 mi. E of Süchow, leads. Although walled, the city has had its historic struggles with Yellow River floods. Süchow is an important railway crossing where the north-south Tientsin—P'u-k'ou line meets the Lan-chou to Hai-chou (formerly the Lunghai) railway. This made it a strategic target during the Japanese attack on China, and at T'ai-erh-chuang, 30 mi. NE, the Chinese armies early in 1938, inflicted their first major defeat on the Japanese in a classic battle of manoeuvre that delayed the invaders' advance for two months and greatly raised the morale of the Chinese nation. A decisive battle in the Chinese civil war was also fought near Süchow from November 1948 to January 1949. Current industrial development is mainly in textiles and flour milling. Pop. (1958 est.) 710,000. (TE. H.)

**SUCKLING, SIR JOHN** (1609–1642), English poet, dramatist and courtier, best known for his lyrics, was born at Whitton, Middlesex, and baptized there on Feb. 10, 1609. He was the son of Sir John Suckling, secretary of state to James I. He was educated at Trinity college, Cambridge, to which he was admitted in 1623, and he inherited his father's considerable estates at the age of 18. He entered Gray's Inn in 1627 and left England to

travel in France and Italy in 1628. Knighted on his return in the autumn of 1630, he joined the English volunteer force raised to serve under Gustavus Adolphus and appears to have been present at the battle of Breitenfeld in 1631. He returned to London in May 1632, and became a prominent figure at court with a reputation for being "the greatest gallant of his time, and the greatest gamester both for bowling and cards." He was a gentleman of the privy chamber to Charles I and the friend of the poets Thomas Carew, Richard Lovelace and William Davenant, as well as, rather surprisingly, the famous latitudinarian divine, John Hales. When the war with the Scots broke out in 1639, Suckling raised a troop of horse at his own expense and accompanied Charles I on his ill-fated expedition. The magnificent costumes of Suckling's gaudy warriors and their poor performance in the field were the subjects of much contemporary ridicule.

In May 1641 Suckling took an active part in the plot to rescue the earl of Strafford from the Tower. When the plot was discovered, Suckling fled to France and there is every reason to believe John Aubrey's statement that he committed suicide in Paris in 1642. According to Aubrey he invented the game of cribbage.

Suckling was the author of four plays, the most ambitious of which is the tragedy *Aglaura*, magnificently staged in 1637 and handsomely printed at the author's expense (1638), and the best, the lively comedy *The Goblins* (1638). They all contain echoes of Shakespeare and Beaumont and Fletcher. Richard Flecknoe's criticism of *Aglaura* that it seemed "full of flowers, but rather stuck in than growing there" applies to all Suckling's dramatic efforts.

His reputation as a poet rests on his lyrics, the best of which justifies the description of him by Millamant in Congreve's *The Way of the World* as "natural, easy Suckling." He inherited from Donne the tradition of the "anti-platonic" deflation of high-flown love sentiment and uses it with a charming, gay insouciance in such poems as that which begins with the following lines:

Out upon it I have loved  
Three whole days together;  
And am like to love three more,  
If it prove fair weather.

"A Session of the Poets" (1637; publ. 1646) is an amusing skit for which he probably took a hint from an Italian work by Traiano Boccalini; it is the prototype of a long line of similar works in the 17th and 18th centuries. He did his best work in the manner of popular poetry. His masterpiece is undoubtedly "A Ballad Upon a Wedding," in the style and metre of the contemporary street ballad. The description of the bride has an unsurpassed delicacy and grace:

Her feet beneath her petticoat,  
Like little mice, stole in and out,  
As if they feared the light,  
But O, she dances such a way  
No sun upon an Easter-day,  
Is half so fine a sight.

Suckling's extant letters are in a lively, colloquial prose that anticipates that of the Restoration wits.

**BIBLIOGRAPHY.**—The first published collection of Suckling's works was *Fragmenta Aurea* (1646; enlarged 1658). The so-called *Selections* published by Alfred Inigo Suckling in 1836 is in reality a complete edition of the works, of which W. C. Hazlitt's edition (1874, rev. ed. 1892) is little more than a reprint. A. I. Suckling's edition includes a valuable memoir and a portrait by Van Dyck. The best modern edition is *The Works of Sir John Suckling*, ed. by A. Hamilton Thompson (1910). For anecdotes of Suckling's life see Aubrey's *Brief Lives*, ed. by A. Clark, vol. ii, pp. 240–245 (1898) and for "A Session of the Poets" and its successors, *A Journal from Parnassus*, ed. by H. Macdonald (1937). There is important biographical information in "Sir John Suckling and the Cranfields" (*Times Literary Supplement*, Jan. 29, 1960) by Thomas Clayton. (V. DE S. P.)

**SUCRE, ANTONIO JOSÉ DE** (1795–1830), was one of the most talented, successful and respected leaders of the Latin American war for independence from Spain. Born Feb. 3, 1795, at Cumaná, in eastern Venezuela, Sucre at the age of 15 was swept into the struggle against the Spaniards and loyalists and fought in many campaigns in Venezuela and Colombia. His skill and ad-

mirable character early attracted the attention of the revolutionary leader Simón Bolívar, and at the age of 26 with the rank of general, Sucre was assigned by Bolívar the mission of freeing southern Gran Colombia (Ecuador) from Spanish control. This he did by his victory at the battle of Pichincha, near Quito, in 1822.

Moving south to Peru, the central and southern portions of which formed the last stronghold of Spanish and loyalist forces in South America, Bolívar and Sucre organized an army which won the battles of Junín (Aug. 1824) and Ayacucho (Dec. 9, 1824). For his victory as field commander in the decisive engagement at Ayacucho, Sucre was given the rank of grand marshal of Ayacucho.

Early in 1825 Sucre was ordered by Bolívar to the region of Upper Peru (Bolivia) to occupy and organize the area. Bolívar joined him and the two leaders laboured to create a political structure, which took the form of a complicated constitution written by Bolívar. Under this constitution Sucre in 1826 was elected president of the new nation of Bolivia. Eager to retire from public responsibilities, he agreed to serve only two years of the lifetime tenure which he was offered. During this period Sucre attempted to provide Bolivia with institutions of government, including courts, a revenue system and schools. He sought to avoid excessive use of his great powers, but he became the target of mounting opposition born of political factionalism and ambition and complicated by Peruvian designs to absorb Bolivia. A mutiny at Chuquisaca in 1828, in which Sucre was wounded, and an invasion by Peruvian troops caused him to resign the presidency and retire to his chosen home in Ecuador. There he was called upon immediately to defend Gran Colombia against an invading force of Peruvians, whom he defeated in the battle of Portete de Tarqui early in 1829. The next year Bolívar again called Sucre from retirement, this time to preside over the "Admirable Congress" in Bogotá, a last effort to maintain the unity of Ecuador, Colombia and Venezuela within Bolívar's decade-old Gran Colombian federation. When this congress failed, Sucre started on the long ride home to Quito. At Berruecos, near Pasto in southern Colombia, he was assassinated in June 1830, probably by agents of José María Obando, an ambitious Colombian military chieftain who wished to be rid of the favourite lieutenant and possible successor of Bolívar.

Loyal, brave and modest, Sucre had been like a son or a younger brother to Bolívar, who was 12 years his senior. Among contemporaries the grand marshal of Ayacucho gained the accolade, the "immaculate Sucre," for his high moral qualities.

(T. F. MCG.)

**SUCRE** is a northeastern coastal state of Venezuela, separated from Trinidad by the Gulf of Paria. Area 4,556 sq.mi. (11,800 sq.km.), pop. (1961) 401,992. It is traversed by the northeastern highlands whose coastal range forms the two peninsulas of Paria and Araya on the east and west respectively. The eastern portion of the state receives abundant rains but the western portion, which supports most of the population, is relatively dry. Cumaná (q.v.), the state capital, is a commercial and fishing centre. Mineral resources include asphalt from Lake Guanoco, salt-works on the Araya peninsula and gypsum near Macuro. Predominantly agricultural, Sucre produces bananas, cacao, corn, cotton, rice, sugar cane, tobacco, yuca and coconuts along the coast. The fishing industry is very important. (L. WE.)

**SUCRE**, legal capital of Bolivia, and seat of its supreme court. Pop. (1962 est.) 54,270. The city (elevation 8,530 ft. [2,600 m.]) is located in a fertile valley crossed by the Cachimayo River which flows into the wide Pilcomayo, and flanked by the majestic Churukella and Sicasica Hills. Its climate is mild with an average temperature of 16° C (61° F). A variety of fruits and vegetables are grown in the valley.

Known as the City of Four Names, the city at various times was called La Plata, Chuquisaca, Charcas and finally Sucre. It was founded by Pedro de Anzures in 1538 on the site of a Charcas Indian village. Numerous churches were built, including the magnificent 17th-century cathedral the Basílica Metropolitana. In 1561 it became the capital of the Charcas *audiencia* (Upper Peru) and in 1609 the seat of an archdiocese. Its University of St. Francis Xavier, one of the oldest in South America, was founded in 1624. Sucre was an early revolutionary centre; its citizens

revolted against Spain on May 25, 1809. In 1839 it became the official capital of Bolivia and in 1840 was renamed Sucre in honour of Marshal Antonio José de Sucre, the first president of the Republic of Bolivia. In 1898 Sucre resisted efforts to move the capital permanently to La Paz and a civil war ensued. The outcome was a compromise; Sucre remained the capital in name and law but the executive and legislature moved to La Paz. (See *BOLIVIA: History*.)

A railroad to Potosí, a road to Cochabamba, a pipeline to the petroleum fields of Camiri, and secondary roads to nearby valleys made Sucre a commercial and agricultural centre of growing importance. Industrial establishments include an oil refinery and cement plant. (C. W. A.)

**SUDA LEXICON**, Greek lexicon of c. A.D. 1000. The title "Suda" is found in the manuscripts and in the earliest reference to it (in the commentary on Aristotle's *Rhetoric* by the 12th-century author Stephanus); the name "Suidas," by which the compiler is frequently known, is due to Eustathius (12th century), who arbitrarily hellenized the apparently barbarian title into a Greek (actually Thessalian) personal name.

The work is rather a combination of lexicon and encyclopaedia than a lexicon in the modern sense. It was compiled from a multitude of sources, lexicographical (principally the *Synagoge* also used by Photius, and the so-called *Lexicon Ambrosianum*), literary, biographical (principally an epitome of Hesychius of Miletus, *q.v.*) philosophical, historical, and religious. These sources were often inferior, and the compilation was prepared without adequate care or critical faculty; nevertheless, the lexicon is of immense value and is the most substantial of its kind extant. Especially important are the biographical entries on Greek classical and Byzantine writers, and the numerous quotations (over 5,000) from Aristophanes, for whose text the lexicon is an important authority.

See edition by A. Adler, 5 vol. (1928-38); Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, 2nd series, vol. 4, col. 675-717 (1931). (D. M. J.)

**SUDAN** (BILAD AS SUDAN, "country of the Blacks"), as medieval Arab writers called the area south of the Sahara, stretches for more than 3,500 mi. (5,500 km.) across Africa from Cape Verde on the Atlantic to the highlands of Ethiopia and the Red Sea, between about latitude 8° and 16° N. It borders the Sahara on the north and extends southward to the forests of West Africa and the Congo Basin. Mean annual rainfall varies between 10 in. (250 mm.) in the north and 60 in. (1,500 mm.) in the south, with the hottest months usually from June to September and a pronounced, and often very prolonged, dry season. Temperatures are generally high throughout the year. Vegetation ranges from semidesert steppe and thorn-scrub near the Sahara through vast grass plains, loosely termed savannas, with numerous varieties of acacia and mimosa, to parkland country where low trees grow among tall grasses, and savanna forest that merges ultimately into equatorial rain forest.

During the dry season the trees shed their leaves, all but the largest rivers run dry, and bush fires which burn up the grass are common. Relative humidity may fall as low as 30%. The rainfall might be adequate for cultivation were it not for the very high rate of evaporation which makes irrigation essential in many areas.

Much of the Sudan is a plateau between 1,000 and 1,500 ft. (330-415 m.) above sea level, but there are many higher areas, sometimes exceeding 10,000 ft., as in northern Ethiopia and in the west of the Republic of the Sudan (Darfur). The principal rivers include the Senegal and Niger, draining to the Atlantic, and the Nile and its tributaries which derive much of their water from areas beyond the Sudan region. Lake Chad (*q.v.*) is a centre for interior drainage.

There has been considerable admixture with Hamitic peoples, the degree of Hamitic influence decreasing westward and southward toward the Gulf of Guinea. Many of the people are Muslims.

The density of population is generally low and many of the people are nomadic or seminomadic. Movement across the grasslands is generally uninterrupted, especially during the dry season and the continuity of a similar environment along the southern

boundaries of the Sahara for vast distances has encouraged people to move from the north and east from early times. At first they traveled with the aid of horses and oxen but migration was greatly expanded and probably accelerated with the introduction of the camel in about A.D. 300, especially as camel caravans were able to cross the Sahara. Thus the Sudan was linked with the Mediterranean coastlands whose manufactured articles, together with Saharan salt, were exchanged for the gold, kola nuts, and slaves of Guinea.

From Arab historians something is known of some of the powerful states that were established by military rule, the largest and most enduring of which were associated in the western Sudan with the termini of the desert trade routes. Ancient Ghana was created by Jewish or Berber settlers about A.D. 300 in the area west of Tombouctou (Timbuktu), though its greatest years came when it was ruled by the Negro Sarakolé dynasty (see GHANA [ANCIENT]). Almoravid attacks in the 11th century reduced its power and led to its replacement by the Mali or Mandingo Empire, centred on the upper Niger. Mali in turn was overthrown during the latter part of the 15th century by the expansion of the Songhai or Gao Empire that developed from Berber settlements established on the lower Niger as early as the 7th century. In 1591 the Songhai towns of Gao, Tombouctou, and Jenné (Djenné) were occupied by Moroccan troops anxious to control both the lucrative caravan traffic and the long-established trade in gold. The empire was replaced by numerous Negro kingdoms, including the Mossi-Dagomba states, the Bambara kingdoms of Ségou and Kaarta, Bornu, and the small Hausa states that were later conquered by the Muslim Fulani early in the 19th century. European penetration was followed by the establishment of political control, principally that of the French and the British, which lasted until the emergence of independent states during the 1950s.

On the eastern side of the continent Egyptian links with the Sudan region were generally strong, notably with Nubia. After the Nubian Empire had been overrun by Muslims it was replaced by kingdoms such as those of Dongola, Darfur, and Sennar. Later there was invasion from Egypt and, in 1899, the establishment of the Anglo-Egyptian condominium. The independent Republic of the Sudan was created in 1956.

See CENTRAL AFRICAN REPUBLIC; CHAD, REPUBLIC OF; MAURITANIA, ISLAMIC REPUBLIC OF; NIGER, REPUBLIC OF THE; NIGERIA; MALI, REPUBLIC OF; SUDAN, REPUBLIC OF THE; UPPER VOLTA, REPUBLIC OF THE; NUBIA; see also references under "Sudan" in the Index. (R. W. SL.)

**SUDAN, REPUBLIC OF THE** (JUMHURIYAT AS SUDAN), an independent country of northeast Africa, bounded by Libya on the extreme northwest, by the United Arab Republic (Egypt) on the north, by the Red Sea and Ethiopia on the east, by Kenya, Uganda, and the Democratic Republic of the Congo (formerly Belgian Congo) on the south, and by the Central African Republic and the Republic of Chad on the west. Area 967,491 sq.mi. (2,505,805 sq.km.). Pop. (1955-56) 10,262,536; (1964 est.) 13,011,000. The Sudan was from 1899 under the joint sovereignty of Great Britain and Egypt and was known as the Anglo-Egyptian Sudan until its independence in 1956. The name Sudan is derived from the Arabic expression *Bilad as Sudan* ("country of the Blacks") which originally applied to a much wider area of Africa. The capital is Khartoum (*q.v.*).

## I. PHYSICAL GEOGRAPHY

**1. Relief, Drainage, and Geology.**—The Sudan is mainly made up of vast plains and plateaus drained by the Nile and its tributaries. The wide basin is bounded on the east by the Red Sea Hills (over 7,000 ft. [2,100 m.]), to the southeast by the Ethiopian Highlands and on the west by the Jabal Marrah group (highest peak 10,134 ft. [3,089 m.]), which rises over a lower rounded divide between the Nile and Chad basins, and, in the southwest, the Nile and Congo basins.

The Nile system is the dominant physical feature. The White Nile (Al Bahr al Abyad), entering the country as the Bahr el Jebel from the south through rapids at Nimule, has a very low gradient until it is joined by the Blue Nile (Al Bahr al Azraq) at Khartoum. The Blue Nile contributes most of the floodwater as much of the White Nile flow is lost in the sudd (swampy) region, and about half of its discharge to the north is from the Sobat, which, like the Blue Nile, rises in the Ethiopian Highlands. Throughout much of the country drainage does not reach the Niles; the rivers of the southwest infrequently reach the Bahr el Ghazal system, and to the north most hill groups initiate seasonal watercourses which are lost in the surrounding plains. An important inland delta is that of the Gash near Kassala. (See NILE.)

Igneous and metamorphic rocks of the Precambrian Basement Complex series underlie much of the Sudan and appear at the surface in the Red Sea Hills, the Nuba Mountains (Jibal an Nubah), the southern plateaus, and in scattered hills over the plains. Mesozoic Nubian sandstones unconformably overlie the older rocks over the northwestern Sudan and in the Gedaref area in the east. In Tertiary times volcanic outbursts gave rise to the Jabal Marrah group and to the many scattered volcanic hills of the northwest. Later events include the formation and alluvial infilling of the large depression (1,000 ft. [305 m.]) in the region of the White Nile (Umm Ruwabah series) and of a smaller depression (200 ft. [60 m.]) along the Blue Nile.

The northern region, between 16° N and the frontier (22° N), is a sand- or gravel-covered desert, diversified by the typical flat-topped *jabals* of Nubian sandstone and the islandlike steep-sided granite hills of the Basement Complex. To the south lie the great plains and plateaus of the Sudan. In the west these show evidence of former more arid climates in the relict, now stable, sand dunes and sheets of Kordofan. To the east the desert is replaced by clay plains at about the latitude of Khartoum extending southward to about 6° N and across the Nile into Bahr el Ghazal and Equatoria provinces. The soils on the clay plains are heavy and sticky during the rains but dry and cracked during the rest of the year. In the extreme south, tropical red earths and ironstone outcrops occur, particularly to the west of the Nile. Little percolation occurs in the clay plains and underground water is not easily obtained. The Nubian sandstone is the best aquifer where rainfall is sufficient or where water percolates from the Nile. Elsewhere local wells and bores are found near the foot of the scattered hill masses. Several streams in the Red Sea Hills have an appreciable flow, and Khor (Khawr) Arba'at supplies Port Sudan with surface and underground water.

**2. Climate.**—North of about latitude 19° N northerly winds prevail for most of the year and rainfall is rare; to the south of this

the seasons are characterized by the oscillation, north and south, of the boundary between moist southerly air and dry northerly air. Abu Hamad is the normal northern limit of the rains; a short wet season at Khartoum provides an average rainfall of 7 in. (180 mm.); there is 15 in. (380 mm.) at Wad Medani (Wad Madani) and 50 in. (1,260 mm.) at Gambela (a Sudanese trading station inside Ethiopia). Most of the rainfall occurs in heavy thundery showers. Except for the Red Sea coast, where the most rain comes in autumn, 50-75% of the precipitation occurs in the three summer months, although at Juba in the far south there are only two really dry months.

Highest temperatures, which usually precede the rains, occur in July in the extreme north, in May-June in Khartoum, and in April, March, or February progressively farther south. A maximum of 52.2° C (126° F) has been recorded at Wadi Halfa and 47.2° (118°) at Khartoum, but in the south temperatures reach only 42-43° (108-109°). Haboobs (dust storms) occur in the northern and northeastern Sudan.

**3. Vegetation.**—Five major vegetation types can be distinguished: (1) the sparse desert vegetation of the north; (2) a zone of semiarid acacia scrub and short grassland farther south; (3) the woodland savanna of most of the southern half of the country; (4) the vegetation of the floodlands and swamps of the Nile and (5) the flora of the mountain regions.

The desert, with less than 3 in. rainfall, supports permanent vegetation only near watercourses. Date palms are frequent along the Nile, and the doum palm, tamarisk, and coarse grasses are found where the banks are not cultivated. The semidesert (3-11 in. [76-280 mm.] rainfall) includes the Red Sea coastal plain and a zone running east-west across the country roughly between the latitudes of Atbara ('Atbarah) and Wad Medani. Vegetation there is characteristically a mixture of grasses and herbs with scattered scrub and bare areas. *Acacia tortilis* is common, though not on clay soils, and *Blepharis* species with areas of grasses is the typical climax vegetation. On sands other acacias are more frequent. The woodland savanna—a mixture of grasses, bushes, and

SUDAN SURVEYS

MAP OF THE REPUBLIC OF THE SUDAN SHOWING PROVINCES AND MAIN TOWNS

trees—has several distinct subdivisions. In the areas of the north where the rainfall is less than 30 in. (760 mm.) trees are thorny and acacias dominant. On the eastern clays *Acacia mellifera* is found merging into *A. seyal* in the south, while the Qoz (Qawz) sands support *A. senegal* (yielding gum arabic) and, in depressions between the dunes, baobab. With increasing rainfall *Combretum cordofanum* woodland develops with grasses, and in the wetter areas the natural vegetation would be the rain forest now found only in a few remnants. *Khaya*, or African mahogany, *Isobrerlinia doka*, and *Anogeissus schimperi* are characteristic trees in the drier areas; *Terminalia glaucescens*, *Albizia zygia*, *Vitex doniana* are among the larger trees found in wetter parts. Elephant grass is common. In the Nile Valley north of Juba and the widening swamps (sudd) to the north, papyrus is common along the waterways but grasses and the water plant *Pistia* are also important. The water hyacinth spread rapidly from 1957, infilling many of the side channels and lagoons. In each of the mountain groups, Jabal Marrah, Red Sea Hills, Imatong, Dongotona, and Didinga, distinctive assemblies and vegetation zones are found.

**4. Animal Life.**—The southern Sudan is one of the areas in Africa where the characteristic wildlife may be seen best. Most of the grassland animals (lion, leopard, cheetah, giraffe, zebra, antelope, etc.) are common; buffalo, hippopotamus, chimpanzee, and baboon are also abundant among a wide range of other species. Common birds include guinea fowl, bustards, geese, cranes, storks, pelicans, weaver birds, shrikes, and starlings. The rare shoebill is found in the Bahr el Ghazal region. Crocodiles are numerous on the Nile and many types of land lizard are found. Snakes are not abundant but many are poisonous. Mosquitoes are abundant on the rivers and blood-sucking horseflies are locally common. The tsetse fly occurs south of about 12° N.

**National Parks.**—There are 3 national parks, 14 game reserves, and 3 sanctuaries in the country. The Dinder (2,470 sq.mi. [6,397 sq.km.]) contains much game, while the Southern National Park (6,500 sq.mi. [16,835 sq.km.]) and the Nimule National Park provide sanctuary for elephant, white rhinoceros, buffalo, and the giant eland. (L. Be.)

## II. GEOGRAPHICAL REGIONS

Twelve regions may be distinguished:

1. The ironstone plateau of the south and southwest is largely forested. Along its northern margin, west of the Bahr el Jebel (Bahr al Jabal), Nilotic tribes, chiefly the Dinka, occupy their villages during the rainy season, when they graze their cattle and grow food crops. Farther south, and nearer to the international frontiers, agricultural tribes (or parts of tribes), practise shifting cultivation. Much of the centre and west is uninhabited.

2. The plateau of Darfur is remarkable for seasonal watercourses radiating from the Jabal Marrah. These have attracted almost all the permanent settlement in the province because of the proximity of cultivable land and the availability of water in wells after the rains. Between the main valleys the thin infertile soils of the plateau are lightly wooded and during the rainy season thickly carpeted by grass. Nomadic tribes graze their animals widely, but remain near the main watercourses during the dry season.

3. Jabal Marrah, and associated uplands, between 3,000 and nearly 10,000 ft. (900–3,000 m.) above sea level, are rugged and difficult of access. They are occupied by the Fur people who live in small villages and scattered farms. The Fur divert mountain streams into small gardens, make terraced fields and keep cattle, which they pen on their arable land after harvest.

4. The great clay plain is divisible into two parts. The southern and larger part is occupied by cattle-owning Nilotic tribes, who retreat to the margins or to small areas of relatively high land during the rainy season, when almost the entire surface is submerged. In the dry season they drive their herds to moist grazing close to the permanent rivers. The northern part receives less rain and therefore does not become a swamp in the rainy season, although at times movement is difficult. Bisected by the Blue Nile and bordered on the west by the White Nile, this part is sparsely inhabited in the south, but in the centre and along the two

Niles a large population is supported both by cultivation depending on rain and by projects based on irrigation, growing cotton as the chief cash crop. The largest of these irrigation projects is the Gezira (q.v.). More developed economically than other parts of the country since 1900, its population has increased rapidly and it has received many immigrants from the north and west. Also, it has a higher proportion of urban population. Farther north, where rainfall is still lower, agriculture gives way to nomadic grazing.

5. The eastern frontier, in principle, lies at the foot of the Ethiopian uplands; but locally, between the Atbara ('Atbarah) River and the Blue Nile near the Sobat River and in the far south-east, foothills or detached small uplands lie within the Sudan. All these areas are remote and have small populations.

6. The dunes (Arabic, *qoz*, or *qawz*) form a zone about 750 mi. (1,200 km.) long, from the White Nile to southern Darfur, and 125–250 mi. (200–400 km.) wide. Except along the northern fringe, it receives sufficient rainfall for agriculture; but tilled lands are discontinuous, because of lack of water supplies. South-west Kordofan and much of eastern Darfur are used mainly by nomad cattle-owning pastoralists.

7. The Nuba Mountains, with the tableland from which they rise, are comparatively well populated. The Nuba peoples are expert at cutting rock cisterns in the veins of rotted granite, and sink wells at suitable places at the foot of the scarps. They have long been established in hill villages, surrounded by small terraced fields, and have been encouraged to settle in the piedmont areas and to cultivate more land, chiefly for cotton, in areas of silty soil.

8. The Red Sea Hills are near-desert except in the extreme south, and are occupied by the nomadic, camel-rearing Beja tribes.

9. The Red Sea coastal plain is also a near-desert and has practically no settlements except for Port Sudan (which depends for its water upon wells sunk in the bed of the Khor [Khawr] Arba'at, nearly 30 mi. [48 km.] N) and Tokar (Tawkar).

10. The semidesert zone is arid, but the slight rainfall sustains a sparse and discontinuous vegetation (chiefly in watercourses) which is grazed by camel-owning nomads.

11. The desert, in the northwest, is rainless, completely unproductive, and uninhabited.

12. The Nile Valley below Khartoum is a nearly continuous ribbon of land irrigated by the ancient shadoof (*shaduf*) and sakieh (*saqiya*) methods (see EGYPT: *The Economy: Methods of Agriculture*) and the modern pump. It supports a peasant population, living in villages between the sown land and the desert behind, and several large towns, including Shandi, Atbara, Berber (Barbar), and Wadi Halfa. (J. H. G. L.)

## III. THE PEOPLE

The inhabitants of the Sudan are of widely varying ethnic origin. The republic is roughly divisible into the Muslim Arabic-speaking north and the pagan, partly Christianized, south, the boundary being the line of the Bahr al 'Arab (at about 10° N latitude). The amount of internal migration creates overlaps, but in the north only the pocket of Nuba, in the Nuba Mountains, is pagan. Physically the northerners are mostly of the stock generally called Semitic, although people of the types usually classified as Hamitic (the Beja tribes) are found in the east. Southerners are Nilotic (including Nuer, Dinka, Shilluk), Negroes (Azande, etc.), and Nilo-Hamites (Bari, etc.).

**1. Tribal Groups.**—Apart from the large agglomeration of the Three Towns (Khartoum, Khartoum North, and Omdurman) and of Port Sudan, the country is fairly described as rural and tribal although there are sizable market towns and administrative centres throughout.

The northern and central rural populations can be divided into nomadic camel owners, nomadic cattle owners, settled cultivators, riverain peoples, and participants in one or another of the rural development projects. The nomadic camel owners are mainly Kababish (q.v.), Kawahla, Hawawir, and Zaghawa (q.v.) of Kordofan and Darfur provinces and the Beja (q.v.; including the Hadendoa, or "Fuzzy Wuzzies") and the Shukria Arabs of

Kassala Province. The cattle-owning nomads are the Baggara (*q.v.*), or Baqqara, Arabs, comprising many different tribes who extend in a central belt westward from the White Nile through Darfur as far as Lake Chad but who share a similar way of life. The camel nomads and the Baggara each belong to tribes whose members regard themselves as being related to one another patrilineally. They move their herds each year over much the same ground, seeking the grass within their circumscribed tribal territories.

Between the camel and cattle owners there lies a belt of settled cultivators who depend on millet or the sale of gum arabic for their livelihood. The Nubians and Barabra (*q.v.*) of the Nile Valley grow and sell dates and export labour to the towns, largely in the form of domestic service, although many merchants in the towns and in tribal markets are Nubian in origin. They are forced out of their land by the continual fragmentation on inheritance of the small available riverain estates.

The development of the Gezira Plain, as well as the Baraka and the Gash projects and the new Khashm al Qirbah (el Girba) project on the Atbara River, afford poor rural populations some profit from cotton and other crops.

In the south the cattle folk (notably the Nuer and Dinka [*qq.v.*]) are the most numerous. Their climate is wetter and they move about less than the northern husbandmen. The difficulty in gaining access to the swamp land as well as the people's own resistance has delayed the development of this part of the country, although the Dinka are better educated and are more inclined to seek work in towns than are the Nuer. The Bari (*q.v.*), once primarily pastoral, were forced into a greater dependence upon agriculture by depredations in the 19th century.

**2. Languages.**—Arabic, the official language, was claimed at

the 1956 census by more than half of the total population at their native tongue although it is spoken with considerable dialect variations. English is a common alternative. The Beja, Nuba, and some peoples of Darfur are large groups in the north with languages of their own, although many of them speak fluent Arabic as well (see NUBA; NUBIAN LANGUAGE AND WRITING). The south has a great language mixture, Dinka (over 1,000,000 speakers), Nuer (500,000), and Zande (250,000) being the languages most spoken. (See also SUDANIC LANGUAGES.)

**3. Religion.**—An estimated two-thirds of the population mostly in the northern and central areas, profess Islam. There is a broad division on religious grounds between the followers of the Mahdi (*q.v.*) and his successors (largely accounted for by the western nomadic tribes) who follow an austere brand of Islam, and the rest. The leaders of the Mahdists, and the next most important sect, the Khatmiya, became leaders of rival political parties that emerged before the Sudan's independence in 1956.

Pagan religions predominate in the south though there are considerable numbers of Christians (Catholic and Protestant), and since independence Islam has been making headway. Cattle plays an important part in the religions of the Dinka and Nuer. The Azande (*q.v.*), who inhabit the Congo border, are known for their remarkable system of oracular divination, which regulates much of their daily lives. (See also *History*, below.) (I. C.)

**4. Population Distribution.**—The population of the Sudan, 10,262,536 at the first census in 1956, was estimated at 13,011,000 in 1964, an average annual increase of over 3% since 1956. The mean density is slightly more than 13 per sq.mi. (about 5 per sq.km.). Less than 10% of the population lives in urban centres, the largest of which are the Three Towns (Khartoum, Khartoum North, and Omdurman), Wad Medani, and El Obeid (Al Ubayyid) in the central Sudan; Port Sudan on the Red Sea and Atbara in the northern Sudan; Kassala in the northeast on the Eritrean border; El Fasher and Nyala in Darfur; and Malaka and Juba in the southern Sudan. Approximately a quarter of the country is completely uninhabited, including the desert in the north and northwest, a large area in the southeast divided between Upper Nile and eastern Equatoria provinces, and tracts in central and western Bahr el Ghazal. About a third is used only by migratory pastoralists. The areas containing a settled population account for less than a half of the total area and comprise, in order of importance: (1) the central rain lands, between about 10° and 15° N; (2) the southwestern margins of the southern clay plain and the adjoining fringe of the ironstone plateau; (3) the agricultural belt in the far south, close to the borders with the Republic of the Congo and Uganda; (4) the Nile Valley below Khartoum; (5) the areas containing patches of high land close to the Bahr el Jebel, the White Nile above Melut (Malut), and the Sobat, on which the eastern Dinka, Nuer, and Shilluk (*q.v.*) have their villages. In the mid-1960s, about 60,000 inhabitants from the Nile Valley villages (which were to be submerged by the lake forming behind the Aswan High Dam) were moved to the new irrigation area near Khashm al Qirbah in the Atbara Valley.

The extent of migratory modes of living is remarkable. About 14% of the population is wholly nomadic. These people live in the northern Sudan and include the Beja tribes of the Red Sea Hills, Arabs of northern Kordofan and Darfur, and the Baggara of south Kordofan and southern Darfur. The Nilotic tribes of the southern clay plain, although possessing permanent villages, normally migrate during the dry season for distances of from 5 to 50 mi. Some of the agricultural tribes living close to the southern and eastern frontiers practise shifting cultivation and abandon their old homesteads for new after a period varying between 5 and 15 years. Many cultivators in the central rain lands migrate during the dry season because local water supplies fail. Altogether, it can be estimated that nearly half of the population is migratory in varying degrees; and only slightly more than half is fully settled.

Tribal grouping is also very diverse. More than 570 tribes and many subtribes were registered at the 1956 census. Arab tribes accounted for about two-fifths of the population, but some other groups were also large. In northern and central Sudan the Arab

tribes (Ga'alín, Guhayna, Baggara, and others) formed 39% of the population. Other major groupings were the Nuba (6%), the Beja (6%), and the tribes of western Darfur (9%). In the southern Sudan, the Dinka accounted for 8%, Azande for 2%, and Bari for 2%. An interesting indication of the sparse population was the presence of about 500,000 "westerners" from the countries that were formerly part of French Equatorial and West Africa who were settled in Darfur, parts of Kordofan, and the Blue Nile Province. In the east, they were attracted by unused agricultural land and the demand for labour in agricultural projects. Some were Sudanese nationals, and altogether they comprised about 5% of the 1956 population. (J. H. G. L.)

#### IV. ARCHAEOLOGY

With minor exceptions, it was only in the northern Sudan, where expeditions from many countries, all working under the auspices of UNESCO, were excavating sites doomed to be flooded by the Aswan High Dam reservoir, that there had been any scientific excavations by the mid-1960s (*see* NUBIA). Elsewhere in the Sudan archaeology remains in its infancy. No thorough archaeological surveys have been made, though from surface finds and from the observations of officials and others certain general lines are beginning to emerge. Roads by which foreigners obtained the products of the Sudan (particularly slaves, gold, and ivory) were always of paramount importance.

In the upper valley of the Atbara River in the eastern Sudan, fossils and Lower Paleolithic implements have been found, indicating one route by which the early Stone Age cultures of Egypt and east Africa were connected. In the desert in the northeastern Sudan gold was extensively mined from ancient Egyptian times down to the 11th century A.D. Stone-built huts, stone mortars, hammers, and circular grinding mills occur with pots at the ancient mines. The most important route in this area from the earliest historic period has been that which gave access from the Red Sea (south of Port Sudan) to the central Sudan by a route which passed north of the Ethiopian Massif to the Kassala area. The earliest pottery known in the Sudan, associated in the Khartoum area with barbed bone harpoons, has been found as far east as Kassala and as far west as Wanyanga (Ounianga) in Borku. From Qoz Regeb (Qawz Rajab) has come evidence of occupation from the protodynastic to the Christian period; and at Sarsareib and in the Kassala area are sites dating back to protodynastic and possibly earlier times. In the Red Sea Hills there are early occupation sites at Agordat in Eritrea (C Group and Pan-Grave) and at Erkowit. At 'Aqiq on the Red Sea coast are remains suggesting that this was the site of Ptolemais Therion, whence the Ptolemies obtained elephants for their army and which probably continued as a trade centre until the Aksumite period. In Roman times trade with India diverted attention from the African mainland; but Meroe and Aksum became affected by influences from India as a result of the development of that trade, and it was probably trade rivalry that led Aksum to destroy a degenerate Meroe c. A.D. 350. Early in the Muslim era Ptolemais was overshadowed by Badi on Airi Island (Jazirat ar Rih), where there is a ruined town with cisterns and where Muslim tombstones dating from the 10th and 11th centuries have been found. Similar tombstones dating from the 8th to the 10th centuries (the earliest is A.H. 153 = c. A.D. 790) have been found in Khawr Nubt, while early Muslim stone-built towerlike tombs occur at Ma'man east of Kassala and elsewhere. Circular stone graves with flat tops are probably those of the Muslim Beja.

In the Blue Nile Valley of the central Sudan fossils are found below the clay of the Gezira Plain, notably at Abu Hugar and Sinjah, where they include a proto-Bushman skull, contemporary with a crude Levalloisian culture. Ancient Egyptian expeditions must have penetrated far south of that part of the Nile Valley occupied by them during the New Kingdom. One such expedition to localities previously unidentified is recorded by Amenhotep II, one of whose scarabs was found 100 mi. E of Khartoum. The Blue Nile Valley from Khartoum to Er Ruseres (Er Roseires; Ar Rusayris) was no doubt always the road to Beni Shangul (Ethiopia), whence came slaves and gold. Occupation sites occur all

the way to Er Ruseres, and no doubt the Napatan, Meroitic, Christian, and Fung (Funj) periods are represented. In the 6th century A.D. Aksum was trading with this area directly, bartering gold for iron at Fazughli. Finds of Napatan date were made at Sennar and Kosti, while at Moya (Jabal Mayyah) Sir Henry Wellcome excavated an occupation site and cemetery showing Negroes' trade connections with Napata. Finds of Meroitic date were made in and near Sennar. Rock pictures from this period occur at Geili (Jabal Jayli) east of Khartoum; and the artificial water reservoirs which are common as far south as the Jabal Mayyah area are probably the work of the kingdom of Meroe. A Meroitic ram, brought from Soba (Sawba) to Khartoum by Gen. C. G. Gordon, indicates that Soba was probably a Meroitic town before becoming the capital of the Christian kingdom of Aloa. Little now remains on the surface at Soba but red-brick fragments and the stone capitals of a Christian church; Old Nubian inscriptions have been found there in the past. Christian sites are reported from the Blue Nile between Khartoum and Sennar and from al Geteina (Qutaynah) on the White Nile. At Sennar the site of the Fung capital (A.D. 1500-1821) is being destroyed by the river. At Abu Jayli near Sennar, a site excavated for Wellcome in 1912, Fung pottery was recognized with considerable probability.

South of Kosti, occupation sites in the southern Sudan occur along the bank of the White Nile as far as Malakal. Shards of apparently early date have been found near Malakal, Doleib Hill, and Jabal Zaraf al Azraq, and a microlithic culture of Wilton type with pottery on Belli Island. Shards from a pre-Shilluk site near Kaka suggest a connection with Sennar and Meroe. Ancient occupation mounds have been reported from the Bahr el Ghazal in Aweil district, and polished celts of hematite near Yambio. This southern region must long have been the goal of traders seeking slaves and ivory, and copper mining probably began at Hofrat el Nahas (Hufarat an Nahas) at an early date. The Azande show evidence of cultural contact with ancient Egypt, and the Masai and the Kikuyu of East Africa seem to appear more than once, in scenes representing the arrival of the tribute of Cush, in the Tombs of the Nobles at Thebes.

In the western Sudan the most important road is that which runs west from the White Nile between the desert and the tropical forest through Darfur and past Lake Chad to West Africa. A few roads running north to south across the desert follow lines of water holes and link this great road with the North African coast. In early times the steppe country extended farther north, and finds of protodynastic date come from the southern Libyan desert. It may be that Tibesti is the source of the amazon stone common to the Neolithic cultures of the Fayyum and Shaheinab. From Wadi Howar come remains which suggest that the cattle-owning C Group people, first known to archaeologists in lower Nubia, once lived there. The 6th-dynasty inscriptions on Harkuf's tomb at Aswan suggest that the ancient Egyptians used donkey caravans on the Darb al Arba'in. The earliest traditional rulers of Darfur were the Dagū (otherwise Daju, Tajo, Tago), and some of the brands used till recently by the Dagū sultans of Dar Sila may have a hieroglyphic origin. The extent to which the ancient Egyptians and, later, the kingdoms of Napata and Meroe controlled the great east-west road is unknown.

Meroitic "archer's looses" were found in Darfur and at Jabal Harazah. That, after the fall of Meroe itself, the Meroitic royal family may have carried on in the west is suggested by an Old Nubian graffito at Audun, a tumulus near Kabeiya in Jabal Maydub (said to be the grave of a queen who brought the Meidob-Kagiddi people from the Nile) and also by the survival of Kash (Cush), the old name of the kingdoms of Napata and Meroe, in the modern tribal names Kagiddi, Kaja, and Kajar (Birgid).

There are many stone-built ruins in the hills of Darfur. A few are attributed to the Dagū. The red-brick ruins at 'Ein Fara ('Ayn Fa'rah) in northern Darfur were proved to have been a monastery and two small churches (one, domed), indicating that between the 9th and 13th centuries, if not earlier, Darfur was within the sphere of influence of the Christian kingdom of Mukurra (from which the tribal name Tungur is derived). That sphere probably once extended as far as Lake Chad. The fine date palms

and hill-terracing near 'Ein Fara suggest that the Tungur originated the excellent terracing and good agriculture of the Darfur Hills. They still maintain their connections with the Bideyat (Bedyat) of the Ennedi Plateau (who were once Christian). The walled stone town containing two royal residences at Jabal Orrei (Uri) probably dates from the same period. Rock pictures of horsemen in the Tungur Hills (Jabal Tungwa) and at Jabal al 'Afarit in Kordofan are probably crude copies of Christian saints on horseback as represented in the church of Abd al Qadir at Wadi Halfa. The red-brick ruins at Abu Sufyan and Jabal Zankor in northern Kordofan no doubt date from this period, and there are rectangular stone Christian graves in the Wadi Muqaddam. The influence of Christian Nubia in Darfur must have been destroyed by the advancing power of the Muslim kingdom of Kanem, which by A.D. 1240 controlled the trade route between Kanem and Nubia. From that date to the 16th century, the influence of the medieval kingdom of Bornu was predominant in Darfur and Kordofan and is responsible for the many stone compounds between Kordofan and Dongola, and no doubt for some stone buildings in the Darfur Hills. The most recent stone forts in Turrah at the northern end of the Marrah Massif are traditionally associated with the early Fur sultans. See also EGYPT: *Archaeology*. (A. J. AL.)

## V. HISTORY

**1. Early History.**—The southern Sudan has no recorded history until the 19th century A.D. although the equatorial regions were vaguely known to ancient Egyptian, Greek, and Arab geographers. The northern Sudan first came under the influence of Egyptian culture c. 3000 B.C. and was actively occupied by the Egyptians between 2150 B.C. and 1580 B.C. A native power subsequently arose with its capital at Napata (*q.v.*), near the Fourth Cataract of the Nile, whose rulers conquered and held Egypt itself from c. 730 B.C. to 660 B.C. The capital was transferred c. 590 B.C. to Meroe (*q.v.*) near the Sixth Cataract, and the following centuries saw a growing isolation from Egypt. The Ptolemaic and Roman rule in Egypt made little permanent impression on the Sudan.

By c. A.D. 500 three kingdoms had emerged: Nobatia, with its capital on the present Sudanese-Egyptian frontier; Mukurra (Muqarra), the central kingdom, with its capital at Old Dongola (see DONGOLA); and Alodia (Aloa), the southernmost kingdom, centred on Soba at the junction of the Blue and White Niles. The people of all three were called Nubians by contemporary writers. The unsettled state of the frontier probably explains why Christianity did not penetrate Nubia until the 6th century, at a time when the eastern Roman Empire was beset by theological disputes. Julianus, a missionary from Alexandria, converted the Nobatae to monophysite Christianity c. 543 and Longinus, who had been sent as monophysite bishop of Nubia, converted the Alodians, while the middle kingdom seems for a brief time to have received the Orthodox faith.

The conquest of Egypt in 640–641 by an Arab army commanded by 'Amr ibn al-'As brought triumphant Islam to the northern border of the Sudan and isolated the people from the political and religious influence of Constantinople. In 651–652 'Abdullah ibn Sa'd, Arab governor of Upper Egypt, invaded Nubia and made a treaty with the Christian ruler.

After 700 years of relative prosperity followed by slow decline, the power, and finally the existence, of the Christian states on the Nile were brought to an end, probably in the 14th century. So long as Egypt remained under Arab domination, Muslim relations with the Christian kingdoms were usually friendly, but after the Arab governors had given place to non-Arab mercenaries, and later to the Mamelukes, relations with Egypt deteriorated. Arab tribes, chiefly Guhayna, edged out of Egypt by the foreign yoke and fleeing from uncongenial settled government, infiltrated into the Christian Nile Valley and the broad savanna country of the central Sudan. The Arabs intermarried with the local Nubians and Beja and gradually obtained control, though both Nubians and Beja largely retained their own languages. The southernmost kingdom of Alodia, later known as 'Alwa, survived for a longer time, though fixing the time and circumstances of its fall is difficult.

The origin of the Fung, or Funj, sultanate which rose on the ruins of the Christian kingdoms has long been the subject of controversy. Various theories connect the foundation of this state with immigrants from the White Nile area, Ethiopia, and Bornu. The ruling body seems to have been Muslim from the beginning of the sultanate, though sultans and subjects retained pagan practices. Arabic was the language of administration. The sultans directly ruled only the Gezira (Jazirah), the peninsula between the Blue and White Niles, while the country immediately to the north was administered by 'Abdullah Arab viceroys who had their seat at Qarri at the Sixth Cataract (Shallal as Sablukah). The rest of the sultanate was governed by autonomous tribal chiefs, the more important of whom received the title of *manjil* and were invested with a ceremonial stool and distinctive two-horned head-dress, symbols of the sultan's warrant.

The Fung sultanate was brought early into contact with the Ottoman power which conquered Egypt in 1517. The Turks planted garrisons of European Muslim troops in fortresses at Aswan, Ibrim, and Sai Island (Jazirat Say) and at an unascertained date defeated a Fung army at Hannek. The Turkish garrisons mingled with the local inhabitants and modified the racial type. During the reign of the Ottoman sultan Suleiman I, 'Ozdemir Pasha, beylerbey of Yemen, occupied the ports of Suakin and Massawa which became the chief towns of the Ottoman coastal province of Habash. Trade appears to have been an important concern of the Fung sultans who, however, struck no coins. The earlier sultans were munificent patrons of Muslim scholars and saints whose mysticism gave Sudanese Islam its distinctive character. About 1680 the Fung confederacy was weakened by a revolt of the Shayqiyah (Shaikia, or Shagia) tribe in the north, and a general decline in the administration set in during the 18th century. In 1789 chiefs of the Hameg (*q.v.*; or Hamaj), a people of indeterminate origin, usurped the government, and the sultanate relapsed into political fragmentation. In 1812 Dongola was seized by Mameluke fugitives from Mohammed Ali's massacres in Egypt. By 1820 the anarchic condition of the northern Sudan made it an obvious objective for foreign invasion.

**2. Egyptian Occupation, 1820–81.**—For the next 60 years the Sudan was governed as a dependency of Egypt under the nominal suzerainty of the Ottoman Empire. The Egyptian penetration was effected in 1820–21 by two invading columns. The first, commanded by Ismail, third son of Mohammed Ali, ascended the Nile Valley, defeated the Shayqiyah, and entered Sennar on June 14, 1821. The second column, under Mohammed Bey Khusrav, followed up the Nile in the spring of 1821, left the valley at Dabbah, and marched southward over the Bayudah Steppe to Barah in Kordofan, where the Egyptians defeated Musallim, the Darfur regent of Kordofan, on Aug. 16. On Aug. 20 they entered El Obeid. Ismail's murder by a Sudanese chieftain at Shendi in October 1822 was the signal for a desperate Sudanese revolt which involved all the tribes from Berber to Sennar. The revolt was bloodily suppressed by Mohammed Bey with a force from Kordofan. In 1824 'Osman Bey, military commander of Sennar, built a fort at the village of Khartoum which became the seat of government.

After five years of military misrule and savage taxation, 'Ali Khurshid Pasha was sent to the Sudan in 1826 as its first governor-general with full military and civil powers. He converted Khartoum from a military headquarters to an administrative capital, put the administration on a sound footing, and conscientiously attempted to carry out Mohammed Ali's plans for economic development. He persuaded many Sudanese fugitives from Egyptian maladministration to return to their lands, but the Ethiopian ruler of Gondar resented his aggressive frontier policy and there was fighting in 1836–38. Khurshid was recalled in 1838 after proving himself an able administrator by the standards of the time. His successor, Ahmad Pasha Abu Adhan, who held office from 1838 to 1843, ruled with a strong arm but mysteriously died in 1843.

The next considerable extension of Egyptian rule occurred in 1840 when Ahmad Pasha Abu Adhan seized the region of Taka, the future Kassala Province, from the Hadendoa. The ports of Suakin and Massawa, leased to Egypt in 1846, were finally ceded

to the khedive Ismail (*see* ISMAIL PASHA) in 1865. Ismail sought to develop and expand his Sudanese possessions. In 1869 he commissioned Sir Samuel White Baker to annex the region between Gondokoro and the great lakes. Baker's mission, though heroically accomplished, was an expensive failure, and his successor in the Equatoria Province, Col. (afterward Maj. Gen.) Charles George Gordon (*q.v.*), withdrew the Egyptian garrisons from most of the area. The Egyptians extended their authority as far as the Somali coast and probably would have occupied Kismayu (Chisimaio) if Britain had not intervened. The final stage of Egyptian expansion was completed in 1874 with the conquest of Darfur. Ismail's attempts to gain territory from Ethiopia failed when two Egyptian invading armies operating from Massawa were defeated in 1875 and 1876.

Despite various experiments in decentralization by Mohammed Ali, Mohammed Said Pasha, and Ismail, the government was for most of the time based on Khartoum. The political structure devised for the Sudan followed the Egyptian model. A governor general and central government services were located at the capital. Each main territorial subdivision was ruled by a governor. The settled parts of each governorate were again divided into a number of districts, each under a district officer. Each tribe was administered by its own sheikh. During Ismail's rule technical departments responsible for steamers, posts, and telegraphs were added to the government services.

The Egyptian rule brought many changes to the Sudan. For the first time in its history the Egyptians imposed a single government over the whole country. Practices foreign to Sudanese religious traditions were introduced; the Sudanese Muslims followed the Maliki discipline, whereas the Egyptian law courts administered the Hanafite discipline which was official throughout the Ottoman Empire. At first the judges and the higher ulema (*'ulama'*), or Muslim scholars, were exclusively Egyptian, but as time went on the Sudanese took an increasing part in judicial work.

The forces which made the first penetration of the Sudan were composed of Turks, Albanians, and Arab irregulars. Climate and economy dictated the conscription of Negro soldiers captured in raids. By 1843 most of the troops in the Sudan were composed of Sudanese Negroes. Their officers were at first Turks; then selected Sudanese were given commissions until in 1872 a Negro, Adam Pasha al-Taqalawi, became acting governor general. In the higher civil administration there were two Sudanese provincial governors: Husayn Pasha Khalifa and Mohammed Rasikh Bey. The cultural influence of Egypt was confined to the small assimilated class in larger towns where, in the time of Ismail, primary schools were established on the Egyptian model. There was no large-scale immigration of Egyptian settlers, though there was much intermarriage with Sudanese in the garrison towns. The way of life of the mass of the Sudanese people was unaffected by the Egyptian presence.

**3. Mahdist Theocracy, 1881-98.**—On June 29, 1881, at Aba on the White Nile, Mohammed Ahmed ibn al-Sayyid 'Abdullah proclaimed himself as the expected Mahdi who had been divinely elected to restore Islam. His revolt was partly a protest against Egyptian misgovernment. The Egyptian administration was Ottoman in character; most of the senior public service posts were held by members of the europeanized, Turkish-speaking, Egyptian ruling class, whose way of life scandalized the austere Sudanese; and while there were influential Sudanese who were favourably disposed toward the regime by which they profited, the nomads were universally hostile. A more potent cause for discontent was the rough-handed attempt to suppress the slave trade.

The khedive Ismail's own role as a reformer, as well as the pressure upon him from the European powers, drove him to Draconian measures for its eradication. Islam tolerated slavery, but whereas in Egypt slavery had become an anachronism, the Sudanese economy was still based on it. When Ismail recruited European officers to carry out his policy more effectively, the Sudanese concluded that he had sold himself to the European unbelievers and that his government was undermining Islam. Another cause lay in the nature of Sudanese Islam itself, which found corporate expression in the Sufi religious orders, a religion of the heart, colourful and emotional. The Mahdist movement was not, as Egyptian and European writers of the time termed it, a revolt of dervishes against orthodox Sunni Islam. The Mahdi was no dervish and expressly forbade the use of the term by and for his followers. The movement was intended rather to restore primitive Islam and to cleanse it from innovation and superstition. The Mahdi's immediate enemy was the Egyptian government, which in his view had lapsed into unbelief.

The governor general at the time, Mohammed Ra'uf Pasha, an indecisive man, underestimated the strength of the movement. After massacring a small government force sent to arrest him, the Mahdi and his followers retired to the Nuba Mountains, where in December 1881 and May 1882 they annihilated two columns sent against them. In 1882-83 they won a series of spectacular victories over the Egyptian garrisons and the expeditions sent for their relief. Early in 1884 the Mahdist horde closed on Khartoum. On Jan. 26, 1885, the capital fell, and its redoubtable commander, Gordon, was killed. Four days later the Mahdi solemnly led the Friday prayers in the city mosque. Within the next few months the remaining Egyptian garrisons in the Sudan were evacuated or compelled to surrender, and the Anglo-Egyptian force, which had vainly attempted the relief of Khartoum in the winter of 1884-85, retired from Dongola. Only Wadi Halfa, Suakin, and the Equatoria Province remained in Egyptian hands.

The Mahdi died at Omdurman, which he had made his capital, on June 22, 1885, and the control of the Mahdist state fell to the Khalifa 'Abdullahi (*see* KHALIFA, THE).

**4. Anglo-Egyptian Condominium, 1899-1955.**—The Mahdist power was broken by an Anglo-Egyptian army commanded by Sir Herbert (afterward Lord) Kitchener. The occupation of the Nile Valley up to Khartoum was completed by the Battle of Omdurman on Sept. 2, 1898, but an extensive area of the country remained either unoccupied or in disputed ownership. However, disagreements with the French which had led to the Fashoda incident (*see* EGYPT: *History*) were settled by an Anglo-French declaration of March 21, 1899, whereby the French recognized the Nile-Congo watershed as the eastern limit of French interest, while the Belgians, who had occupied the country between the Nile-Congo watershed and Lado on the upper White Nile, agreed in 1906 that the Lado Enclave (*q.v.*) should revert to the Sudan on the death of King Leopold II (1909). By the Anglo-Egyptian condominium agreements of Jan. 19 and July 10, 1899, the northern border of

the Sudan was fixed at latitude 22° N with enclaves to include some villages north of Wadi Halfa and some Beja grazing grounds in the Red Sea hinterland. The Italians who had wrested Kassala from the Mahdists in 1894 handed it back to the Egyptian Army in 1897. On Nov. 24, 1899, Sir Francis R. Wingate's forces defeated and killed the Khalifa 'Abdullahi at Umm Diwaikarat, and in December the Egyptian Army reoccupied El Obeid. In 1898 a scion of the former royal house of Darfur, 'Ali Dinar, hastened to El Fasher (Al Fashir) and seized the throne. In 1900 the Khar-toum government accorded him recognition as a tributary sultan.

The condominium devised by Lord Cromer established the future form of the government. The British and Egyptian flags were to fly side by side. Supreme civil and military powers were to be vested in a governor general appointed by the khedive on the recommendation of the British government. The Sudan was to be excluded from the capitulatory regime and consular jurisdiction then in force in Egypt. The structure of the condominium was modeled closely on that of the former Egyptian regime. Under the governor general were governors of provinces, who in turn were assisted by inspectors and their Egyptian and Sudanese staffs. In a memorandum of 1899 Kitchener, who had been appointed governor general, laid down that the most important task of the governors and inspectors was to gain the confidence of the people by friendly dealing and close contact. Legal forms were to be strictly adhered to and Islam respected. Although slavery was not recognized, voluntary service by former slaves to their former masters was not to be interfered with, but cruelty to slaves was to be punished as a breach of law. Judicial officers prepared criminal and civil codes in 1899-1900. The Islamic law, confined as in Egypt to the realm of personal status, was administered by an Egyptian grand *qadi* (judge of the Islamic law), and a system of central and provincial courts. The first governors and inspectors were British officers of the Egyptian Army, but, as these were always liable to be recalled, a few graduates of British universities were appointed to form the nucleus of a civil service.

Kitchener was succeeded in December 1899 by Wingate, who was governor general until 1916 and who laid the foundations of the administration. The wars had reduced the country to poverty; in 1898 the revenue amounted to £35,000 against expenditure of £235,000. The annual deficit was met from the Egyptian treasury, and the Sudan was not solvent until 1913 when the budget was balanced.

Education under the Mahdist theocracy had been confined to the teaching of Arabic and religion in koranic schools. In 1898 Kitchener opened an appeal for funds to build Gordon Memorial College, which was opened as a primary school in 1902. By 1907 there were 6 primary and 20 elementary schools functioning, and the first government girls' school was opened at Rufa'ah. In 1905 a secondary section was added to Gordon College, which by 1913 provided a general secondary education with special courses for future judges of the Islamic law, engineers, and teachers. Sudanese communications expanded steadily. The Egyptian telegraph network had been destroyed during the Mahdist rule and had to be entirely reconstructed. The core of the railway system was the 3 ft. 6 in.-gauge military line built from Wadi Halfa to Khartoum North in 1897-99. An extension was laid to Sennar and El Obeid in 1909-11. The Red Sea railway was built from Atbara to Suakin in 1904-05 and extended to Port Sudan, where a new port was established. A steamers' department, based on a dockyard at Khartoum North, operated services on the principal navigable reaches of the two Niles and the Bahr el Ghazal (see *Transport and Communications*, below).

During World War I the Sudan enjoyed internal tranquillity and economic prosperity. Though Turkey was at war with Britain, the sultan's claim to the caliphate of Islam was not recognized in the Sudan. The Arab revolt which broke out in the Hejaz (Arabia) in 1916 found much sympathy in the Sudan which formed a base of supply for the Arab insurgents in the first phase of hostilities. In 1916 Sultan 'Ali Dinar of Darfur, who was already troubled by French encroachments on the buffer states on his western border, revoked his nominal allegiance to the Sudan government. A force commanded by Lieut. Col. (afterward Brig. Gen.)

P. J. V. Kelly routed the Fur Army near El Fasher on May 22. 'Ali Dinar fled to Jabal Marrah, where he was killed on Nov. 6. Darfur was brought within the Sudanese administrative system, but the western frontier with the French was not finally demarcated until 1924.

Experiments proved that the Egyptian long-staple cotton (which originated in the Sudan) could be profitably grown in the Gezira. The construction of a dam over the Blue Nile at Sennar, started in 1914, was not brought into use until 1926. The water thus impounded was used to irrigate a vast cotton plantation in the eastern Gezira, which attained about 1,000,000 ac. (405,000 ha.) in 1955 and provided the Sudan with its principal cash export crop and with a great addition to its grain acreage. The cotton plantation at Tokar in the Delta of Khor (Khawr) Barakah was reconditioned in 1922, and another plantation was established in the Gash Delta near Kassala, a project made possible by the completion of a railway from Hayya on the Red Sea line to Kassala, opened in 1924. A line from Kassala to Sennar, providing an alternative rail link with Port Sudan, was brought into operation in 1929. An international commission was set up in 1925 to report on irrigation works in the Sudan which could be undertaken without detriment to Egyptian rights. Its findings were incorporated in the Anglo-Egyptian Nile Waters Agreement of May 7, 1929. A water-storage dam for Egyptian use was built between 1934 and 1937 at Jabal Awliya', 25 mi. S of Khartoum.

*Nationalism and World War II.*—The first signs of a Sudanese nationalist movement in the modern sense appeared in May 1921 with the publication of a manifesto entitled *The Claims of the Sudanese Nation*. Its author was a junior officer of a Sudanese battalion of the Egyptian Army, 'Ali 'Abd al-Latif, who in 1924 founded the White Flag League. After his arrest and imprisonment in June 1924 cadets of the military school paraded the streets of Khartoum, and at Atbara the Egyptian Railway Battalion mutinied. On Nov. 19, Sir Lee Stack, governor general of the Sudan and sirdar of the Egyptian Army, was assassinated in Cairo. The resulting British ultimatum to the Egyptian government included a demand for the immediate withdrawal from the Sudan of all Egyptian officers and purely Egyptian units of the Egyptian Army. After disorders in Khartoum, where Sudanese rioters killed British, Egyptian, and Syrian patients in a hospital, the Egyptian withdrawal was carried out. The Sudanese units of the Egyptian Army were then embodied in a Sudan Defense Force with British and Sudanese officers under a commandant responsible to the governor general.

The negotiations which led to the Anglo-Egyptian Treaty of 1936 were closely followed by the educated minority in the Sudan, and the next stage of nationalist development was reached in 1938 with the formation of a Graduates' General Congress, a body drawn from school-educated Sudanese. Ismail el-Azhari became secretary to the congress in 1939 and its president in 1940. The Sudan was heavily involved in World War II. In 1940 the Sudan Defense Force took the strain of the Italian pressure on the frontier and in 1941 assisted in the rout of the Italian forces in Eritrea and Ethiopia. Sudanese troops also took part in the North African campaigns (1942-43).

The war years saw a further growth of national awareness. An advisory council, created in 1944, presaged further constitutional change. Municipal development was slow, and it was not until 1942 that the first town council with full control over its budget was installed, but since that date the number of municipal authorities has increased. An ordinance of 1951 increased the representative element in local government. The development of education was a powerful contributing factor to an awakening sense of nationhood. Newspapers and broadcasting popularized the conception of the Sudan as a national unit. Even the religious orders found themselves taking political paths; the Khatmiyah, under the leadership of al-Sayyid Sir 'Ali el-Mirghani, whose family was traditionally loyal to Egypt, adopted a position friendly to Egypt's claims in the Sudan, while the Ansar, the Mahdist confraternity under al-Sayyid Sir 'Abd al-Rahman, posthumous son of the Mahdi, championed eventual Sudanese nationhood unshackled by political connections with Egypt. After 1946 two main parties, re-

flecting these two divergent points of view, emerged. In 1947 Anglo-Egyptian negotiations broke down on the issue of the Sudan, and in July the Egyptian government referred the dispute to the UN Security Council but got no satisfaction. In the absence of a settlement the governor general in June 1948 announced a program of constitutional advance, including the creation of an executive council and a legislative assembly, which met in December. The preceding elections had returned the Umma Party, the political expression of neo-Mahdism, to power with the party secretary, Brig. 'Abdullah Khalil, as leader of the assembly. On Oct. 8, 1951, Egypt unilaterally abrogated the treaty of 1936 and proclaimed King Faruk I as king of Egypt and the Sudan, a pronouncement which made no serious impression upon Sudanese opinion.

The Egyptian *coup d'état* of July 1952 radically altered Sudanese-Egyptian relations. On Nov. 2, Gen. Mohammed Naguib, himself half-Sudanese, publicly recognized the Sudan's right to self-determination. On Feb. 12, 1953, Britain and Egypt signed an agreement by which the Sudan would attain self-government within three years. In the elections held late in the year the National Unionist Party won a victory, and Ismail el-Azhari was elected prime minister. Though he came to office on a political program favourable to Egypt, relations with Cairo worsened during 1955, and the prime minister complained of Egyptian interference in the internal affairs of the Sudan. By the end of 1954 almost all the British officials had handed over their duties to their Sudanese colleagues. A mutiny in the Equatorial Battalion of the army broke out in August 1955, accompanied by serious disturbances and loss of civilian lives. A commission of inquiry which issued its report on Oct. 19 advanced seven causes for the outbreak, among them fear in the non-Muslim south of the political domination of the Muslim north, the circulation of false rumours, and official maladroitness.

**5. Republic of the Sudan.**—On Jan. 1, 1956, the Sudan proclaimed its independence. The last governor general, Sir Knox Helm, resigned; British and Egyptian troops had already left the country. In spite of the formation (February 1956) of a national government headed by el-Azhari, the ministry fell on July 4 by the defection of ministers, loss of support in the assembly, and the intervention of al-Sayyid Sir 'Ali el-Mirghani, who became patron of the seceding party. 'Abdullah Khalil was elected prime minister of a coalition in which his own Umma Party was prominent.

A frontier incident arose in February 1958 between Egypt and the Sudan resulting from the disputed ownership of the two enclaves north of the 22nd parallel. The Sudan submitted the dispute to the UN Security Council, but the incident was closed by direct agreement between the disputants.

Elections held in March 1958 gave the victory to an alliance between the Umma and the People's Democratic parties, and 'Abdullah Khalil remained in office. There followed a period of political tension threatening the existence of the government, which was heavily attacked for its handling of the economic crisis. There were serious divisions in the cabinet. On Oct. 27 all political meetings in Khartoum, Omdurman, and Khartoum North were banned.

A military *coup d'état* was carried out bloodlessly on Nov. 17, 1958, when a group of army officers headed by Gen. Ibrahim 'Abboud took over the government, dismissed Parliament, dissolved all political parties, and suspended the transitional constitution. The officers who formed the supreme council of the revolutionary government soon began to exhibit the same lack of unity which had weakened the fallen ministry. A counterrevolution on March 4, 1959, by Brigadiers Abdur Rahim Shennan and Mohieddin Ahmed Abdullah, whose troops overawed Khartoum, forced the president to include them in the reconstituted Supreme Council. The two officers opposed alignment with the West and urged a closer identification of the Sudan with the Arab states. The Supreme Council did not achieve internal harmony, and on June 1 the two brigadiers, with other officers, were arrested on a charge of attempting once again to use troops to further their aims. The brigadiers and four others were found guilty and sentenced to death, but the sentences were commuted. A third attempt to overturn the re-

gime occurred on Nov. 10, 1959, when some officers, mostly from the Omdurman Infantry School, defied the government. Five of the officers were hanged and five imprisoned.

In spite of the stability which it imposed on the country and its international reputation for sound financial policy, the military government encountered increasing unpopularity. In October 1964 a fracas between police and Khartoum University students set off a train of disorders which culminated in the fall of the Supreme Council for the Armed Forces and the formation of a provisional government of civilians with Sirr al-Khatim Khalifa, a civil servant, as prime minister. Though Gen. 'Abboud was at first retained as titular president, widespread protests led to his resignation on Nov. 15. A purge of certain officers and officials of the former regime followed during the winter. On Feb. 23, 1965, Khalifa, who had resigned the premiership on Feb. 18, was recalled by the revived Council of Sovereignty (see *Administration and Social Conditions*, below) to head a coalition ministry. General elections, postponed in March, were finally held in April, resulting in the return of the two right-wing parties, the Umma followed by the National Unionists. These two parties supported a coalition cabinet with Mohammed Ahmad Mahgoub (Umma) as prime minister and Ismail el-Azhari (National Unionist and former prime minister) as president of the Council of Sovereignty.

**The Southern Provinces.**—In 1959 Christian mission schools were nationalized, and during 1962–64 foreign missionaries of all denominations were denied reentry to, and finally were expelled from, the southern Sudan. An extension of the teaching of Arabic was intended to further the linguistic and cultural assimilation of the pagan and Christian south with the Muslim and Arabic-speaking north. These intentions were frustrated by the outbreak in 1963 of an armed revolt in the southern provinces against the security forces which resulted in bloody reprisals, the breakdown of government over a wide area, and a serious threat of epidemics, a situation in which any hope of consultation with the southern electorate was impossible. The dissidents, with arms supplied by the Republic of the Congo and elsewhere and supported by Sudanese refugees in neighbouring states, were themselves divided in their political aspirations between independence and some form of federation with the north. The Khalifa government took steps toward reconciliation by giving two key cabinet posts to southerners and by holding a conference with representatives of the southern parties at Khartoum in March 1965. Northern sympathies, however, had been largely alienated after communal riots in the capital in late 1964. The Mahgoub government's resolve to restore order in the south led to further embitterment.

**Economic Progress.**—A Sudanese-Egyptian agreement signed in Cairo in 1959 superseded the Nile Waters Agreement of 1929 between Britain and Egypt. The Sudan consented to the building of the High Dam near Aswan (*q.v.*) by Egypt (United Arab Republic), while the latter agreed to compensate the Sudan government for the loss of land by Sudanese inhabitants as the result of the creation of a vast reservoir behind the dam. The Sudan was to be free to carry out its own projects, including a dam (completed in 1964) over the Atbara at Khashm al Qirbah to irrigate new land for the use of the Sudanese cultivators driven from the Nile Valley; a dam over the Blue Nile at Er Roseires (Ar Rusayris); and the extension to the central Gezira of the vast cotton plantation watered by the Sennar Dam. Sudanese communications developed spectacularly after 1945 with the extension of the railway system to Er Roseires in 1958, to Nyala in Darfur in 1959, and to Waw on the Bahr el Ghazal in 1962. A new state-owned Merchant Navy commissioned its first two seagoing ships in 1962. (R. L. HL.)

Sudan declared war on Israel when fighting broke out between Israel and Egypt in the Sinai peninsula on June 5, 1967. Sudanese troops were sent to the U.A.R. (X.)

## VI. ADMINISTRATION AND SOCIAL CONDITIONS

**1. Government.**—The Anglo-Egyptian condominium began in 1899 and ended on Dec. 31, 1955. It was terminated after a transitional period under the terms of the Anglo-Egyptian agree-

ment of February 1953. For nearly three years the new republic was governed by a Council of Ministers based upon a majority in the House of Representatives; there was also a Senate and the five-man commission which functioned as chief of state.

From November 1958 to November 1964 the supreme commander of the Sudan Army, Gen. Ibrahim 'Abboud, was head of state and head of the government; but after unrest and disturbances in the autumn of 1964, a civilian government was formed and the central and provincial councils created by the military government were abolished. In December, in accordance with the provisional constitution of 1956, the five-man commission (Council of Sovereignty) was revived to perform the function of the head of state, and in April 1965 a general election was held in the north. The Umma party won 75 seats, the National Unionist 54, the Beja Tribal Association 10, the Islamic Front 5, the People's Democratic 3, and the Communists 11. Independents won 15 seats. In December 1965 a law was passed to prevent Communists from sitting in the House. A cabinet of nine ministers (three representing the south) was formed in June 1965 (see *History*, above).

**2. Administration.**—The Sudan is divided into nine provinces which are related to the two main lines of communication: the Nile River and the east-west "pilgrim" route from West Africa to Suakin on the Red Sea. The provinces were formerly divided into districts, at first administered directly by district commissioners; but devolution to local authorities began in 1918 and passed through further stages in 1937 and 1954. Provinces and districts have powers of taxation, and responsibilities in the spheres of health, education, and veterinary services. Governors of provinces are responsible to the Ministry of the Interior.

Khartoum is the capital of the republic and in 1956 had a population of 93,103; (1964 est.) 135,000.

*Provinces of the Republic of Sudan*

Province	Capital	Area (sq.mi.*)	Population (1963 est.)
Bahr el Ghazal.	Wau	82,529	1,227,050
Blue Nile	Wad Medani	54,879	2,542,650
Darfur	El Fasher	191,648	1,631,850
Equatoria	Juba	76,495	1,113,200
Kassala	Kassala	131,527	1,163,800
Khartoum	Khartoum	8,097	619,850
Kordofan	El Obeid	146,929	2,175,800
Northern	Ed Damer	184,198	1,075,250
Upper Nile	Malakal	91,189	1,100,550

\*1 sq.mi. = 2.59 sq.km.

**3. Living Conditions.**—According to the 1956 census the labour force comprised about 3,800,000 (37% of the total population), the great majority of whom were engaged in farming and animal husbandry. In industry, commerce, and public administration there is legislation to cover employment exchanges, conditions of employment in factories and in domestic service, and workmen's compensation. There are employment exchanges in the largest towns of the northeastern Sudan. Trade unions have been recognized since 1948, and negotiate with employers (including the government) on wages and working conditions. Under an amending ordinance of 1960, provision is made for closer control by the labour commissioner. Another ordinance of 1960 prescribed that disputes should be compulsorily arbitrated when negotiation and conciliation fail. Under legislation applying to cooperative societies, many such bodies have been registered, of which about 150 are agricultural and more than 100 are for marketing and credit.

Towns are planned so that there are separate first-, second-, and third-class residential areas, as well as commercial and industrial zones. Buildings must be erected in conformity with regulations governing materials to be used, number of stories, etc. Outside the limits of towns and separated from them by open land are *deims* (*dayms*) where unregulated houses, i.e., shacks and native huts, may be erected. In rural areas generally, where the population is sedentary, housing conforms to tribal custom and usually comprises square flat-roofed, mud-brick dwellings (in the north) or circular grass huts with conical thatched roofs. The nomads live in tents.

**4. Public Health.**—Early in the 20th century the Sudan was reputed to be very unhealthy, and epidemics of sleeping sickness, cerebrospinal meningitis, and yellow fever were frequent. The progress of medical and sanitary services under the Sudan Medical Service (later the Ministry of Health), supplemented in many places by missionary institutions, has reduced mortality. By 1965 there were about 70 government hospitals of different grades, located in all important centres. Rural areas were served by more than 1,000 dispensaries and dressing stations under medical assistants. There are doctors in private practice in larger towns. There is also a rural midwife service, provided by more than 1,400 women trained in government schools who practise from their homes.

**5. Justice.**—Civil justice is administered through the High Court of Justice in Khartoum, province courts, and lower courts. There is a body of civil law; but where there is no special enactment, cases are decided according to "justice, equity, and good conscience." The criminal code is based upon the Indian penal code and is dispensed in major, minor, and magistrate's courts. Complementary to the state courts, there are also local courts, constituted under the Native Courts Ordinance (1932) and the Chiefs' Courts Ordinance (1931), which try a substantial proportion of both civil and criminal cases. Muslims in the north are subject to the Shari'ah, or religious law of Islam, in questions of inheritance, marriage, divorce, family relationship, and charitable trusts.

**6. Education.**—In the Muslim areas of the north, boys have long been instructed in religious subjects according to traditional methods. During the condominium, and as the outcome of an appeal by Kitchener in 1898, modern primary education was begun in the northern Sudan, and secondary education commenced in 1913 (see *History*, above). Post-secondary schools in arts and science, agriculture, veterinary science, engineering, and law were established between 1938 and 1941. In 1947 these schools were brought together within Gordon Memorial College, which was linked in special relationship with the University of London until 1959. Education in medicine began in 1923, at the foundation of the Kitchener School of Medicine. In 1951 this school was united with Gordon Memorial College in the University College of Khartoum (which in 1956 became the University of Khartoum).

In the south, missionaries were responsible for education, with the consent and support of the government, until 1957; then the government assumed direct control, as a result of which Arabic was given greater prominence in the curriculum.

The census of 1955–56 disclosed that over 85% of the total population aged five years and above had never attended any school. In the mid-1960s there were about 3,100 government schools with 520,000 pupils, and more than 170 nongovernment schools, of all grades, with about 46,500 pupils. There were also 37 intermediate and secondary religious (Muslim) schools, attended by over 6,300 pupils. The *Maahad Ilmi* in the mosque at Omdurman, attended by pupils from Muslim areas, provides theological education and trains the religious leaders (*ulemas*) and lawyers (*qadis*). The principal centre for the training of intermediate school teachers is the Institute of Education at Bakht at Ruda, near Ed Dueim, for men, and at Omdurman for women.

The University of Khartoum has faculties of agriculture, arts, science, economics, engineering, law, medicine, and veterinary science. English is the medium of instruction in the university and the secondary schools, but it is being replaced by Arabic in the secondary schools. A branch of Cairo University in Khartoum provides facilities for evening classes in arts, law, and commerce. The classes are conducted in Arabic. The Khartoum Technical Institute was founded in 1950.

**7. Defense.**—The Sudan Army had its origin in the Sudan Defense Force, founded in 1925. The total rifle strength in 1955, when the British officers left, was between 4,000 and 5,000, and it remained at about 5,000. There are also technical corps based at Omdurman and Khartoum, and artillery is based on Atbara. Some light aircraft have been acquired, and there is a small naval force on the Red Sea composed mainly of patrol boats.

## VII. THE ECONOMY

The Sudan's economy depends almost wholly upon agricultural and pastoral products. Minerals and sources of power are lacking, and industrial development was in its infancy in the mid-1960s. Commercial development has been mainly in the north and east.

**1. Agriculture and Pastoral Production.**—In the west and south both crops and livestock are produced mainly for subsistence, and little is sold. In the north and east surpluses are available and are moved to towns or exported. The only capitalized agricultural production, applying modern technical knowledge, is from the irrigated areas close to the Nile in the northeast and some areas under rain cultivation near Gedaref.

The chief food crops are the common millet (*durra*) and bulrush millet (*dukhni*). The latter flourishes on the sands of the dunes. Millet cultivation extends across the country in an east-west zone—the central rain lands—between latitudes  $10\frac{1}{2}^{\circ}$  N and  $14^{\circ}$  N, but is also grown by Nilotic peoples near their permanent villages. In the far south, finger millet (*eleusine*) and maize (corn) are preferred. The area under *durra* and *dukhni* has increased in the northeastern Sudan concomitantly with the population in the 20th century; this has been true especially in the clay plain (since World War II) as a result of the provision of new roads and perennial water supplies from *hawafir* or excavated reservoirs. Near Gedaref, the introduction of mechanized production has proved profitable. *Durra* also enters into the rotation of crops in irrigated areas. Yields of millets fluctuate mainly according to rainfall, and in years of poor harvests the supplies to towns and deficiency regions cause the government anxiety; but the cultivator makes use of underground storage in pits and in lean years draws upon his reserves. In good years some grain is exported. Wheat is grown as a winter crop along the Nile in Northern Province.

Sesame and peanuts are also important; both are normally exported. A bean known as *lubia affin* (*Dolichos lablab*), a clover (*berseem higazi*), and alfalfa are grown for fodder on irrigated land. Tobacco is widely grown in Darfur and is the only crop which can justify the cost of transport from that remote part of the country. Medium- and low-quality dates are a traditional product of the Nile Valley north of Shendi and find a market throughout the northern Sudan.

Citrus fruits, especially limes and grapefruit, are produced at Kassala, in irrigated gardens along the Nile and near some towns in both north and south. Market gardening is also established in some areas but does not produce an adequate supply of fresh vegetables. In the southern Sudan tobacco, coffee, sugar, rice, and the oil palm are all cultivated experimentally, but commercial output has been negligible.

Cotton is the major cash crop and, since the completion of the Sennar Dam in 1925, has become the mainstay of the Sudan's economy. Until about 1960 the long-staple Sakellarides varieties were dominant because of the higher prices they commanded in the world market. But lessened demand for these types of cotton has prompted increase in production of medium- and short-staple varieties and the diversification of cash crops generally. Long-staple production is supplemented with short-staple (chiefly American) varieties in areas of adequate rainfall, especially in the vicinity of the Nuba Mountains. New pump projects and

the Manaquil extension to the Gezira project have greatly increased the area under cotton. In the mid-1960s this exceeded 1,000,000 feddans (1 feddan = 1.038 ac.), of which about 200,000 were un-irrigated, mainly in Kordofan and Kassala provinces. The production of long-staple seed cotton, almost wholly from irrigated land, amounted to about 410,000 metric tons and of short-staple (rain grown) seed cotton to about 37,500 metric tons. The Sudan Gezira Board (established in 1950) controls most of the country's cotton production. A large extension to irrigated farming (the Kenana scheme) will be possible when the new Er Roseires Dam on the Blue Nile is completed.

**Livestock.**—Pastoral activities extend throughout the country, except on the ironstone plateau of the southwest, which is infested by the tsetse fly, and on the desert of the north and northwest. There are about 2,000,000 camels, owned by Beja, Arab, and nomadic tribes of the north and west, which graze over the desert margin scrub. About 9,000,000 cattle are bred mainly in the central rain lands, especially by the Baggara tribes of southwest Kordofan and southern Darfur. Cattle also form the chief wealth of the Nilotic tribes. There are an estimated 8,600,000 sheep and 6,800,000 goats, associated both with camel and cattle rearing in the north. Goats are also numerous in the towns as milk suppliers. Camels and small numbers of cattle are exported to Egypt, and sheep to Saudi Arabia; there is also sale for slaughter to towns. A corned-beef factory established at Kosti in 1950 was forced to close for lack of regular and adequate supply of animals despite the improvement of drove roads from the west and the possibility of transporting animals by air. Since 1945 the preparation and export of hides has been encouraged, with some success.

The growth of population and the settlement in new areas during the condominium, together with control of animal diseases by veterinary services, have greatly increased the use of cultivable land and natural grazing. In some areas land is losing its fertility, and the best fodder plants are disappearing. The provision of new water supplies (wells and *hawafir*) has been the chief conservation measure, rendering new areas of pasture and cultivable land available for use. Further methods of control are desirable, and have been under study by the land use department.

**Fisheries.**—The Nile system, and especially the White Nile above Kosti and the Bahr el Jebel, is an important source of fish, particularly Nile perch, for riverine peoples. Small quantities are sold in the towns, and a little is dried and salted.

**2. Forestry.**—The Sudan is one of the world's chief suppliers of gum arabic, chiefly *hashab* gum, which is collected from *Acacia senegal* in the central rain land zone from Darfur to Kassala; it is bought by exporting companies at government auctions. Timber is produced mainly in the south, apart from the dense hardwood known as *sunt* (*Acacia nilotica*), exploited in the Blue Nile and Dinder (Dindar) valleys. There are sawmills near Wau, Loka, and Katire, producing mahogany and other hard and soft timbers. The forests are the local sources of firewood and charcoal, and cutting is supervised; but severe inroads have been made into the more meagre woodlands of northern Sudan. The growing use of oil fuels is proving to be an ameliorative.

**3. Minerals.**—No large mineral deposits have been discovered, but gold, iron ore, manganese, limestone, mica, and chromite are exploited on a small scale. Salters at Port Sudan supply unrefined salt for the country's needs and for export.

**4. Industry and Power.**—Oil milling and soap making are established in some northern towns; Khartoum and Port Sudan have factories of moderate size. There is a cement works at Atbara. Steel and aluminum are fabricated into utensils in Khartoum and Wad Medani. A modern brewery operates in Khartoum North, and there are two distilleries in the Three Towns. Factories for shoes, paints, glass, knitwear, sweets, and cigarettes also operate in Khartoum. A cotton-spinning and weaving mill was opened at Nzara, near Yambio, Equatoria, in 1951 as part of a plan for social emergence based upon regional self-sufficiency. Khartoum North and Omdurman each have a cotton-spinning and weaving mill. There are motor-maintenance workshops and tire-retreading works in Khartoum and elsewhere. The railway workshops at Atbara are the largest industrial unit in the country. River steamers and barges are repaired in the dockyards at Khartoum North and Kosti. Local craftsmen make leather goods, clothes, pottery, furniture, household utensils, and implements in the bazaars of northern towns. Small electric-power stations serve domestic and industrial consumers in larger towns. A power station on the Sennar Dam has the potential to supply Gezira and Khartoum with 15,000 kw. of electricity.

**5. Trade and Finance.**—The principal exports of the Sudan are cotton and cottonseed, peanuts, gum arabic, and sesame. The principal imports are textiles, petroleum products, machinery, refined sugar, base metals and manufactures, and vehicles. In the mid-1960s the chief receiving countries were the U.K., India, Italy, Federal Republic of Germany, U.A.R., and U.S.S.R. Chief sources of supply were the U.K., India, U.A.R., Japan, Federal Republic of Germany, and the U.S.

Indirect sources of revenue include import duties, royalties on exported products, and the profits of trading concerns such as the cotton projects and the sugar monopoly. Direct taxes include those on dates, animals, land, crops, houses, and income. There is also a poll tax, and tribute is levied upon certain tribes. The monetary unit is the Sudanese pound (£S), divided into 100 piastres and 1,000 milliemmes, which is equal to £1 0s. 6d. sterling.

In the mid-1960s revenue exceeded £S70,000,000 and ordinary expenditure was about £S57,000,000. From 1945 additional development budgets financed five-year plans, and annual development budgets provided for projects, including the dam at Er Roseires, the Khashm al Qirbah (Atbara River) scheme, the Manaqil extension to the Gezira scheme, the Sennar hydroelectric scheme, and the Guneid (Junayd) sugar factory. A ten-year development plan for 1961–71 provided £S287,300,000 for social and economic development.

The external public debt stood at about £S3,000,000 at the beginning of the 1960s. Loans or credits have been obtained from the International Bank, International Monetary Fund, the United Kingdom, the Federal Republic of Germany, Yugoslavia, and Kuwait (for railway development). A credit under the American aid agreement (1952–59) was principally for establishing a textile industry in the northern Sudan and for railway extension and im-

provements. Under an agreement with the U.S.S.R. (1961) financial and technical aid was provided for the construction of food-processing factories.

**Banking.**—Until 1960 banking was provided by foreign concerns, led by Barclays Bank D.C.O. (Dominion, Colonial, and Overseas) and the National Bank of Egypt. The latter was acquired by the state, renamed the Bank of Sudan, and reorganized as the central bank for the country. The state-owned Agricultural Bank of Sudan provides agricultural credit. Foreign banks, apart from Barclays, include the Arab, Misr, Ottoman, Crédit Lyonnais, and the State Bank of Ethiopia. The Industrial Bank of Sudan was officially inaugurated in 1962.

**6. Transport and Communications.**—Communications in the north are provided by the Sudan railways. The line from Wadi Halfa to Khartoum was built in 1897–99; the Atbara-Port Sudan branch was opened in 1904–06; and the main line from Khartoum (via Sennar and Kosti) to El Obeid was extended in 1906–11. Except for the Kassala-Haiyya (Haiya) loop, completed in 1929, railway building ceased until 1950. A branch from Sennar to Er Roseires was completed in 1956, and a westward extension from Ar Rahad via Abu Zabad and Ed Da'ein (Ad Du'ayn) to Nyala in 1959. A branch line from Babanusah (on the latter extension) southwestward across the Bahr al 'Arab to Wau was completed in 1962. This railway system facilitates the economic advance of the north by providing the means for bulk movement of cotton, oilseeds, hides, and gum arabic, as well as the distribution of imported goods. The extensions westward are intended to stimulate commerce in Darfur and Bahr el Ghazal.

In the south the White Nile and the Bahr el Jebel, between Kosti and Juba, and the Bahr el Ghazal as far as Meshra' er Req (Mashra' ar Raqq) are navigable throughout the year and have regular passenger and freight services. The Jur River is navigable from its confluence with the Bahr el Ghazal to Wau from July to October, and the Sobat from May till December. From ports on these rivers an all-weather road system serves the provinces of Bahr el Ghazal and Equatoria (on the ironstone plateau); but Up- per Nile, on the clay plain, possesses only dry-weather tracks, and portage is still necessary away from the rivers except between December and May.

There are no improved roads in the northern Sudan; but motorable tracks (with locally improved stretches to ensure continuity over soft, rocky, or marshy ground) are used by trucks and estate and heavier cars, except after heavy rainfall between July and September. The soft sand of the dunes greatly impedes motor transport in central and southwestern Kordofan and in eastern Darfur.

Khartoum is an important stopping place on the main Cairo-Cape Town air route, with feeder services to the east (Eritrea and Aden) and to the west. The government-owned Sudan Airways operates internal air services between the Three Towns and most provincial capitals and external services to Egypt, Aden, Jidda, Jordan, Eritrea, Nairobi, Lebanon, Athens, Frankfurt, Rome, and London.

**Telecommunications.**—The telegraph system serves most settled parts of the country. A telephone service exists in the north and east. In the south, and in Darfur, radio transmission is employed instead of land lines. Communications abroad are by means of cable, land line, and radio (telegraphy and telephony). The government-controlled Sudan Broadcasting Service at Omdurman broadcasts in Arabic and English.

**SUDANIC LANGUAGES.** The term Sudanic has been used to designate many African languages spoken from Ethiopia in the east to Nigeria in the west. Totally unrelated languages have been included in the various groupings listed as Sudanic, either on geographic or other nonlinguistic grounds. A more satisfactory classification is that of Joseph H. Greenberg, which is based upon strictly linguistic relationships.

Chari-Nile (or Macro-Sudanic) includes Central Sudanic, Eastern Sudanic, Berta, and Kunama. Even this broad grouping is tentative. Central Sudanic includes the Moru-Madi group (in the Sudan, northeast Republic of the Congo, and northwest Uganda) and the Bongo-Baka-Bagirmi group (largely in Cameroon, Chad, and the Central African Republic but extending east into the Sudan). Eastern Sudanic (on the upper Nile, largely in the Sudan, Uganda, and Kenya but extending into Tanganyika) has seven branches: Nubian, Beir-Didinga, Barea, Tabi, Merarit, Dagu, and Southern. Old Nubian is known from medieval records ranging from the 8th to the 11th centuries. The Southern branch includes (1) Nilotic proper or West Nilotic, including Shilluk, Nuer, Dinka, Lango, and Acholi; (2) East Nilotic, including Bari, Masai, Turkana, and Lotuko; and (3) South Nilotic (Nandi-Suk). See also AFRICAN LANGUAGES.

**SUDBURY, SIMON OF** (d. 1381), archbishop of Canterbury (1375-81), the most distinguished victim of the peasants' revolt, was the son of Nigel Thebaud (Theobald or Tybald) of Sudbury, Suffolk. His appointment to the See of London by Pope Innocent VI in 1361 was a reward for service at the papal curia; he was an auditor of the Rota for 12 years and in 1359 the pope sent him to England in an attempt to persuade Edward III to open peace negotiations with France. Capable and efficient, he was a conscientious and popular bishop. Translated to Canterbury in May 1375, he crowned Richard II on July 16, 1377; as primate, he avoided conflict with the state but showed firmness in his dealings with his suffragans. John Wycliffe appeared before him in

February 1378 to answer charges of heresy. He became chancellor in January 1380. In 1381 the Kentish rebels held Sudbury and the lord treasurer, Sir Robert Hales, responsible for the hated poll tax. When the Tower of London was surrendered to the insurgents on June 14, Sudbury and others were beheaded on Tower Hill.

**BIBLIOGRAPHY.**—*Registrum Simonis de Sudbiriā, 1362-75*, ed. by R. C. Fowler (1927-38); W. L. Warren, "A Reappraisal of Simon Sudbury," *The Journal of Ecclesiastical History*, vol. x, no. 2. (1959). (T. B. P.)

**SUDBURY**, a city in southeastern Ontario, Can., 264 mi. (425 km.) NW of Toronto and the seat of Sudbury District. Pop. (1961) 80,120. The chief retail and wholesale centre for the area known as Northern Ontario, Sudbury began with the arbitrary location of a station on the new Canadian Pacific Railway. Copper-bearing ores containing large quantities of nickel were unearthed in 1883 during construction of the railway, but it was not until the metallurgy of copper-nickel separation was solved that development started and the major growth of the city began.

By the end of 1945 over \$1,000,000,000 worth of nickel and \$500,000,000 worth of copper had been produced. In the 1960s Sudbury still produced about 50% of the world's nickel and almost all of Ontario's copper. The huge concentrator and smelter of the International Nickel Company is at Copper Cliff, 4 mi. W of Sudbury. Falconbridge Nickel Mines Ltd. operates a nickel-copper mine, concentrator, and smelter at Falconbridge, about 12 mi. NE of Sudbury. More than three-quarters of those gainfully employed work in mining and metallurgy, earning a higher average wage than the workers of any other Canadian city.

Sudbury was incorporated as a town in 1893 and as a city in 1930. Modern Sudbury is a well-built city with more than 20 mi. of paved streets. It has an extensive business section with many stores, hotels, and large office buildings, as well as many fine churches and schools.

The Laurentian University of Sudbury, a bilingual Roman Catholic university, was established in 1957. (F. A. CK.)

**SUDBURY**, a municipal borough of West Suffolk, Eng., lies on the River Stour 22 mi. (35 km.) W of Ipswich by road. Pop. (1961) 6,642. One of the medieval wool towns, it has many beautiful half-timbered buildings and three Perpendicular churches: All Saints, with a fine oaken pulpit dating from 1490; St. Peter's, with a carved nave roof; and St. Gregory's, once collegiate, which contains a rich, spire-shaped font cover of wood, gilded and painted. The grammar school was founded by William Wood in 1491 (rebuilt 1857). The artist Thomas Gainsborough (1727-88) was born there in a house that is now an art centre. An earlier native was Simon of Sudbury, or Simon Tybald, archbishop of Canterbury, who was murdered in Wat Tyler's rebellion and whose head is preserved in St. Gregory's. Before the Conquest the borough was owned by the mother of Morcar, earl of Northumbria, from whom it was taken by William I. It probably then passed to Robert, earl of Gloucester, and in the 1270s Gilbert de Clare, earl of Gloucester, gave the burgesses their first charter confirming their ancient liberties. Sudbury was incorporated in 1554.

**SUDERMANN, HERMANN** (1857-1928), one of the leading writers of the German Naturalist movement, was born at Matziken, East Prussia, on Sept. 30, 1857, of a Mennonite family. Though first apprenticed to a chemist, he was eventually able to attend Königsberg University. After a short period as tutor in Berlin he worked as a journalist, then turned to novel writing. *Frau Sorge* (1887; English translation, *Dame Care*, 1891), a keenly observed description of the growing up of a sensitive youth, and *Der Katzensteg* (1880; Eng. trans., *Regine*, 1894) are the best known of his early novels. He won fame, however, with his plays. *Ehre* (1890; Eng. trans., *What Money Cannot Buy*, 1906), first performed in Berlin on Nov. 27, 1889, only a month after Gerhart Hauptmann's *Vor Sonnenaufgang*, was, like Hauptmann's play, a milestone in the Naturalist movement (see HAUPTMANN, GERHART), although to later criticism it seems a rather trite and slick treatment of class conflicts in Berlin. *Heimat* (1893; Eng. trans., *Magda*, 1896) carried his fame throughout the world and provided the favourite role for many prominent actresses. Influ-

enced by Ibsen, Sudermann sought to champion the equality of women, but the play is marred by a sickly sentimentality. His plays, notably *Das Glück im Winkel* (1896; Eng. trans., *The Vale of Content*, 1915), *Morituri* (1896; Eng. trans., 1897), *Es lebe das Leben!* (1902; Eng. trans., *The Joy of Living*, 1902), *Der gute Ruf* (1913; Eng. trans., *A Good Reputation*, 1915), were almost all successful on the stage of his time, for Sudermann's dramatic construction is skilful, his dialogue convincing, and his language simple; but when he seeks to depict passion, he often becomes sentimental, and his criticism of contemporary society—a recurrent motif—is superficial. Consequently, his plays are seldom staged today. Among his later prose writings, *Litauische Geschichten* (1917), a collection of stories, is powerful because he knows how to build up tension and describe the life of simple people convincingly. *Das Bilderbuch meiner Jugend* (1922; Eng. trans., *Book of My Youth*, 1923) is a vivid account of his early years in East Prussia. He died at Berlin-Grunewald on Nov. 21, 1928.

**BIBLIOGRAPHY.**—*Dramatische Werke*, 6 vol. (1923); *Romane und Novellen*, 6 vol. (1919). See also H. Schoen, H. Sudermann, Poète dramatique et romancier (1904); I. Leux, H. Sudermann (1931); T. Duglor, H. Sudermann, ein Dichter an der Grenzscheide zweier Welten (1958).

**SUE, EUGÈNE** (MARIE-JOSEPH SUE) (1804–1857), French novelist and a leading exponent of the *roman-feuilleton* ("news-paper serial"), was born in Paris on Jan. 26, 1804. His early experiences as a naval surgeon prompted several highly coloured sea stories; (e.g., *Plik et Plok*, 1831). He also wrote a number of historical novels.

Having inherited a fortune from his father, Sue became a well-known dandy. His carriage and horses, pack of beagles (a present from his friend Count d'Orsay), and displays of luxury made him the talk of Paris. He was one of the first members of the French Jockey Club (1834). He depicted contemporary "high life" in *Arthur* (1838) and *Mathilde* (1841). The latter showed Socialist tendencies, and Sue turned in this direction in *Les Mystères de Paris* (1842–43), which influenced Hugo's *Les Misérables*, and *Le Juif errant* (1844–45). Published in installments, these long but exciting novels vastly increased the circulation of the newspapers in which they appeared. His later works were less successful.

After participating in the 1848 Revolution, Sue was elected Socialist deputy for the Seine in 1850. He opposed Louis Napoleon's *coup d'état* in 1851, went into voluntary exile at Annecy, and remained there until his death on Aug. 3, 1857.

**BIBLIOGRAPHY.**—N. Atkinson, E. Sue et le roman-feuilleton (1929); J. Boulenger, Sous Louis-Philippe: les Dandys, new ed. (1932); J.-L. Bory, E. Sue. Le roi du roman populaire (1962). (S. C. Gd.)

**SUEBI** (Lat. SUEBI, SUEVI; Span. SUEVOS; Eng. SUEVES), a group of Germanic peoples (*q.v.*), including the Marcomanni and Quadi, Hermunduri, Semnones, and Langobardi (Lombards). In the late 1st century A.D. most of these tribes lived around the Elbe River, but some of them had already migrated from this area. Several Suebic tribes have their own separate history (see MARCOMANNI; LOMBARDS). Some Suebi were among the Alamanni (*q.v.*) and some gave their name to Swabia (*q.v.*). This article deals with the Suebic kingdom in Spain.

Dislodged by the Huns, some Suebi, together with two hordes of Vandals and the Alani, reached Mainz in 406, crossed the Rhine, and in 409 entered Spain. The Suebi settled mainly in the northwest (Galicia), their capital being Bracara Augusta (Braga, Port.). Their expansion was hindered by the campaigns of the Visigothic king Wallia in Spain (416–418) and the defeat of a Suebic army by the Vandals near Augusta Emerita (Mérida) in 429; but by 447, under their king Rechila, the Suebi had spread over Lusitania and Baetica. The Suebi entered Spain as pagans, and as late as the 6th century they retained several pagan superstitions. Their king Rechiar, however, came to the throne as a Catholic in 448. He attacked the Romans in Tarracensis but was defeated by the Visigoths under Theodoric II in 456.

This was described by the contemporary Hydatius, bishop of Aquae Flaviae (Chaves), in his *Chronicon*, as the end of the Suebic kingdom, but remnants of the Suebi survived under Maldras (456–

460) and rival kings. Remismund, who became sole king of the Suebi in 464, converted his people to Arianism during a temporary *rapprochement* with the Visigothic king. For the 90 years following 468 (when Hydatius' *Chronicon* ends) this history of the Suebi is obscure. King Theodimir (558–570) was converted to Catholicism by St. Martin, bishop of Braga. The reigns of Theodimir's two successors were disturbed, and c. 585 the kingdom was annexed to the Visigothic state.

See L. Schmidt, *Geschichte der deutschen Stämme: die Westgermanen*, 2nd ed. (1938–40); R. Menéndez Pidal (ed.), *Historia de España*, vol. iii, esp. part 1, ch. 2–3 (1940).

**SUESS, EDUARD** (1831–1914), Austrian geologist who, among his contributions to the theory of continental origins, postulated the existence of Gondwanaland (*q.v.*), was born at London on Aug. 20, 1831. He was educated at the universities of Prague and Vienna, specializing in invertebrate paleontology. In 1852 he became assistant in the Hofmuseum, Vienna, and in 1857 extraordinary professor of geology at the University of Vienna, becoming ordinary (or full) professor in 1867, a position he held until 1901.

While connected with the Hofmuseum, Suess published papers on the anatomy and classification of brachiopods, established the classification of ammonites, and described fossils belonging to several other groups.

After 1857 he turned to geology proper. In 1875 he published a small book on the origin of the Alps, in which he denied vertical uplift of mountains and continents, limited the role of vulcanism in mountain building, and declared that the Alps and related mountains had been formed by thrusting movements that crumpled and broke outer portions of the earth's crust. He also emphasized the existence of unyielding continental areas composed of very old mountain masses, now generally called shields.

His major work, *Das Antlitz der Erde*, published between 1885 and 1907, achieved great influence and was translated into Italian and French, and into English as *The Face of the Earth*. In it he expounded his interpretation of the earth's surface in terms of ancient changes in continents and seas. He also dealt with fluctuations of ancient seas, the rise of magmas, and other subjects related to his main thesis.

Suess became a member of the *Landtag* of Lower Austria in 1869, and in 1873 entered the lower house of the *Reichsrath*, where for more than 30 years he was Liberal deputy from Vienna. He died at Vienna on April 26, 1914. (M. A. F.; C. L. Fe.)

**SUETONIUS TRANQUILLUS, GAIUS** (b. c. A.D. 70, d. after A.D. 122), Roman biographer and antiquarian, is best known for his *De vita Caesarum* (*Lives of the Caesars*). Probably born in Rome, he was of equestrian family, a friend and protégé of the younger Pliny. He seems to have toyed with the law as a career but abandoned it; and having secured through his friend a military tribunate, he relinquished that also. It is possible, though not certain, that he accompanied Pliny on his mission to Bithynia (c. 110–113). After Pliny's death Suetonius found another patron, Septicius Clarus (to whom Pliny had dedicated his letters, and to whom Suetonius himself was later to dedicate the *De vita Caesarum*); upon the accession of Hadrian, Septicius became praetorian prefect, and, either then or a little before, Suetonius entered the imperial service. He held, probably simultaneously, the posts of *studii* and *bibliothecis*, controlling the Roman libraries, keeping archives and advising the emperor on cultural matters. In 121 Hadrian began his first grand tour of the empire, and probably at this time Suetonius was promoted to be *ab epistulis*, secretary of the imperial correspondence, in which capacity he traveled (along with his patron) in the emperor's suite. Both men were dismissed for neglect of court formality; the incident is recorded in the context of Hadrian's visit to Britain in 121 but may have taken place somewhat later. Presumably Suetonius devoted himself thenceforward to literary pursuits. The date of his death is unknown.

**Works.**—A list of writings of Suetonius is given in the *Suetonius Lexicon* (*q.v.*). Most of them were antiquarian; their titles indicate that they dealt with Greek pastimes, the history of Roman spectacles and shows, the Roman year, critical signs in books, the

terminology of clothing, oaths and imprecations and their origin, Roman customs and a defense of Cicero's *De republica* (probably of its style, not its politics). Other sources refer to similar works on famous courtesans, physical defects, the growth of the civil service, and on kings. An encyclopaedia like Pliny's *Natural History*, called *Prata* ("Meadows"), was attributed to him and often quoted in late antiquity; some of the works mentioned above may have been subsections of this.

However, Suetonius' main works were biographical: the *De vita Caesarum* and the *De viris illustribus*. The latter was a collection of short biographies of celebrated literary figures of Rome, divided into books on poets, orators, historians, teachers (*grammatici* and *rhetoires*) and perhaps philosophers. There survive the whole of the *De grammaticis* and the preface and first five lives of the *De rhetoribus*; in addition, the lives attached to manuscripts of several famous poets derive from Suetonius' book, especially those of Horace and Lucan. The life of Terence that begins Aelius Donatus' commentary on Terence comes from the same source, and so do the facts (but not the padding) in Donatus' life of Virgil. Since, in addition, the notices about writers inserted by St. Jerome in his Latin version of Eusebius' chronicle come from Suetonius, it is fair to say that almost all of what little is known about the lives of Rome's eminent authors is owed to him.

*Lives of the Caesars.*—Nevertheless, it is for the *Lives of the Caesars*, from Julius Caesar to Domitian, that Suetonius is famous. Upon them (along with the works of Tacitus) is largely based that vivid picture of Roman society and its leaders, morally and politically decadent, which dominated historical thought until modern times when the discovery of nonliterary sources of evidence did something to modify it. Moreover, under the influence of the *Lives*, much of later Roman historical writing was directed, to its detriment, into the biographical channel. They are organized not chronologically but by topics (the family background of the emperor, his career before accession, his public actions, his private life, appearance and personality and his death), a procedure more antiquarian than historical; they are full of scandalous gossip; and on the empire in general—its growth, administration and defense—they are largely silent. However, Suetonius exhibits compensating merits, quite apart from the fact that he was not aiming to write history and that the gossip and the lampoons are, in their way, valuable historical evidence. He is free from the bias of the senatorial class which distorts much Roman historical writing, and he is commendably willing to quote documents verbatim.

The earlier *Lives* down to Nero (especially the first two) are much the fullest; for that period a mass of sources was available, already collected and published, whereas for the Flavian period original research had to be done. It is surprising that Suetonius, who, in his position *a studiis*, was ideally placed for the necessary research, should have failed just in this (he quotes no original sources in his account of the Flavians); and the opinion is held by some that he made no attempt to investigate any sources himself but took everything from existing collections. However, it may be that as an antiquarian he was drawn to the documentary byways of the earlier age and had less interest in the Flavian emperors, and it seems likely that posterity owes to his brief tenure of the post *a studiis* such immensely valuable pieces of historical material as imperial wills and private letters.

Suetonius was not incapable of critical analysis of his sources, but he exercised it only on minutiae. He was trying to evaluate the personalities of individuals in terms of the standards and traditional interests of Roman public life and society; and he was ready, like Plutarch, to press into service the "characteristic anecdote," without exhaustive inquiry into its authenticity. His pen pictures of the habits and appearance of the emperors are invaluable; but the "rubric" method of composition made it impossible for him to analyze the development of their different characters.

The *Lives* are exciting to read. Suetonius avoids the excesses of archaism and preciousness to which many authors of his day were prone. He writes with firmness and brevity; he loves the *not juste*, the Greek word for a Greek thing, the correct technicality (this was the direction in which his interests lay, as can be

seen from the titles of his lost works); and his use of this precise vocabulary enhances his pictorial vividness. Above all, he is un-rhetorical and unpretentious, not shrinking from bald lists of facts where they are appropriate, but capable of molding complex events into lucid, well-designed periodic sentences.

**BIBLIOGRAPHY.**—*Editions:* For the whole extant works, see K. L. Roth (ed.), in the "Teubner Series" (1858); for the *Lives of the Caesars*, see M. Ihm (ed.), in the "Teubner Series" (1907; minor ed., 1923); J. C. Rolfe (ed.), in the "Loeb Series," with Eng. trans., 2 vol. (1914); H. Ailloud (ed.), in the "Budé Series," with French trans. (1931–32). All the minor works were edited by A. Reifferscheid (1860); the *De grammaticis* and *De rhetoribus* by R. P. Robinson (1922); the *De poetis* by A. Rostagni (1956); *Index verborum* by A. A. Howard and C. N. Jackson (1922).

*English Translations:* The *Lives of the Caesars* were translated by Philemon Holland (1606; often reprinted) and R. Graves (1957).

*General:* On Suetonius' life, works and place in the history of ancient biography see A. Macé, *Essai sur Suetone* (1900); G. Funaioli in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, vol. iv, 2nd series (1931); W. Steidle, "Sueton und die antike Biographie," in *Zetemata*, vol. i (1951); R. Syme, *Tacitus*, pp. 501–502, 778–782 (1958). (J. A. CR.)

**SUEZ** (AS SUWAYS), the name of a town and governorate in Egypt, and of a gulf of the Red Sea at the head of which they are situated. With Bur Tawfiq (Port Tewfik, included in the governorate) they lie at the southern terminus of the Suez Canal (q.v.), where it joins the Gulf of Suez.

**Governorate and Town of Suez.**—The area of the governorate is 119 sq.mi. (307 sq.km.), and the population (1960 census) was 203,610. The governorate is surrounded by desert and for its water supply relies upon the Sweet Water Canal (opened 1863), which leaves the Nile at Cairo as the Ismailia Canal (Tur'at al Isma'iliyah). Bur Tawfiq, connected with Suez by an embankment, is a creation of the former Suez Canal Company. The harbour is built on land reclaimed from the sea and includes a dry dock 410 ft. (125 m.) long, 100 ft. (30 m.) wide, and 36 ft. (11 m.) deep. There are large quays and separate basins for warships and merchant ships, and the roadstead at the mouth of the canal provides ample room for the assembly of convoys for transshipment.

The site of Suez as a terminus to the old route between Cairo and the Red Sea has long been settled. The Greek settlement of Clysma became in the 7th century the Muslim Kolzum, standing at the southern end of the canal then joining the Red Sea and the Nile. After the Ottoman conquest of Egypt in the 16th century, Suez became a naval as well as a trading station, where fleets were equipped that rivalled the Portuguese for mastery of the Indian Ocean.

An overland mail route from Egypt to India (organized by Thomas Waghorn), including the desert section from Cairo to Suez, was opened in 1837, and in 1857 a direct railway over this route was completed. A further rail link with Cairo via Ismailia was constructed in 1868; this, with the opening of the Suez Canal in 1869, gave new life to the declining settlement. A road now parallels the direct railway. Two pipelines convey refined products and crude oil to Cairo from the refineries and bunkers at Suez. The expansion of the workshops of the Suez Canal Company and the establishment of two oil refineries and an artificial fertilizer factory have brought some diversification to the economy. Most of the 150,000,000 tons of shipping handled annually by Bur Tawfiq is in transit through the canal.

Suez is the port of departure for the pilgrims' sea voyage to Jidda (the port for Mecca, on the Arabian coast), and Ash Shatt, opposite Bur Tawfiq, is a quarantine station for pilgrims returning from Mecca.

**Gulf of Suez.**—This northwesterly arm of the Red Sea separates Africa proper from the Sinai Peninsula and is linked to the Mediterranean by the Suez Canal. Its length, from its mouth at the Strait of Jubal to its head at the town of Suez, is 195 mi. (314 km.). The width of the Strait of Jubal, between Cape Muhammad, the most southerly point of the Sinai Peninsula, and Shadwan Island, is 20 mi. (32 km.; from mainland to mainland, 42 mi. [68 km.]). The gulf is shallow, its maximum depth being about 120 ft. (37 m.). It narrows in four places, being at its narrowest 12 mi. wide.

The Gulf of Suez dates initially from the Oligocene Period,

when sporadic elevations of the land accompanied by great fracturing began the formation of the Red Sea Basin. The great structural depression of the Red Sea-Gulf of Aqaba-Gulf of Suez, between the two ancient Archean blocks of Arabia and North Africa, was formed in the subsequent Miocene and Pliocene periods of the Tertiary Age. The Gulf of Suez, a submerged rift valley, is a continuation of the main Red Sea rift, which is part of the rift system extending from Syria south to Malawi (*see GREAT RIFT VALLEY*). Igneous and metamorphic rocks of the Archean basement flank the southern half of the gulf, although for the most part they are masked by younger limestones and sandstones. Step faulting is severe on the Sinai side, while the strata of the African mainland sag rather than fracture. The shallow Gulf of Suez slopes down regularly to the Red Sea, where, at the Strait of Jubal, there is a sudden drop to a depth of over 3,000 ft. Coral reefs have been built up in the shallow coastal waters, and barrier reefs fringe the island groups at the entrance.

The shores of the gulf are steep only where the older rocks outcrop, as along the central Sinai coast; for the most part the bordering high land is fringed by a waterless coastal plain up to 15 mi. wide dissected by the wadis of occasional or relict streams. There are few harbours, but some capes afford shelter. Settlements are confined to a few fishing and mining villages, notably, on the African mainland coast, Al Ghurdaqah (Hurghada; pop. 4,300) and Ras Gharib (3,800) serving the nearby oil fields. On the Sinai coast the harbour of Abu Zanimah, considered the best on either side of the gulf, serves (by wire ropeway) the neighbouring Umm Bogma (Bujmah) manganese mines. (A. B. M.)

**SUEZ CANAL**, a sea-level waterway, cut through the Isthmus of Suez in the United Arab Republic and connecting Suez on the Red Sea with Port Said on the Mediterranean. It is the shortest maritime route between Europe and the lands lying round the Indian and western Pacific oceans and is one of the world's most heavily used shipping lanes.

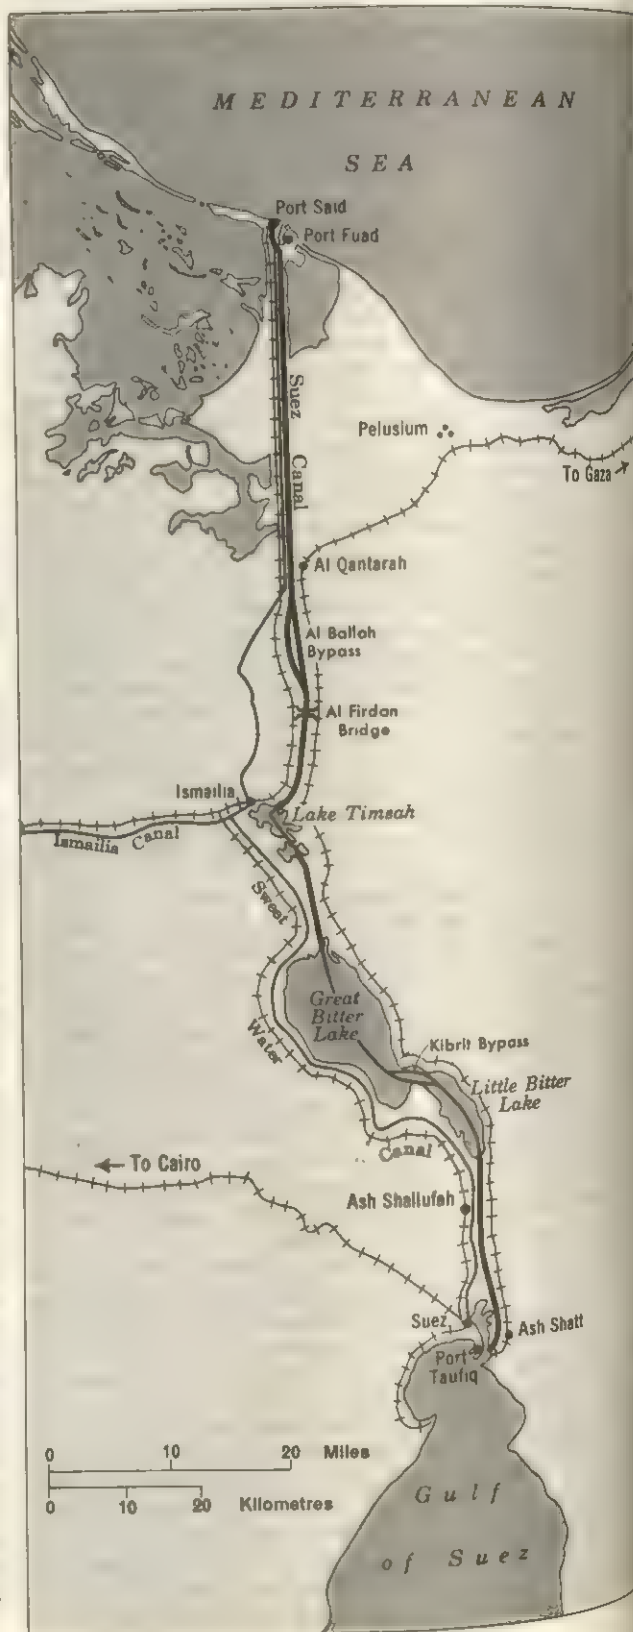

In ancient Egyptian times, possibly in the reign of the pharaoh Sesostri I (early 20th century B.C.), a freshwater canal was dug from the Nile Delta to a point on the Red Sea near the present port of Suez. Its restoration was begun by the pharaoh Necho II about 600 B.C. and completed about 500 B.C. by the Persian conqueror Darius I. During the succeeding Ptolemaic and Roman occupations this canal was several times restored and abandoned. In the 7th century A.D. the Arab commander of Lower Egypt, Amr ibn al-As, reopened this ancient waterway to facilitate the transport of grain from the Nile Valley for shipment to Mecca. In the 8th century the caliph al-Mansur had part of it blocked for military reasons, and the whole canal thereafter fell into final disuse.

**Maritime Canal Projects.**—Among the Venetians in the 15th century and the French in the 17th and 18th centuries were writers who speculated upon the possibility of making a canal through the isthmus. A canal there would make it possible for ships of their nations to sail directly from the Mediterranean to the Indian Ocean and so dispute the monopoly of the East Indian trade that had been won first by the Portuguese, then by the Dutch, and finally by the English, all of whom used the route around the Cape of Good Hope. These schemes came to nothing.

It was not until the French occupation of Egypt (1798–1801) that the first survey was made across the isthmus. Bonaparte, commander of the French expedition, and a group of French officers and scientists spent several days there. J. M. Le Père, Bonaparte's chief lines-of-communication engineer, made a superficial survey of the country between Suez and the site of the ancient city of Pelusium, 20 mi. (32 km.) SE of the present Port Said. He erroneously calculated that the level of the Red Sea was 32 ft. 6 in. (10 m.) higher at high tide than the Mediterranean at low tide. Considering the adverse conditions under which the French surveyors worked, and the prevailing belief in the disparity of levels of the two seas, the error was excusable. Le Père's assumption that there was a considerable difference in the levels of the two seas, and that the construction of a lockless canal was therefore impossible, was uncritically accepted by a succession of subsequent authors of canal projects.

The advent of the steamship and the increasing tonnage and speed of steam vessels drew attention to the advantages of a Suez canal. Technical opinion was long divided between the merits of a saltwater canal through the narrowest part of the isthmus and a freshwater canal, supplied from the Nile, between Alexandria and Suez. A third proposed means of communication between the two seas was by a composite river and road route. The opening of the Mahmudiya Canal in 1820 placed Alexandria in direct river

THE SUEZ CANAL

communication with Cairo and made this overland route, pioneered in 1829 by Lieut. T. Waghorn, a serious, if temporary, competitor to the canal project. In 1830, however, the British government sent Capt. (afterward Gen.) F. R. Chesney to survey the terrain and report on the feasibility of a ship canal. In the course of his survey Chesney found only a slight difference in levels between the Red Sea and the Mediterranean, proving that a lockless canal was an engineering possibility. But his report was laid before the select committee of the British Parliament and for the time forgotten.

A group of engineers, followers of the sociological principles of Claude Henri de Rouvroy Saint-Simon (*q.v.*), with Barthélemy Prosper Enfantin (*q.v.*) at their head, went to Egypt in 1833 and placed before the viceroy a proposal for a Suez canal which the viceroy rejected. In 1841 Arthur Anderson, managing director of the Peninsular and Oriental Steam Navigation Company, with L. M. A. Linant de Bellefonds (Linant Bey), the future Egyptian minister of public works, and two British merchants in Egypt, the brothers J. and G. Gliddon, formed a company to make a technical study for the construction of a sea-level canal between Suez and a site on the Mediterranean near Pelusium. The company based its proposals on the detailed surveys of Linant, who confirmed the accuracy of Chesney's conclusions. Anderson's pamphlet *Observations on the Practicability and Utility of Opening a Communication Between the Red Sea and the Mediterranean by a Ship-Canal* (1843) impressed world shipping opinion.

A public company of international composition, the Société d'Études pour le Canal de Suez, was formed on Enfantin's initiative in 1846 with an initial capital of Fr. 150,000. Among its 12 directors was Robert Stephenson, a British engineer; Alois von Negrelli, a distinguished Austrian railway engineer of Italian descent; and Linant. The company divided itself into national groups, the British with Stephenson as their engineer, the Austro-German with Negrelli, and the French with Paulin Talabot supported by the chambers of commerce of Lyons and Marseilles. The British group failed to send a surveyor to the site, but Stephenson sent plans which he had found in the Admiralty. With his subsequent appointment as engineer in chief of the Alexandria-Cairo Railway construction he ceased his somewhat passive connection with the canal project. Talabot projected a freshwater canal between Alexandria and Suez via the Nile barrage slightly downstream of Cairo. Two other Frenchmen, the brothers A. and E. Barrault, preferred a trace which would describe a great arc from Alexandria eastward through the Nile Delta inland then southward, following the route of the present canal, from Al Qantarah to Suez. Of all the alternative routes suggested to the company, that of Negrelli came nearest to the plan finally adopted.

**The Suez Canal Company Formed.**—At this point Ferdinand Marie, vicomte de Lesseps (*q.v.*) enters the story of the canal. He had served in Egypt as a junior member of the French diplomatic service during 1833–37 and had befriended Mohammed Said Pasha, the future viceroy of Egypt. He had met Waghorn and had been inspired by the imaginative engineering genius of Enfantin. Further, he had studied the surveys of Linant and Negrelli. His opportunity came in 1854 when Said succeeded to the viceroyalty of Egypt. Lesseps, who had retired from the French diplomatic service, hurried to Egypt to congratulate the new viceroy and gain his support for a Suez canal. On Nov. 15, 1854, he unfolded his plan to Said, who at once accepted it. On November 30 a preliminary draft of a concession was signed, subject to ratification by the Ottoman government. The original Turkish text of this agreement accorded less sweeping powers than did the French version. Lesseps' plan closely followed that of Negrelli for the Société d'Études of 1846. The concession provided for the creation of an international enterprise, a Compagnie Universelle du Canal Maritime de Suez, with a chairman appointed by the Egyptian government and a board of directors to be drawn from the chief subscribing nationalities. The French emperor Napoleon III offered Lesseps encouragement and, if necessary, support.

Lesseps well understood the importance of public sympathy, and his pamphlet *The Isthmus of Suez Question*, published in French and English in 1855, was well received. In 1856 the Suez Canal

Company, as it came to be known in the English-speaking world, issued its own journal, *L'Isthme de Suez*, which changed its title in 1869 to *Le Canal de Suez*. With skilful diplomacy the company wooed shipping interests and chambers of commerce and in 1855 invited an international commission of eminent engineers and naval officers to pronounce upon the practicability of the project. The commission met in October of that year and sent a subcommittee to Egypt to make studies on the site.

The plans drawn up by Linant and E. Mougel the year previously were for a canal 91 mi. (146 km.) long, from Suez through the Bitter Lakes to Pelusium, with a lock at each end, which would give a minimum draft of 26 ft. (7.9 m.). The acceptance of their plan would have rendered subsequent widening difficult, and severely limited the size of ships using the canal. In January 1856 the commission presented Said Pasha with a report, published in 1857, in which they recommended a sea-level lockless canal between Suez and the Gulf of Pelusium at an estimated cost of not more than Fr. 200,000,000. Their report removed any lingering doubts as to the technical practicability of the project.

The original act of concession of 1854 was replaced by a more precise and detailed document dated Jan. 5, 1856, to which the statutes of the Suez Canal Company were annexed. By the new act the canal, subject to the approval of the viceroy's sovereign, the Ottoman sultan, was to be open at all times to all merchant ships without distinction or discrimination. The company was empowered to fix and levy transit dues at defined maximum rates. The concession was to run for 99 years from the date on which the canal was opened for navigation, at the end of which period, in the absence of other subsequent arrangements, the canal was to pass to the ownership of the Egyptian government. In addition to the excavation of the maritime canal, the company undertook to excavate a freshwater canal from the Nile at Bulaq to the canal zone. The company's central offices were to be located at Alexandria with administrative headquarters in Paris. The capital of the company was fixed at Fr. 200,000,000 divided into shares of Fr. 500 each. The Egyptian government was to receive 15% of the net profits as a first charge on the company's revenues. The stock issue was only partly successful. France provided half the capital; neither Britain nor the United States subscribed at all, and Said came to the rescue by subscribing Fr. 60,000,000. The response was sufficient to provide the company with its minimum capital requirements, and the directors decided not to wait for the sultan's approval. On April 25, 1859, Lesseps turned the first spadeful of sand at the site of the future Port Said.

**Construction of the Canal.**—The British government, anxious for the security of its communications with India and suspicious of French intentions, opposed the construction of the canal by every means within its power, despite the generally favourable attitude to the canal adopted by British shipping and engineering interests.

The Sweet Water Canal, to supply the installations and towns under construction in the canal zone, was dug during 1858–63 from the Nile at Bulaq, a part of Cairo, to Ismailia, whence a branch was extended southward to Suez. This canal not only provided a channel for the navigation of small ships but also made possible the irrigation of much fertile land along its course.

**Preliminary work**—detailed survey, erection of buildings and plant, concentration of stores, and organization of labour—occupied the first two years, 1859–61, except at Port Said, where land reclamation and harbour work were begun in 1859 by the engineer F. A. T. Laroche. The site chosen for the Mediterranean entrance to the canal, though not the nearest point to Suez, possessed a deeper sea approach than any other site along the neighbouring coast. The quay walls were faced by stone quarried near Alexandria and brought expensively by sea. Concrete blocks for the breakwaters were made at Port Said by Dussaud Frères of Marseilles. By 1868 two breakwaters had been built, on the western mole of which was later placed a colossal statue of Lesseps by E. Fremiet; it was unveiled in 1899 and demolished by the Egyptians in 1956. Water for the workers at Port Said was first produced by condensers, but during 1864–66 two ten-inch (254-mm.) pipes were laid along the artificial causeway from pumps on

the Sweet Water Canal at Ismailia. In 1885 these were replaced by an extension of the Sweet Water Canal (named the Abbasiyah Canal) from Ismailia to Port Said.

Said's death in 1863 removed a staunch, if not altogether uncritical, ally from Lesseps' side. Though enthusiastic for the canal project and personally friendly to Lesseps, Said's successor, Ismail, sought to secure from the Suez Canal Company better conditions for Egypt and himself than were obtained under Said's concession. The company resisted Ismail's demand for the cancellation of Said's undertaking to provide free labour by relays of conscripted Egyptian peasants. With the agreement of the Ottoman government the two parties submitted the dispute to the arbitration of Napoleon III. Under the terms of the arbitration award of July 1864, confirmed by an agreement of Feb. 22, 1866, between Ismail and the company, the latter abandoned its title to 148,000 ac. (approximately 60,000 ha.) of irrigable land and subsidiary freshwater canals and its claim to free labour against a total compensation of Fr. 84,000,000 repayable over a period of 15 years. Though the award was criticized at the time and later as unduly favourable to the company, the finances of which were thereby stabilized, Egypt gained by the company's surrender of property in the canal zone which might well have proved a considerable political embarrassment to both parties. After long delay the sultan ratified the award on March 19, 1866. The company's position was then finally legalized, and the British government, the last powerful opponent of the project, conceded defeat and made active preparations for the opening of the canal by strengthening the dockyard and defenses of Malta.

The organization of work was modified as the construction proceeded. The company retained control of administration and technical management, planning, and the provision of major equipment, while excavation and masonry were entrusted to contractors. At first the company intended to hand over the entire construction to A. Hardon as contractor in chief, but this proved unsatisfactory. The Hardon contract was canceled in 1863, and Hardon was indemnified. From 1862 the technical direction was under F. P. Voisin Bey as chief administrator. After a brief period during which the company undertook direct work, the construction was shared among four contracting firms, each of which undertook to excavate a section of the canal. The first, Dussaud Frères, undertook the harbour works at Port Said; the second, W. Aiton, a Clydeside contractor, was entrusted with the excavation of the 37 mi. (60 km.) of canal south from Port Said; the third contract, 8 mi. (13 km.) of difficult, rocky terrain, was given to A. Couvreux; and the fourth, the largest contract, the excavation of the section between Lake Timsah and Suez, was given to the firm of P. Borel and A. Lavalley, which later took over Aiton's contract as well.

Before the arbitration award of 1866 was promulgated, a maximum labour force of 25,000 Egyptian workmen was employed. After the award, mechanical dredgers of a total of 10,000 h.p. and capable of moving 2,615,900 cu.yd. (2,000,000 cu.m.) of earth a month drastically reduced the number of labourers needed. From then on, an average force of 10,000 labourers and 8,000 European artisans was maintained. The partial substitution of voluntary labour and machines for low-grade forced labour and manual work made it possible to employ more efficient methods. As dredging was found to be cheaper than dry excavation, Borel and Lavalley first flooded sections with water and then dredged. At one time this firm was operating 60 dredgers. Special machinery, such as long-arm dredgers and machines for cutting rock under water, was devised. A particularly difficult section, the rock shelf at Ash Shallufah at the south end of the canal, was removed by 1,300 Sardinian quarrymen. The construction of the canal attracted skilled and unskilled labour from all parts of the Mediterranean and the Middle East.

In February 1862 the Sweet Water Canal reached Lake Timsah and made possible the establishment of a large construction camp at Ismailia. A small pilot saltwater canal from Port Said reached the lake in the following November, by which time excavation was in full swing along the entire construction. On March 19, 1869, the waters of the Mediterranean were admitted to the Bitter Lakes, which within a few weeks became filled and thereby converted into

a navigable channel between the two excavated extremities of the canal. By the early autumn, construction was virtually completed from Port Said to Suez. A total of 97,000,000 cu.yd. (74,162,000 cu.m.) of earth had been excavated. The estimated cost of construction had been not more than Fr. 200,000,000; the actual cost to the end of 1869 was almost Fr. 433,000,000. The work had taken ten years, against an estimate of six.

On Nov. 17, 1869, the canal was officially opened in the presence of foreign sovereigns and princes, statesmen, and notables. A procession of ships headed by the French imperial yacht "l'Aigle," with the empress Eugénie on board, passed through the canal. Several thousand guests representing a cross section of European and Middle Eastern society were invited to the celebrations by the khedive Ismail. Among them were the Algerian patriot and exile 'Abd-el-Kader, the playwright Henrik Ibsen, the novelist Théophile Gautier, and the painter Eugène Fromentin, with a crowd of journalists, military and naval officers, and a representative of the Jockey Club de Paris. Besides a series of lavish celebrations in the canal zone and tours in the Nile Valley an operatic season was arranged in Cairo, and Verdi's opera *Aida* was commissioned for the occasion, though it was not produced until 1871.

The opening of the Suez Canal deprived the Cairo-Suez Railway of most of its economic justification. It was abandoned in 1866 in favour of a new line, longer but serving fertile country, from Cairo to Suez by way of Ismailia, which was opened in the same year. The subsequent growth of the trade of Suez, however, caused the abandoned direct line to be restored in 1930.

After a short period of uncertainty the tonnage of general shipping using the canal steadily increased. In 1892 a new class of traffic appeared when a tanker passed through the canal with a cargo of oil from the Caucasus to the Far East. In 1900 the annual tanker transits had risen to 88.

**International Status.**—The international status of the Suez Canal was long undefined. In 1875 the British government, on the initiative of the prime minister, Lord Beaconsfield, acquired 176,602 Suez Canal shares held by the khedive Ismail for £4,080,000, thus making Britain the largest single shareholder in the company. During the Egyptian nationalist revolt led by Anwar Pasha in 1882, British forces landed at several points on the canal, which for three days was denied to the passage of merchant ships. Although the British action was legalized by a decree of the khedive of Egypt authorizing the British to occupy all the points necessary for the reestablishment of order in the country, Lesseps instructed the canal employees to abandon their work and protested against the British action.

The operation of the canal was complicated by problems arising from the increase of traffic passing through and by disputes between shippers and the company regarding dues. A petition representing over half of the tonnage of shipping using the canal was presented to the British government in 1883 with a request for the construction of a second canal to accommodate the increasing traffic. The government decided in favour of widening and deepening the existing channel, a solution which the company adopted. This, however, still left the international status of the canal unsettled. In 1883 the British government proposed that the canal should remain unfortified, free for the passage of all ships in peace and in war, but that during hostilities there should be a limitation of the period during which a belligerent warship could remain in the canal. A conference of international experts met in 1885 to settle the canal's international status but failed to reach agreement. After lengthy negotiations a convention was signed at Constantinople in 1888 by which the canal was made a corridor for all ships of all nations in peace and in war; acts of hostility in its waters were forbidden.

Britain was not at first a party to the whole 1888 convention, and it was not until the signature of the Anglo-French Agreement of 1904 that it declared its complete adhesion. Spanish warships had been denied transit through the canal during the Spanish-American War of 1898, and a testing time for the agreement came in 1905 during the Russo-Japanese War when a squadron of the Russian Navy passed through the canal without incident, an opera-

tion repeated by Italian vessels during the Italo-Turkish War of 1911-12.

The canal was in theory open to all belligerents during World Wars I and II. In fact, however, the naval and military superiority of the Allied forces in Egypt and the canal zone, and the Allies' decision that there should be no right of asylum within its waters, denied the effective use of the canal to enemy shipping. In the face of much difficulty the Suez Canal Company endeavoured to maintain neutrality during both wars. During World War I, in February 1915, there was heavy ground fighting on the east bank between Ismailia and Suez when a Turkish expedition endeavoured to penetrate the canal defenses. In the course of World War II the canal was repeatedly bombed, machine-gunned, and sown with parachute mines, with surprisingly little delay to traffic or damage to ships. After the armistice between Israel and its Arab opponents in 1949, Egypt denied Israeli ships access to the canal and detained ships suspected of carrying cargoes to and from Israeli ports. Though at the end of both wars the canal defenses were removed and the canal zone was unfortified, British troops were maintained in the zone in varying strengths until 1956.

**Relations with Egypt.**—Relations between the Suez Canal Company and the Egyptian government were from time to time complicated by the presence on Egyptian soil of an international undertaking not fully accountable to Egypt. In 1909 the company applied for an extension of the canal concession for a further period of 40 years from 1968, but the Egyptian government rejected the application. Although the Egyptian representation on the board of the company had progressively increased, there were in 1955 only 5 Egyptian directors as compared with 16 French, 9 British, one Dutch, and one U.S. director.

It was not until July 26, 1956, that a major crisis arose between the parties. On that date, without prior warning, the Egyptian government, under the leadership of Pres. Gamal Abd-al-Nasser (*g.v.*), announced the nationalization of the assets in Egypt of the Suez Canal Company, a unilateral act of seizure embodied in Egyptian Law No. 285 of that year. The management of the undertaking was vested in a state organ created for the purpose, the Suez Canal Authority, which absorbed all the functions of the former company in Egypt. The chief officers of the new authority were a combined chairman and managing director, a secretary general, a chief engineer, and a legal adviser. As a result of the long experience of Egyptian technical administrators, technicians and artisans, floating and shore staff, in maintaining public works in the Nile Valley and harbour installations at the Egyptian ports, the transfer of control was effected with relative ease.

It is unnecessary here to give a full account of the events which led up to the nationalization of the canal or of the long-drawn-out but unsuccessful attempts at negotiation by the maritime powers. The story of these events; of the military action taken by Great Britain, France, and Israel against Egypt; and of the intervention of the United Nations is told in full in *ECVPT: History: The Suez Crisis*.

The physical result on the canal of these violent happenings was that for several months it was blocked by sunken ships and a variety of impedimenta cast into it by the Egyptians to render it unusable. After the UN expeditionary force had arrived in the canal zone in November 1956 the Egyptian government appealed to the UN for help in clearing the canal. The task was carried out with the utmost expedition under the direction of Lieut. Gen. R. A. Wheeler, formerly of the U.S. Army Corps of Engineers. By April 1957 all obstacles had been removed and the canal was once more open to traffic.

In July 1958 the former Compagnie Universelle du Canal Maritime de Suez (Suez Canal Company), renamed Compagnie Financière de Suez (Suez Finance Company), registered in Paris, concluded an agreement with the Egyptian government on compensation. The company was awarded slightly over £E.28,000,000 for the loss of the canal. On Jan. 1, 1963, the United Arab Republic paid the company the final installment of £E.4,000,000.

**Facts About the Suez Canal.**—The Suez Canal is 101 mi. (162.5 km.) long. The length of the excavated section is 92 mi.

(148 km.). The distance of 10 mi. (16 km.) through the artificially raised water level in the Bitter Lakes required little or no dredging. When first opened, the minimum depth along 2½ mi. of the canal was less than 23 ft. (7 m.) at low tide, and the minimum width was 72 ft. (22 m.). After successive widenings and deepenings, the width in 1963 was nowhere less than 179 ft. (55 m.) at a depth of 33 ft. (10 m.) at the banks, and the minimum depth in the channel at low tide was 40 ft. (12 m.). Except in the Bitter Lakes the canal is lined by revetments to protect the banks from ships' wash. The channel allows the passage of vessels having drafts up to 37 ft. (11 m.), and dredging has been undertaken to increase the maximum draft to 40 ft. The maximum permissible speed for laden tankers is 8 mi. (13 km.) an hour and for vessels in cargo or ballast 8.6 mi. (14 km.) an hour. The average transit time has been reduced over the years from 48 to about 15 hours. Bypasses for ships are at Port Said, Al Ballah, and Kibrit.

For years after the opening of the canal Port Said was without railway communication with the rest of Egypt. In consequence the channel between Port Said and Ismailia was impeded by numerous small pilotage and passenger craft which became a danger to ships using the canal. In 1891 the Egyptian government authorized the Suez Canal Company to lay a private light small-gauge railway between Port Said and Ismailia, the nearest station on the state railway, for carriage of passengers, mail, and company's supplies. The light railway was opened for traffic in December 1893. In 1902 the government replaced it by extending the main line northward from Ismailia. The railway track was doubled to Ismailia by 1916 and to Al Firdan by 1917. The railway to As Salihyah was extended to Al Qantarah in 1916 but was dismantled in 1918.

A swing bridge over the canal carrying a railway toward Palestine was erected in 1916 and removed at the request of the Suez Canal Company after the armistice in 1918. The bridge was re-erected during World War II and, after the war, once again removed; railway vehicles thereafter were ferried across the canal. A road and rail swing bridge at Al Firdan, at kilometre 68, carrying the railway to Gaza, was opened in 1954. As the distance between the two piers of the bridge gave an opening of only 197 ft. (approximately 60 m.) for the passage of ships, the bridge formed a bottleneck in the canal and stultified the widening of the channel. It was therefore replaced by a second road and rail bridge, opened in 1964, with approaches sufficiently wide to allow a navigable channel of approximately 485 ft. (148 m.) width.

Ismailia (*g.v.*), laid out in 1863, is the headquarters of the Suez Canal Authority and the location of various installations, including a pilotage tower and a research centre.

The table shows the number and tonnage of ships and the weight of goods that passed through the canal in various years between 1913 and 1963. In 1962, 882 vessels of more than 30,000 gross

*Shipping Through the Suez Canal*

Ships and Cargoes	1913	1938	1955	1963	1964
Ships in transit					
Number of transits	5,083	6,171	14,666	19,146	19,943*
Net tonnage (in 000s)	20,000	34,418	115,756	210,500	227,991
Goods in transit (in 000 metric tons)					
Southward	11,320	7,768	20,082	34,050	38,518
Northward	14,455	21,011	87,426	159,482	172,463
Total	25,775	28,779	107,508	193,532	210,981†

\*Compared with 11,808 transits through the Panama Canal.

†Compared with 70,550,090 long tons through the Panama Canal.

tons and 4,778 of more than 20,000 gross tons passed through the canal.

A marked feature of canal traffic since 1914 has been the increasing percentage of oil. In 1964 no less than 144,661,000 tons of petroleum products passed northward through the canal, almost wholly from Middle Eastern sources, while 6,136,000 tons of petroleum products passed southward. Thus the total oil products in transit northward toward European ports amounted in 1964 to over 84% of the total northbound traffic. Receipts from canal dues amounted in 1963 to more than £E.71,000,000 and in 1964 reached the record figure of £E.77,700,000.

**SUFFOLK, EARLS AND DUKES OF.** The 1st earl of Suffolk, ROBERT DE UFFORD (1298–1369), was one of six new earls created by Edward III in 1337. After taking part in the arrest of Roger Mortimer, earl of March, at Nottingham Castle in October 1330, he became one of the king's most trusted commanders, diplomats, and counselors. The Uffords were a Suffolk landowning family recently risen to prominence; the 1st earl's father, Robert (1279–1316), who was summoned to Parliament as a baron in 1309, was the son of Robert de Ufford (d. 1298), twice justiciar of Ireland in Edward I's reign. Earl Robert fought at Crécy (1346) and Poitiers (1356) and served in almost every campaign between 1340 and 1360. His heir, WILLIAM (1339–82), 2nd earl, narrowly escaped capture by the East Anglian rebels in the Peasants' Revolt of 1381 and later took the lead in suppressing the insurrection in Suffolk. All Earl William's five children predeceased him; on his death the earldom became extinct, and the bulk of the de Ufford estates escheated to the crown.

The extinction of the de Ufford earls made possible the rapid rise of the de la Poles to magnate status; in August 1385, Richard II created MICHAEL DE LA POLE (c. 1330–89) earl of Suffolk. His grandson, WILLIAM (1396–1450), 4th earl, was made a marquess in 1444 and duke of Suffolk in 1448 (see POLE; SUFFOLK, WILLIAM DE LA POLE, Duke of). JOHN DE LA POLE (1442–91/92), 2nd duke of Suffolk, was the son of the 1st duke by his wife, Alice Chaucer, granddaughter of the poet; he married Elizabeth (d. c. 1503), sister of the future Edward IV and Richard III, and survived the Wars of the Roses, having supported in turn Edward IV, Richard III, and Henry VII. His second but first surviving son, EDMUND (1471/72–1513), surrendered the dukedom in 1493 and became earl of Suffolk; he was attainted in 1504 (see POLE, RICHARD DE LA). The male line ended when William, the last survivor of Duke John's seven sons, died in the Tower of London in 1539.

The title of duke of Suffolk, revived by Henry VIII in 1514 for his favourite, CHARLES BRANDON (c. 1484–1545; see SUFFOLK, CHARLES BRANDON, 1st Duke of), became extinct on the death from the sweating sickness of Brandon's sons (by his fourth wife, Katherine Willoughby), Henry and Charles, on July 14, 1551. Frances, Brandon's elder daughter by his third wife, the king's younger sister Mary Tudor (d. 1533), had married HENRY GREY (1517–54), 3rd marquess of Dorset, a great-grandson of Edward IV's queen, Elizabeth Woodville. Well-educated and a strong Protestant, Dorset was a weak and ambitious man; he belonged to the party of John Dudley, duke of Northumberland, and was created duke of Suffolk on Oct. 11, 1551. He supported Northumberland's attempt to make his daughter Lady Jane Grey (1537–54) queen in July 1553, but he was quick to abandon her cause when the plot failed and was pardoned by Queen Mary. His opposition to the queen's plans for her Spanish marriage involved him in Sir Thomas Wyatt's Rebellion in 1554; the dukedom again became extinct after his execution for treason on Feb. 23, 1554.

In 1603 THOMAS HOWARD (1561–1626), Lord Howard de Walden, second son of Thomas Howard (1538–72), 4th duke of Norfolk, was created earl of Suffolk by James I (see SUFFOLK, THOMAS HOWARD, 1st Earl of), and that branch of the Howard family has held the title ever since.

(T. B. P.)

**SUFFOLK, CHARLES BRANDON, 1ST DUKE OF** (c. 1484–1545), English courtier, a personal friend of King Henry VIII, was the husband of Henry's sister Mary and grandfather of Lady Jane Grey. He was the younger son of William Brandon, Henry VII's standard-bearer, killed at the Battle of Bosworth (Aug. 22, 1485), allegedly by Richard III in person. A large, athletic man, young Brandon proved to be about the only member of Henry VIII's entourage capable of standing up to the king in the tourney, a fact which cemented their youthful friendship. On May 15, 1513, Brandon was created Viscount Lisle because (after the death in 1511 of his second wife, Anne Brown) he had contracted to marry Elizabeth Grey, viscountess Lisle in her own right. However, when she came of age she married Henry Courtenay, earl of Devon, to whom the viscountcy was transferred, and Henry instead made Brandon duke of Suffolk on Feb. 1, 1514.

The duke's matrimonial situation remained complicated. In October 1514, Henry VIII's sister Mary married the elderly Louis XII of France, who died within a few months. The English government then hoped to marry her to the new French king, Francis I, and early in 1515 sent Suffolk to promote the match. The choice was unfortunate, for Mary and Suffolk had long been in love, and Mary believed herself to have received a promise from Henry that after her first political marriage she should have a free choice. The pair married (1515) in Paris secretly, thereby incurring the dangers of the English treason law. Henry's wrath was apparently assuaged by Thomas Cardinal Wolsey (or so Wolsey later claimed), and Suffolk soon returned to favour. He had, however, to resolve the difficulty caused by his marriage to his first wife, Margaret Mortimer, who was still alive. Although this first marriage was declared null (c. 1507) by the London Archdeaconry Court on the grounds of an alleged consanguinity, it was not until 1528 that a papal bull resolved the complications and secured the legitimacy of his marriage to Mary.

Suffolk's interests were those of a knightly courtier with military ambitions; all the evidence suggests that he was a handsome giant of solid stupidity. He proved his personal courage in the 1513 campaign against France; but given military command in 1523 and 1542–44 he displayed only incompetence. He played little part in politics or government, though he assisted in the move to overthrow Wolsey in 1529 and for a few years thereafter appeared to be among the leaders of the king's council. Henry made Suffolk responsible for controlling the shire from which he took his title and used him to balance the powerful interest of the Howard family in East Anglia. The dissolution of the monasteries (1536–40) enabled him to build up a sizable territorial estate in Suffolk, but by 1551 his three sons, one by Mary (d. 1533), and two by his fourth wife, Katherine Willoughby, were all dead, and the Brandon interest passed to the descendants of his paternal aunts. Frances, his eldest daughter by Mary, married Henry Grey, 3rd marquess of Dorset, and was the mother of Lady Jane Grey, *de facto* queen of England on Edward VI's death. Suffolk became lord president of the council in 1529 and great master of the household in 1540. He died at the palace in Guildford, Surrey, on Aug. 24, 1545.

(G. R. E.)

**SUFFOLK, THOMAS HOWARD, 1ST EARL OF** (1561–1626), second son of Thomas Howard, 4th duke of Norfolk, was born on Aug. 24, 1561. He behaved very gallantly during the attack on the Spanish Armada. He commanded the expedition which Sir Richard Grenville and the "Revenge" were lost (1591) and held commands in the Cadiz and Islands voyages (1596–97). Created Baron Howard de Walden in 1597 and earl of Suffolk in July 1603, he was lord chamberlain of the royal household from 1603 to 1614 and lord high treasurer from 1614 to 1618, when he was deprived of his office on a charge of misappropriating money. He was tried in the Star Chamber and was heavily fined.

Suffolk's second wife was Catherine (d. 1633), widow of Richard Rich, a woman whose avarice was partly responsible for her husband's downfall. She shared his trial and was certainly guilty of taking bribes from Spain. One of his three daughters was the notorious Frances Howard, who instigated the poisoning of Sir Thomas Overbury (q.v.). The earl died on May 28, 1626, in London.

(R. B. Wm.)

**SUFFOLK, WILLIAM DE LA POLE, DUKE OF** (1396–1450), second son of Michael de la Pole, 2nd earl of Suffolk, served the early part of his career in the wars against France and the later years of his life in seeking peace with that country. He was born on Oct. 16, 1396, at Cotton, Suffolk. Suffolk served in all the later French campaigns of the reign of Henry V, and in spite of his youth held high command on the marches of Normandy in 1421–22. In 1423 he joined the earl of Salisbury in Champagne and shared his victory at Crevant. He fought under John, duke of Bedford, at Verneuil on Aug. 17, 1424, and throughout the next four years was Salisbury's principal lieutenant in the direction of the war. When Salisbury was killed before Orléans on Nov. 3, 1428, Suffolk succeeded to the command. After the siege was raised, Suffolk was defeated and taken prisoner by Jeanne d'Arc at Jargeau on June 12, 1429. He was soon ransomed, and during the next two years was again in command on the Norman frontier. He returned to England in Nov. 1431, after more than 14 years' continuous service in the field.

In the next decade, as a royal household official and a supporter of the predominant faction of Cardinal Beaufort, Suffolk acquired a considerable influence in the government, which he used mainly to further his own interests. Greedy and unscrupulous, he showed himself unusually grasping even in that mercenary age. He acquired a large number of wardships and offices of profit in the king's gift, and his agents made the heavy hand of his lordship felt throughout East Anglia, where his principal estates lay. It was not until 1443 that the retirement of Cardinal Beaufort brought Suffolk reluctantly to the forefront of politics. Like Beaufort, Suffolk had a genuine desire to achieve a peaceful settlement with France, but he had no clear and practical plan for obtaining peace without disgrace, and he shirked necessary but unpopular decisions. His first success (for which he was made a marquess) was the securing in 1444 of a two years' truce and the hand of Margaret of Anjou for Henry VI. Yet soon afterward the English government was forced to surrender Anjou and Maine in return for a further extension of the truce, a concession which increased Suffolk's growing unpopularity at home. Rumour, though without sufficient reason, made Suffolk responsible for the death of his rival, Humphrey, duke of Gloucester, in Feb. 1447. Another critic of the government, Richard, duke of York, was replaced in his French command by the incompetent Edmund Beaufort, duke of Somerset. Suffolk's promotion to a dukedom in 1448 marked the height of his power.

The difficulties of his position may have led him to give some countenance to a treacherous attack on Fougères during the time of truce (March 1449). The renewal of the war and the loss of all Normandy were its direct consequences. When parliament met in Nov. 1449, the whole Suffolk administration came under attack. The treasurer, Adam Moleyns, bishop of Chichester, was forced to resign, and on Feb. 7, 1450, the commons presented articles of accusation against Suffolk himself, dealing chiefly with alleged maladministration and the ill success of the French policy; there was a charge of aiming at the throne by the betrothal of his son to the little Margaret Beaufort. Suffolk denied the accusations. Ultimately the king sentenced him to banishment for five years. Suffolk left England on May 1. He was intercepted in the channel by the ship "Nicholas of the Tower," and next morning was beheaded in a little boat alongside.

Popular opinion at the time, followed by Yorkist chroniclers and Tudor historians, judged him a traitor, and later legend made him a paramour of Margaret of Anjou. These charges are not supported by any reliable evidence, and probably Suffolk was unfortunate in being made a scapegoat for an unpopular and corrupt administration and policies for which others were as much responsible as he.

Suffolk's wife, Alice, was widow of Thomas, earl of Salisbury, and granddaughter of Geoffrey Chaucer. By her he had an only son John, 2nd duke of Suffolk.

**BIBLIOGRAPHY.**—Suffolk's character and policy have been the subject of much discussion: see W. Stubbs, *Constitutional History of England* (1880); C. Oman, *The Political History of England*, vol. vi (1906); C. L. Kingsford, *Prejudice and Promise in Fifteenth Century England* (1925); K. B. McFarlane in *Cambridge Medieval History*, vol. vii

(1936). Besides the authorities for his career listed in the *Dictionary of National Biography*, reference should be made to the series of *Calendars of Patent and Close Rolls*. (C. D. R.)

**SUFFOLK**, an eastern county of England, is bounded north by Norfolk, south by Essex, west by Cambridgeshire and the Isle of Ely, and east by the North Sea. Its area is 1,481.7 sq.mi. including Ipswich, the county town.

**Physical Geography.**—The general contour of the county is that of a low-lying plateau, but near Denston, in the southwest, the ground rises to over 400 ft. (122 m.). The scenery is varied. In the northwest is the Breckland where the Upper Chalk escarpment of the Chilterns, which continues through Suffolk and on to the Lincolnshire Wolds, is covered by light sands which would be blown away but for their covering of heath. Many plants and insects native to this area are found nowhere else, and the abundance of flints made Brandon for centuries the centre of a flint-knapping industry, now obsolete. The heath is in part giving place to the coniferous plantations of the Forestry Commission.

To the east the chalk is overlaid by the London clay and the crag deposits of the Pliocene, the rich and specialized fauna of which attracts paleontologists throughout the world. These formations are themselves overlaid first by a broad belt of glacial boulder clay running from the northeast to the southwest of the county, and second, near the coast, by sands and gravels. The boulder clay region, known in part as "High Suffolk," was once blanketed by forest but is now fertile farmland. It is intersected by many shallow river valleys and is notable for its fine villages and small towns such as Chelsworth, Kersey, and Lavenham in the Stour (*q.v.*) Valley, made famous by the paintings of John Constable; Beccles (*q.v.*) and Bungay in the Waveney Valley; Framlingham (*q.v.*), and Peasenhall. The coastal region, known as the sandlings, like the Breckland, is marked by great stretches of heath and conifers. It is divided up by broad tidal estuaries bordered by alluvial deposits, such as the Stour, Orwell, and Deben, formed by the subsidence, begun in Neolithic times and possibly still continuing, which extended the tidal range of the sea far inland. Over a thousand acres have been protected as nature reserves; areas of special scientific or historic interest, such as Minsmere, Staverton Thicks, a remnant of the primeval forest, and Havergate Island, the only British home of the avocets, are also protected. (In 1963 the National Trust owned 2,000 ac. and protected 267 ac.) The coastline is very sensitive to tidal action, particularly erosion, which has since the 14th century led to the virtual extinction of the once flourishing port of Dunwich (*q.v.*). The last millennium has seen the formation of the ten-mile-long spit of shingle extending from the mouth of the Alde to Weir Point.

**History.**—Excavations at Hoxne provide definite evidence that Paleolithic man occupied the region as early as the Great Interglacial Period (*c.* 250,000 B.C.). The culture was Acheulean. Upper Paleolithic, Mesolithic, and Neolithic are found at various sites. At Creeping St. Mary, Neolithic Rinyo-Clactonian ware was associated with cremations. The Beaker folk are found both near Ipswich and in the Breckland. The Bronze Age saw a penetration from the west along the Icknield Way; barrows of the Middle Bronze Age have been excavated at Brightwell, and Later Bronze Age urnfields demonstrate a spread from the east by way of the valleys. Iron Age "A" settlements are found principally on the light lands, and Iron Age "B" is represented by a chariot burial near Mildenhall (*q.v.*). Notable Belgic finds come from a cemetery at Boxford and a settlement at Burgh, near Woodbridge.

Along with Norfolk, Suffolk formed part of the kingdom of the Iceni. A bronze head of the emperor Claudius I, dredged from the River Alde at Rendham, may represent jettisoned spoil from the sack of Colchester during the rebellion of Boadicea (Boudicca) in A.D. 60. Excavations near Baylham have revealed a Claudian settlement beneath the Roman road from Colchester to Venta Icenorum; air photography disclosed a camp, possibly of this period, near Ixworth, in an area containing several villa sites. A statuette of Nero from Baylham and a plaque of Mithras from Whitton (Ipswich) have a religious connotation. The notable Mildenhall treasure (in the British Museum, London) was buried at the time of the Saxon raids. Burgh castle still stands, a fort of

the Saxon shore, and a print of the 18th century shows such a fort at Walton (Felixstowe).

The earliest evidence of Saxon settlement comes from the pagan burial grounds at Ipswich (*q.v.*) and Lackford. The remarkable ship burial at Sutton Hoo (*see* SUTTON HOO SHIP BURIAL), near Rendlesham, seat of the East Anglian monarchs, throws new light on the aesthetic standards of the time and, along with the pottery evidence, stresses the importance of the continental contacts of the 7th century. The effects of the Danish invasions of the late 9th century, and of the Viking invasions of the late 10th, though locally severe, seem to have stimulated rather than retarded the development of Suffolk, and by the Norman Conquest Suffolk and Norfolk together formed the most populous and prosperous region of England. During this period the famous abbey of Bury St. Edmunds (*q.v.*), the ruins of which are still extant, was founded as a resting place for the bones of King Edmund, martyred by the Danes in 869. The jurisdiction of the abbey extended over eight and a half hundreds, now forming the basis of the administrative county of West Suffolk. At about the same time a "liberty" consisting of five and a half hundreds in East Suffolk was granted to the prior and convent of Ely which passed to the dean and chapter of Ely Cathedral in 1541. The remaining hundreds, called the "Geldable," were under the jurisdiction of the sheriff who was appointed jointly for Norfolk and Suffolk until 1575. (*See* also EAST ANGLIA.)

The centuries immediately following the Norman Conquest saw the construction of a number of castles, two of which, Eye (*q.v.*) and Clare, became the centres of great honours. The most important remains are to be found at Framlingham and Orford (both in the custody of the Ministry of Works), Wingfield, and Mettingham. A number of small religious houses were also founded, including Clare Priory, which was dissolved in the 16th century and reoccupied in 1953, after a lapse of 400 years, by the Order of St. Augustine. Little Wenham Hall is a notable example of a 13th-century fortified dwelling house.

Cloth weaving, based on a supply of local wool, flourished from the 14th to the 16th century, and Lindsey and Kersey woolens were famous throughout Europe. The prosperity engendered by this industry is apparent in the churches, the majority of which are of the Decorated and Perpendicular periods, with open roofs, good woodwork, and fine fonts. Long Melford, with its remarkable Lady Chapel, Lavenham, Blythburgh, and Southwold are magnificent examples. In the main the churches of all periods are constructed of flint, and no less than 41 have early round flint towers, the most notable at Little Saxham and Wortham.

There were serious uprisings in West Suffolk against Bury Abbey in the 14th century, but the county was relatively unaffected by the Wars of the Roses in the 15th century, in spite of the strong Yorkist flavour imparted by the presence of one of the chief seats of the dukes of Norfolk at Framlingham.

Though strong Protestant influences penetrated the county through Ipswich in the early 16th century, Mary Tudor derived much of the support for her claim to the throne from Suffolk. However, Puritanism did establish itself as a dominant force in the later 16th century and many families emigrated to the New England colonies of America for religious as well as economic reasons. During the Civil War the county was strongly parliamentary and the local gentry actively supported the Association of the Eastern Counties. Hengrave and Helmingham halls, both of the early 16th century, are fine examples of the domestic architecture of the period.

The 17th and 18th centuries saw the rapid decline of cloth weaving, but the prosperity of agriculture led to the building of such fine houses as Heveningham, designed by James Wyatt, with its superb interior decorations, and Ickworth (since 1956 owned by the National Trust), built about 1794–1830 by the 4th earl of Bristol, bishop of Derry, with its rotunda and great curving wings.

As a coastal county, the history of Suffolk has been much influenced by the sea. Fishing fleets left the ports for cod and ling from Iceland, and herring and mackerel from the North Sea. A big fish trade was carried on with Flanders. It was from Orwell Haven that Edward III sailed in 1340 to win the Battle of Sluys against

the French; Thomas Cavendish of Trimley St. Martin was the third man to circumnavigate the world; and in the 17th century Suffolk was the base for sea operations against the Dutch. The threat of invasion during the Napoleonic period led to the erection of the many surviving Martello towers, for example, at Aldeburgh and Felixstowe (*qq.v.*).

**Population and Administration.**—Suffolk is divided into three major administrative units: East Suffolk covering 855.3 sq.mi. with a population (1961) of 225,661; West Suffolk covering 610.8 sq.mi. with a population (1961) of 128,918; and Ipswich covering 15.6 sq.mi. with a population (1961) of 117,395.

East Suffolk has five municipal boroughs, seven urban and seven rural districts; West Suffolk has two municipal boroughs, three urban and six rural districts. Ipswich, in East Suffolk, is a county borough and the county town.

Prior to the Reform Act of 1832 the county returned 2 members to Parliament and 14 members from its seven boroughs. By this act the boroughs of Orford, Aldeburgh, and Dunwich were disfranchised. From 1948 the county constituted five divisions, each returning one member. Until 1872 the county had a single commission of the peace and quarter sessions were held in four divisions, one each for the liberties of Bury St. Edmunds and St. Etheldreda, and one each for the two parts of the "Geldable" based on Beccles and Ipswich, respectively. After 1872 the numbers were reduced to two, namely East and West Suffolk. Since 1951 separate commissions of the peace have been in force for East and West Suffolk. There are separate commissions for Ipswich and Bury St. Edmunds. Since 1888 East and West Suffolk have been governed by their own county councils.

In 1837 the archdeaconry of Sudbury (*q.v.*), roughly covering the area now known as West Suffolk, was transferred to the Ely diocese. In 1914 the present diocese of St. Edmundsbury and Ipswich was founded and comprises the whole of Suffolk less the deaneries of Lothingland and Flegg.

**The Economy.**—Agriculture was, and still is, the greatest employer of labour in Suffolk. After the breakup of much of the pasture during the Napoleonic Wars, it became one of the principal grain-growing counties. More than half the land is arable, and the numbers of cows, sheep, and pigs fluctuate considerably. The main crops, in order of importance, are barley, wheat, oats, sugar beet, clover and grass (for hay), mangels (with turnips and swedes), peas, and beans. Horse breeding is declining—including the famous Suffolk Punch—but Newmarket (*q.v.*) retains its pre-eminence as the centre of the bloodstock and racehorse industry.

The cloth industry was replaced during the 18th and 19th centuries by textiles such as sailcloth, coconut fibres, horsehair, and clothing. Besides textiles the most important manufactures relate to agriculture. Agricultural machinery is especially important at Ipswich, Bury St. Edmunds, and Stowmarket. Grain milling and malting are extensive and fertilizers are made at Ipswich. There are sugar-beet factories at Sproughton and Bury St. Edmunds, and quick frozen foods are processed at Lowestoft (*q.v.*). Heavy engineering is also found at Ipswich, and shipbuilding at Lowestoft. Ipswich, Beccles, and Bungay are important for printing. Paint is manufactured at Stowmarket, and at Branham a large plastic works has been established. Fishing is mainly concentrated at Lowestoft. In 1962 the building of a nuclear power station for the Central Electricity Generating Board was begun at Sizewell on the coast, 2 mi. E of Leiston. The port of Ipswich takes vessels of up to 25 ft. draught, and with Lowestoft Harbour and the reopened Felixstowe dock, handles a considerable import trade. British Railways (Eastern region) serves the county with a main line from London (Liverpool Street) to Ipswich, and branch lines to other parts. There are civil aerodromes at Ipswich and Newmarket Heath (a private landing ground).

**SUFFREN, PIERRE ANDRÉ DE** (1729–1788), French admiral noted for his contribution to the advancement of French naval strategy and tactics. Born at Saint-Cannat, near Aix-en-Provence, on July 13, 1729, into the noble family of Suffren de Saint-Tropez, he was very early admitted into the Order of the Hospital of Saint John of Jerusalem (Knights of Malta), in which he eventually rose to the rank of bailli. Entering the French corps of *Gardes de la Marine* (naval guards) as a cadet in 1743, during the War of the Austrian Succession, he was soon sent to sea. In 1747 he was impressed by Adm. Edward Hawke's concentration of fire on the French rearguard in the Battle of Cape Finistère, in which Suffren was among the prisoners taken. Released on the peace of 1748, he went to serve with the Maltese galleys. In the French service again at the start of the Seven Years' War (1756), he saw, in action off Minorca, how opportunities were missed by rigid adherence to "line ahead" formation.

In April 1778, as captain of a ship in the squadron under Adm. C. H. d'Estaing (q.v.), Suffren sailed from Toulon for North America to help the insurgent colonists against the British. In his private letters he sharply criticized his admiral's conduct.

Suffren's own ideas, inspired by the example of the 17th-century Dutch admiral De Ruyter, were clear enough: sea warfare can play a decisive part in strategy; and in naval engagements the essential factors are retention of the initiative, speed, and watchfulness for the means and opportunity of concentrating a maximum of strength against a fraction of the enemy's line. He reacted, just as Hawke and Samuel Hood on the British side did, against the sterile caution of engagements in line and against the failure to appreciate the strategic role of a fleet. A man of violent temper and of prodigious energy, explosively choleric, and vulgar in his manner, Suffren nevertheless had a quick and subtle mind and a kind heart. His boundless ambition was directed only toward the glory of achievement.

A mission to the Indian coast gave him a chance of proving his ability, with means so limited that he had often to resort to improvisation. On his way out (April 1781), he attacked a British fleet anchored at La Praya (Praia), in the Cape Verde Islands: his motive—surprising to contemporary strategists—was to promote the success of a land enterprise, the French occupation of the Cape of Good Hope, which the British fleet was going to contest. In Indian waters he fought engagements off Sadras (near Tirukkalikunram; in February 1782), off Providien (in April), off Negapatam (Nagapattinam; in July), off Trincomalee (in September), and off Cuddalore (in June 1783). In this remarkable series of engagements he tried to teach his captains how to isolate groups of enemy vessels and thus destroy a squadron piecemeal. His efforts were not invariably successful, and their originality was scarcely understood by his superiors: but public opinion in France was enthusiastic for him. On his return after the peace of 1783 he was made a vice-admiral.

Suffren died in Paris on Dec. 8, 1788, in circumstances still debated by historians (whether from apoplexy or from a duel). See R. Boutet de Monvel, *La Vie martiale du Bailli de Suffren* (1929); E. Davin, *Suffren* (1947). (L. NL.)

**SUFISM** (TASAWWUF), the name by which Islamic mysticism came to be known in the 8th or 9th century A.D., is formed from the Arabic word *sufi*, meaning "wearer of wool," woolen dress having been strongly associated with spirituality even in pre-Islamic times. The Sufis are also generally known as "the poor [in spirit]," *fugara*, plural of *fagir*, in Persian *darwish*, whence the English words "fakir" and "dervish."

**Sufi Doctrine and Practice.**—All Muslims must believe that there is no absolute reality but God (see ISLAM: *Muslim Theology*) but only the Sufi carries this doctrine to its ultimate conclusion. For him, reality (*al-Haqq*) is that which is as opposed to that which is not. Therefore God alone is, whence the term "oneness of being." The doctrine of the oneness of being, which Western scholars term monism, is expressed by several verses of the Koran, such as "Wheresoe'er ye turn, there is the face of God"

(2:115) and the all-inclusive definition of God: "He is the first and the last and the outwardly manifest and the inwardly hidden" (57:3). This last verse cannot, however, be taken pantheistically, nor does any Sufi imagine God to be the sum of all existing things, for it is an essential aspect of God's oneness that he has no parts. The doctrine of oneness of being means that each apparently separate thing is an illusory veil over the one indivisible plenitude of the absolute, infinite, and eternal truth. A 13th-century Sufi, 'Abd Allah al-Balyani, said, "When the secret of an atom of the atoms is clear, the secret of all created things both external and internal is clear, and thou dost not see in this world or the next aught beside God."

The veil of illusion cannot be pierced by any human faculty, but vision of the truth is nonetheless possible because, owing to the extreme nearness of God, expressed in the koranic verse "We [God] are nearer to him [man] than his jugular vein" (50:16), human sight is liable to be overwhelmed by the divine sight. "The sight o'ertaketh him not, but he o'ertaketh the sight" (6:103); "God cometh in between a man and his own heart" (8:24). The key to inward vision lies in the verse "All things in creation suffer extinction and there remaineth the face of thy Lord in its majesty and bounty" (55:26–27). It is on this verse, continually quoted by the mystics of Islam, that the Sufi doctrine of extinction (*fana'*) is based.

The path of Islamic mysticism may be said to consist in anticipating the inevitable ultimate extinction of all things other than God. The prostration in the ritual prayer, which for the average Muslim symbolizes an undefined humility before God, is for the Sufi no less than the absolute humility of extinction of the ego so that only God, the true self, will remain. Similarly, when he performs the ritual ablution the Sufi aspires to absolute purification through the washing away of everything except God. In reciting the Koran he aspires to be as it were drowned in the koranic ocean of uncreatedness, one of the basic tenets of Islam being that the Koran is the uncreated Word of God. These examples show that in practice as well as in doctrine the difference between the Sufi and the average Muslim is not one of form but of the understanding and aspiration that lie behind the form.

The whole of Sufism as regards both doctrine and practice is summed up in the saying of the Prophet (called a "holy tradition," or *hadith qudusi*, because in it God speaks in the first person) quoted by the great traditionist al-Bukhari:

Nothing is more pleasing to me as a means for my slave to draw near to me, than the worship that I have made binding upon him. And my slave ceaseth not to draw near to me with added devotions of his free will until I love him. And when I love him I am the hearing wherewith he heareth and the sight wherewith he seeth and the hand wherewith he smiteth and the foot wherewith he walketh.

As this tradition implies, the practices of the Sufis are of two kinds: the obligatory forms of worship that are binding on all Muslims, namely the five daily ritual prayers, paying the legal alms, fasting in the month of Ramadan, and making the pilgrimage to Mecca if possible; and voluntary worship, such as reciting the Koran and litanies, fasting apart from Ramadan, keeping vigils, making spiritual retreats, and above all invoking the name "Allah" and other divine names. All these practices, the voluntary as well as the obligatory, were undoubtedly the practices of the Prophet and his chief companions.

**Historical Development.**—It is only in secondary respects that there can be said to have been any development in Sufism, or for that matter in Islam as a whole, since the time of the Prophet. The first Islamic community, not unlike the first Christian community, was a fairly homogeneous whole with a strong mystical bias. But, as the historian Ibn Khaldun points out, in and after the second generation the spread of worldliness caused a general falling away, which left the mystics a much more distinct class than they had been before; hence the need of a special name to denote them. Different groups were soon formed in Sufism, which led finally to the formation of orders or brotherhoods (sing. *tariqa*; pl. *taruq*), which became more and more fully organized as time went on.

As regards certain details of Sufi observance, Mohammed had

recommended the recitation of several litanies a specified number of times. From the need to keep count, the Sufis quickly took to using knotted cords and then beads. The repetition of formulas not only leads to the use of rosaries but is also conducive to rhythmic movements of the body. Some of the collective dances practised in many of the Sufi orders are so simple that they could have easily crystallized in one generation from the spontaneous isolated movements of single individuals; and once such practices had been established, it was natural that here and there more complex dance movements should be developed. The Mawlawi order of Sufis, founded by Jalal-ud-din Rumi (q.v.), is better known to the West as the "whirling" or "dancing dervishes" because of the dance their founder prescribed for them. Such practices, however, have never been considered as more than aids to concentration.

It was not long before the Sufis began to write treatises. In one of these al-Kalabadhi (d. A.D. 995) says: "Then [after the second generation] spiritual desire diminished and purpose flagged: and with this came the spate of questions and answers, books and treatises." What Western scholars tend to take as a mark of progress was clearly not considered so by the Sufis themselves. "Take knowledge from the breasts of men, not from words" and "Whoso knoweth God, his tongue flaggeth" are among the most often repeated Sufi maxims.

But words are sometimes necessary. Conscious that the rest of the community had ebbed away from them, and themselves struggling against the current of this ebb, the Sufis of the 9th and 10th centuries felt driven to go to lengths previously unknown in Islam, not only as regards asceticism but also as regards doctrinal formulation. Abu Yazid al-Bistami in the 9th century went so far as to say "Glory be to Me! How great is My majesty!" Such utterances were liable to bring the Sufis into conflict with the more exoteric authorities, and in A.D. 922 al-Hallaj (q.v.) was put to death for saying "I am the Truth."

On the other hand, the inevitable chasm that exists between mysticism and the more external aspects of religion has been bridged in every Muslim generation by men who were at the same time members of Sufi orders and eminent authorities in one or more of the outer domains of Islam. The most famous of these "bridges" is probably al-Ghazzali (q.v.), the great canonist and theologian, who devoted his latter years to the mystic path and wrote among other things a treatise in praise of Sufism as the highest kind of life and as the only sure antidote to skepticism. His much younger contemporary, 'Abd al-Qadir al-Jilani (d. A.D. 1166), "the sultan of the saints," founded the Qadiri order, which within one generation after his death had spread to most parts of the Islamic world. Today the largest Sufi brotherhoods are the Qadiri and the Shadhili, the latter founded by Abu'l-Hasan al-Shadhili (d. A.D. 1258).

Even the most summary account of Sufism would not be complete without a mention also of the Spanish-born mystic Ibn Arabi (q.v.), known as "the greatest sheikh," who in a sense belongs to all the orders in virtue of his writings, a vast and much drawn on treasury of mystical prose and poetry. Perhaps the two greatest poets of Sufism, however, are his two contemporaries, the Egyptian Ibn al-Farid (q.v.), known as "the sultan of the lovers," whose famous wine song begins with the words "We have drunk to the memory of the beloved a wine wherewith we were made drunk before the vine was created"; and the founder of the "whirling dervishes," Jalal-ud-Din Rumi, whose *Mathnawi* is considered to be one of the finest works in Persian poetry. One of the works most consulted by Sufis themselves is 'Abd al-Karim al-Jili's early-15th-century treatise *al-Insan al-kamil* ("Universal Man"), which presents all that is essential to Sufi doctrine in a remarkably clear and accessible form. To al-Jili is owed the illuminating symbolism of water and ice as representing, respectively, God and creation in their apparent difference and secret identity.

**Sufism Today.**—Such deviations as drug taking, sorcery, juggling, snake charming, and fire eating, the features most associated with Sufism by many Westerners, have affected only a small fraction of the whole. The orders still comprise thousands of deeply serious and devout men and women in nearly every Islamic coun-

try, and of all Muslims these are probably the most aloof and inaccessible to Europeans. Only in Turkey and in Saudi Arabia are the orders officially forbidden, for almost opposite reasons. Mustafa Kemal Atatürk banned them (1925) as the most conservative element in Islam, knowing that they would be a great impediment to his secularization of Turkey. On the other hand, the puritanical Wahhabi sect that rules Saudi Arabia is hostile to the orders because their conservatism is not narrow enough and because, in particular, they encourage people to visit the tombs of the saints.

Of the approximately 70 Sufi orders in existence today, the following are among the most important:

- 'Alawi, branch of the Darqawi-Shadhili, in Algeria, Morocco, Syria, Jordan, Israel, Aden, and Ethiopia
- Bektashi, originally in Turkey, now chiefly in the Balkans
- Burhani, in Egypt
- Darqawi (Derqawa), a branch of the Shadhili, in Morocco, Algeria, Egypt, Lebanon, Ceylon
- 'Isawi, a branch of the Shadhili, in Morocco, Algeria, and Tunisia
- Khalwati, a branch of the Suhrawardi, originally in Khurasan, with branches in various parts of the Islamic world
- Madari, in India-Pakistan
- Mawlawi (Mevlevi Turkish), originally in Turkey, spread to other parts of the former Ottoman Empire
- Naqshabandi, originally in Turkistan, with branches in all Islamic countries of the Near East and in central Asia, China, India-Pakistan, and Indonesia
- Ni'matallah, in Iran, a descendant of the Qadiri
- Qadiri, originally in Baghdad, with branches all over the Islamic world
- Rahmani, a branch of the Khalwati in Algeria
- Rifa'i, originally in southern Iraq, with branches in Syria and Egypt
- Sanusi (see *SENUSSI*)
- Shadhili (Shazili), with branches all over the Islamic world
- Shattari, in India-Pakistan, Malaya, and Indonesia
- Suhrawardi, founded in Baghdad, now in Afghanistan and India-Pakistan, with many branches elsewhere
- Tijani, in North and West Africa and Sudan

**Influences Received and Exerted.**—The influences on Sufism from outside have been enormously exaggerated. Probably the chief influence was Neoplatonism, but even this was confined mostly to terminology and to methods of doctrinal exposition.

As regards the influence exerted by Sufism on non-Islamic communities, it has made many converts to Islam. The Tijani order, for example, may be said to have taken parts of West Africa by storm, and some Muslim communities there are Sufi almost to a man. It was also through Sufism, as representing the most intellectual aspect of the religion, that many Hindus were converted to Islam. Dara Shikuh, the Sufi brother of the 17th-century Mughal emperor Aurangzeb, remarked that the only difference between the Hindu doctrine of *advaita* (nonduality) and the basic doctrine of Sufism is one of terminology.

Today, with the vast increase in Western knowledge of Islamic mysticism, more than one attempt has been made to start non-Islamic Sufi movements in the West, but the real Sufis would not recognize in this anything but dilettantism.

Apart from conversions, the influence of Sufism on other mysticisms is impossible to assess. All mysticism is fundamentally the same, and two forms may correspond closely even in detail without being in any way mutually indebted. (See *MYSTICISM*) There was no doubt a certain interchange of ideas between Sufism and Christianity. The Knights Templar, for example, almost certainly made intellectual contacts with the Sufis; so did St. Francis, it is said; and al-Ghazzali was well known to Western Europe in the Middle Ages, and some of his works were widely read in Latin translations.

**SUGAR.** The familiar white crystalline substance known as sugar is the organic chemical compound sucrose having the formula

mula  $C_{12}H_{22}O_{11}$ . Chemists designate a large group of related compounds as sugars but these are usually referred to by specific names: corn sugar (glucose, dextrose), fruit sugar (fructose, levulose), milk sugar (lactose), etc. All sugars are members of the larger group known as carbohydrates (*q.v.*). Of the more than 65,000,000 tons of sugar produced annually in the world, about 60% comes from sugarcane and 40% from sugar beets. Minor sources of sucrose are the maple tree *Acer saccharinum*, sorghum cane (known by many different names), and certain classes of palms, primarily the wild date palm *Phoenix sylvestris*; all are produced on a small-farm basis largely for local consumption, although the total output may reach fairly large proportions (see MAPLE SIRUP; SORGHUM; DATE PALM; PALM).

Sugar in the mature cane or beet has the same chemical composition as the product that reaches the consumer; that is, the basic character of the sucrose remains unchanged from field to final product. Sugar is formed in the stalk of the cane and the root of the beet by the process of photosynthesis by which the action of sunlight on the chlorophyll of the leaves combines carbon dioxide from the air and water from the soil, giving off oxygen in the process.

### SUGARCANE

**History.**—Utilization of sugarcane dates from antiquity but the beet as a source of sugar is a development of the past 150 years. Authorities now generally agree that sugarcane originated in New Guinea and was transported to southern Asia in prehistoric times. The first references in the literature relate to the growth of sugarcane in northern India in the 4th century B.C. The word "sugar" is derived from the Sanskrit *śarkarā*, which may be traced to practically all modern languages. The Sanskrit for solidified sugar is *khandā*, from which comes the word "candy." The first positive evidence of sugar in solid form dates from Persia, about A.D. 500.

The Arabs spread the culture of sugarcane through northern Africa and southern Europe at the same time that the Chinese, who introduced methods of extracting sugar from the cane, carried it to Java and the Philippines. Commercial manufacture developed in Egypt during the 9th and 10th centuries, but not until the "Age of Discovery" made sugar from the Americas available in large supply did it cease to be a scarce luxury dispensed by apothecaries. Practically every newly discovered area was promptly supplied with cane for planting. Columbus carried sugarcane to Santo Domingo on his second voyage in 1493 and the culture spread to Cuba and other islands of the Caribbean. Cortés, Pizarro, and other explorers took cane to the mainland of Central and South America, with the result that by the year 1600 raw sugar production in tropical America was the largest industry in the world of that day. The close relationship between cane culture and Negro slavery has been traced by many historians. Cane growing in Louisiana was not successful until 1795, and Australia in 1817 became the last of the large sugar-producing areas to establish the culture.

**Description.**—Sugarcane is a giant perennial grass of the genus *Saccharum*, cultivated in tropical and subtropical regions throughout the world. The plant consists of clumps of solid stalks with regularly spaced joints or nodes, at each of which occurs a single bud or eye. The graceful sword-shaped leaves are similar to those of corn, and the leaf sheath folds around the stem, protecting the bud. Mature canes reach a height of 10 to 20

ft. (3 to 6 m.) and are generally  $1\frac{1}{2}$  to 2 in. ( $3\frac{1}{2}$  to 5 cm.) in diameter, the dimensions varying with local conditions, length of growing period, and the variety of cane. The colour of the cane ranges from almost white, through yellow to deep green, purple, red, or violet. Some varieties have striped or ribbon canes of variegated colours. Until the widespread introduction of seedling canes about 1920, most authorities ascribed all cultivated canes to one species, *Saccharum officinarum*, the so-called native canes or noble canes that had been propagated in their particular areas for many generations. Four other species of "wild" canes are now recognized, which have been crossbred with the native canes to give seedling variety canes now in wide cultivation.

**Seedling Canes.**—Sugarcane comes into flower under the influence of shortening days—in the Northern Hemisphere from September to December, in the Southern Hemisphere from March to June—when the mature plant under favourable climatic conditions produces a "tassel," or "arrow," a handsome plumelike panicle that bears many hundreds of small spikelets with inconspicuous flowerets (see GRASSES: *Andropogoneae*). It was long known that the "arrows" contained minute seeds (so small that nearly 100 would be required to equal the weight of a single grain of wheat), but these were believed to be sterile until about 1888 when J. B. Harrison and J. R. Rovell in Barbados and F. Soltwedel in Java, working independently, announced the growth of cane from seed. This started an intensive search in various parts of the world for new varieties, which has resulted in an immense number of seedlings. The occurrence of disease epidemics among the existing varieties in Java prompted that country to become the first of the cane-growing areas to substitute seedling varieties for the older "noble" strains. New, experimentally bred varieties were developed that far surpassed the old varieties in vigour, disease resistance, and yield of sucrose, and practically all cane-producing countries began to plant the new strains soon after World War I, with the result that many have entirely eliminated the native canes. The Australian cane breeders estimate that 10,000 to 20,000 seedlings and about 10 years' time are required to produce one or two varieties that are successful in commercial culture.

**Diseases and Pests.**—The cultivated sugarcane plant is attacked by numerous diseases and pests that have been transported from one country to another with seed canes. In Java, the Argentine, Puerto Rico, Louisiana, and many other cane areas the highly destructive mosaic disease threatened to destroy the industry entirely, necessitating the prompt introduction of new canes resistant to mosaic. Gummy disease (*Bacterium vasculorum*) has assumed great importance in such widely separated areas as Brazil, Australia, and Mauritius. Other parasitic diseases are leaf scald (*Xanthomonas albilineans*) and Fiji disease (a virus), both preva-

FIG. 1.—(LEFT) FLOWERS OF THE CANE, CALLED TASSELS OR "ARROWS," CONTAIN MINUTE SEEDS; (RIGHT) HARVESTING CANE BY HAND

lent in the Pacific area. Of the insect pests, various moth borers have been especially destructive in the Western Hemisphere, and to some extent in India, Java, and the Philippines. The white grubs of several species of beetles have caused severe damage in Australia and in other regions of the Pacific but are controlled by chemical insecticides. The woolly aphid, froghoppers, and sap-sucking leafhoppers are among other insect pests. Rigid quarantine controls regulating the importation of cane cuttings and other plant carriers into various countries have been effective in preventing the spread of cane diseases and pests.

**Cultivation and Growth.**—Commercial sugarcane is grown from cuttings, never from seed. Pieces of stalks about a foot long, each including several joints or nodes, are planted in a shallow furrow and lightly covered with soil, either by hand or by a mechanical planter. Each bud or "eye" located at the nodes produces a plant consisting of several shoots that grow into a clump or stool of six or eight stalks. Cultivation carried out in the early growth stage is principally for the control of weeds. Chemical fertilizers in relatively large amounts are necessary to maintain yields at economic levels. Loam, clay loam, or muck soils are preferred, sandy loams requiring more moisture and fertilizer. After the cane is cut to the ground at harvest time, new plants, termed ratoons, spring up from the stubble to form a second crop, and in virgin soil this may be repeated for many years without replanting, although one or two years of ratoons are generally the limit. In the United States, north of the Gulf Coast region, annual planting is necessary. Sugarcane grows best in moist hot climates where a period of heavy rainfall is followed by a dry season. These conditions are met in a belt extending from somewhat north of the Tropic of Cancer to slightly south of the Tropic of Capricorn. Where sufficient rainfall is not available, irrigation is resorted to as in Hawaii, Peru, and some parts of Australia. Transpiration is enormous, and irrigation records show crops requiring more than 100 in. (3 m.) per ac. annually for maximum growth. The length of the growing period varies greatly in different countries, Louisiana and other subtropical areas being limited to 7 or 8 months. Cuba and Puerto Rico average 12 months; Hawaiian crops grow for 18, 20, or even 24 months. The plant matures and sucrose increases with the approach of cool or dry weather. The leading producing countries are Cuba, Brazil, India, the United States (Hawaii, Louisiana, and Florida), Australia, the Philippines, and Puerto Rico, but sugarcane is also an important crop in Mexico and throughout Latin America (the Caribbean area and northern South America), Africa (led by South Africa, Mauritius, and Egypt), and Asia (including mainland China, Formosa [Taiwan], Indonesia, Thailand, and Pakistan, in addition to India and the Philippines).

**Harvesting and Transport.**—The greater portion of the world's cane supply is harvested by hand, heavy knives of the machete type being commonly used. The stalk is cut close to the ground, topped just above the uppermost coloured joint, and the remaining leaves stripped off. In some areas the three top joints are reserved for planting. Where labour is scarce, as in Hawaii, the cane while still standing is burned to remove the leaves, and the practice has spread elsewhere because of high costs. Burning does not injure the cane, but deterioration is accelerated and burned cane must be harvested and ground promptly to avoid heavy loss of sucrose. Mechanical harvesting has become more prevalent with increased labour costs, entirely replacing hand-cutting in Hawaii, Louisiana, Florida, and parts of Australia. Mechanical harvesting, however, results in much trash and dirt in the harvested cane, which have an adverse effect on mill performance.

The methods of transport from field to factory vary greatly with local conditions. In many regions, bullock carts collect the cut cane. In the Pacific areas, portable railway tracks are laid in the fields, and many countries where rain is prevalent use motor-trucks with large pneumatic tires. Fluming in mountain streams is practised in some regions, and where waterways are available barges or punts are used for transport. Factory-owned narrow-gauge railways still carry the greater proportion of cane but motor transport has become increasingly important.

The manufacturing season necessarily corresponds to the harvesting period, since cane cannot be stored in hot climates for more than a few days without serious loss of sugar. In the irrigation areas grinding may continue for the greater part of the year. The Louisiana season is limited by frosts to the late fall months, and in the West Indies the period is from January to June. The factories of Indonesia grind from May to November, which corresponds to the season in most areas in the Southern Hemisphere.

## THE SUGAR BEET

The second major source of the world's sugar supply, the sugar beet (*Beta vulgaris*), presents several contrasts to the sugarcane. The beet is grown in temperate or cold climates, in populated and well-developed areas where much of the product is consumed, as compared with the remote tropical regions of cane culture; the sugar is stored in the root instead of in the stalk; seeds are planted annually; and beet culture is a development of comparatively recent time. (For botany, culture, and production, see BEET.)

**History.**—The sugar beet was grown as a garden vegetable and for fodder long before it was valued for its sugar content. Sugar was produced experimentally from beets in Germany in 1747, but the first beet sugar factory was built in Silesia in 1803. Napoleon became interested in 1811 because the English blockade had cut off the raw sugar supply from the West Indies, and under his influence and encouragement 40 factories were established in France. The industry collapsed after his defeat at Waterloo (1815) and did not prosper again until slavery was abolished in the West Indies in 1843. After that, beet sugar production increased so rapidly throughout Europe that by 1880 the tonnage had surpassed that of cane sugar, and from then until World War I the world production of cane and beet was approximately equal.

Beets are grown on nearly all types of soil, with a fairly deep loam, moist but well drained, preferred. They have a wide range in the temperate mid-latitudes, but sugar content develops best in areas with moderate summer temperatures averaging 63°–73° F. (about 17°–23° C) for the three summer months and with well-distributed rainfall during the growing season, unless irrigation is practised. Large quantities are grown in the U.S.S.R. and throughout Europe, especially in France, Western Germany, Italy, the U.K., and Poland. Many other countries have increased sugar-beet production in the second half of the 20th century, including Chile, Uruguay, Iran, Turkey, mainland China, and Japan. In the United States the sugar-beet industry as a successful commercial enterprise began about 1890 with the establishment of factories in California and the Rocky Mountain states, although sporadic attempts had been made in many other states for half a century before that. Beet production in Great Britain is a development of the years following World War I.

**Beet Cultivation and Harvesting.**—Beet seeds are generally planted in the spring, the time depending on the weather and the proposed harvest date. Spacing of rows is from 20 to 28 in. (50 to 70 cm.). After the seedlings attain a height of 4 in., they are thinned and blocked out to allow a space of 8 to 10 in. between plants, which results in about 30,000 plants to the acre. Weed control is by hand hoeing, machine cultivation, and chemical weed killers. Fertilizers are added either to the seedbed or with the seed at the time of planting, or by side-dressing the rows of plants. Irrigation is practised in the far western United States, but in most of Europe and in the Great Lakes area of the U.S. and Canada natural rainfall supplies the needed water. At the end of the growing season, usually with the approach of cold weather, the crop is harvested by machine or by hand by lifting the beets and cutting off the leaves and part of the crowns. The tops are used for cattle feed. The topped beets are collected and carried by motortruck or railway to the factory, where they are processed or stored in large piles. The operations from planting to harvesting and handling the beets, both in transit and in storage, are becoming increasingly mechanized.

**Beet Seed Production.**—The breeding and selection of sugar beets for seed has resulted in the steady improvement of the quality of beets as to both tonnage and sucrose content and is con-

of the great scientific agricultural achievements. The amount of sugar produced per acre has more than tripled since the early days of the industry in Europe. Until World War I practically all beet seeds were produced in Europe, but the United States is now producing its own seed especially suitable for the areas in which they are to be grown. Until 1942 whole beet seeds were planted, but since then the outer corky layers are removed and the seeds screened to reduce the number of seed germs per seedball; this process has developed so that single, or "segmented," seeds can be produced, greatly reducing the costs of thinning.

**Pests and Diseases.**—Insect damage and disease have been almost as destructive as with sugarcane. Beet armyworms, wireworms, cutworms, nematodes, and the larvae of certain beetles occur in the fields at the time of planting. Migrating pests that feed chiefly above ground include the beet leafhopper, adult beetles, grasshoppers, thrips, and webworms. Soil fumigation, crop rotation, weed control, counterattack by parasitic insects, and development of resistant strains, together with spraying and dusting with DDT and other chemical insecticides, are the usual control measures. Fungus diseases of seedlings have caused serious damage but treated seeds and soil treatment with fungicides are effective means of control. Curly top, a virus disease carried by one of the leafhoppers, is controlled by the use of resistant varieties and by control of the leafhopper that carries it. Sugar-beet mosaic is widespread but is not so serious as its counterpart in sugarcane. Various forms of rootrot may cause heavy damage in susceptible areas.

## MANUFACTURE

**History.**—The production of raw cane sugar in the tropics by open-kettle boiling methods changed little through the centuries until the introduction of modern machinery. Sugar refining began as a small-unit operation, depending upon several boilings for purification by recrystallization. In the 17th and 18th centuries literally hundreds of refineries dotted the larger ports of Europe and Great Britain; where the final product was molded into conical shape and hardened by baking.

The invention of the vacuum pan, by E. C. Howard of England about 1813, was an enormous step forward in processing a heat-sensitive material, such as sugar, and vacuum boiling spread fairly rapidly from English refineries to other branches of the industry. All modern sugar boiling, both beet and cane, takes place in vessels similar to the type that Howard introduced. The use of granular bone char (bone black) for the decolorization of refinery "liquors" was another innovation of that period. As an outgrowth of Howard's patent, Norbert Rillieux, a "free man of colour" of Louisiana, built the first multiple-effect evaporator for concentrating cane juice near New Orleans about 1845, resulting in savings in fuel, labour, and sugar that revolutionized the raw-sugar process. The plate-and-frame filter press and the suspended centrifugal were other developments of this general period. All these scientific and technical advances in which the sugar industry pioneered were later adopted or modified for other unrelated industries. The centralization of factories and refineries, so evident in modern practice, began about 1900. In Louisiana in 1880, more than 1,000 small plantation sugar factories produced 135,000 tons of sugar; within 25 years, 200 factories produced more than 400,000 tons. The concentration of the raw-sugar industry in Cuba and Puerto Rico was even more marked during these years.

The delivery of sugarcane and sugar beets to the factory scale for weighing marks the beginning of present-day manufacturing processes. Many steps in the elaboration of cane and beet sugar are similar, but marked differences also exist, especially where beet sugar production is a one-stage process, as in the United States and in many parts of Europe. Raw cane sugar is necessarily manufactured in the cane-producing areas, but refining generally takes place in the great population centres.

### CANE SUGAR MANUFACTURE

**Juice Extraction.**—The milling of cane by crushing and grinding is a highly developed process, the purpose being to rupture the plant cells by pressure to release the sugar-bearing juice. With

few exceptions, the cane is weighed for economic and control purposes, generally in the railway cars, motortrucks, or carts in which it is transported to the mill. In the well-equipped modern factory the cane is unloaded and handled mechanically, traveling on endless conveyors to the crushing equipment.

The high capacities of the mill trains and the tough nature of the material to be ground require machinery of massive construction. Multiple mills arranged in triangular form are universal. Rapidly revolving cane knives, first used in Hawaii, cut the cane into chips to level and compact the bed of cane on the carrier but do not extract any juice. The carrier delivers the cane to a two-roller crusher that expresses about 50% of the juice by breaking and crushing the stalks or chips. Shredders of the hammer mill type shred the cane but extract no juice. In addition to crushers or shredders or both, a modern mill train or "tandem" may consist of from four to seven sets of three-roller combinations, with a capacity of 5,000 tons or more in 24 hours. The individual rolls are peripherally grooved, about 3 ft. in diameter and 5–7 ft. long, and are driven by meshing pinions at the end of the mill shafts. Larger gears connect these pinions with the motive power, which may be steam engines, turbines, or electric motors. Pressures up to 500 tons are applied to the top rollers by hydraulic rams. Two-tandem factories are fairly common, though the largest sugar factories have three tandems. To increase extraction, water or thin juice is sprayed on the blanket of crushed cane between one set of mills and the next. The terms "maceration," "imbibition," or "saturation" are applied interchangeably to this leaching process. Actually only Australia and adjacent countries employ true maceration, where the crushed cane traveling from one mill to the next passes through a bath of hot water or thin juice. Compound maceration, the most efficient system, is illustrated in fig. 2 (fourth mill juice behind second mill, third mill juice behind first mill, water following third mill). The combined juice from the crusher and first mill goes to process for clarification (purification). Continuous diffusers, similar to those used in beet manufacture, show promise in extracting juice from shredded cane.

The "raw juice" going to process contains from 93 to 97% of the sugar originally in the cane, depending on the quality of the cane, the degree of milling, and other related factors. The juice is turbid and dirty, greenish in colour, and acidic (about pH 5). The sucrose content ranges from 10 to 16%, with a purity (percent sucrose in dissolved solids) varying from 80 to 90, mature tropical canes generally yielding richer juice than those in subtropical regions. The nonsucrose solids in the juice consist of reducing sugars (levulose, dextrose); mineral matter, of which potash is the largest constituent; and organic nonsugars, such as nitrogenous bodies, fats, waxes, and pectins or gums. The percentage of these nonsucrose impurities varies with the variety of cane, the growth period, soil conditions, climate, and intensity of milling.

**Bagasse.**—The residue from the milling process, amounting to about 25% of the cane ground, is called bagasse in most cane-grinding countries, but megass in Australia and other British Commonwealth areas. It consists of woody fibre, some unextracted juice, and 40–50% of water. In most factories the bagasse is conveyed directly to the boilers, a ton of wet bagasse having the fuel value of about one barrel of fuel oil or  $\frac{1}{4}$  ton of coal. In 1920 in Louisiana the manufacture of wallboard and insulating board from bagasse was begun, a practice since extended to Australia and Hawaii. Factories in Louisiana also pioneered in the manufacture of plastics and tile from bagasse and in the use of the dried and screened fibres for chicken litter, cattle bedding, and plant mulch. Bagasse fibre had long been recognized as a possible base for paper manufacture, but commercial success was not achieved until 1953. Factories producing bagasse paper now operate in Louisiana, Peru, Brazil, Hawaii, Spain, and the Philippines, while furfural from bagasse is produced in the Dominican Republic. Potential uses include the production of lignin and alpha-cellulose.

**Clarification.**—Purification of the juice, termed clarification or defecation, is primarily designed to remove the maximum quantity of impurities that will result in a clear juice of proper

FIG. 2.—CANE MILLING PLANT

reaction (about neutral, pH 7). Lime and heat have served as clarifying agents for several centuries, and this "simple defecation" is still accepted procedure throughout the world. The addition of lime (about 1½ lb. per ton of cane) neutralizes the organic acids naturally present, after which the juice is heated to the boiling point or higher. The lime salts, mostly calcium phosphate, together with coagulated albumin and some fats, waxes, and gums, form a feathery precipitate that entraps finely suspended matter and part of the colloids. On standing, this defecated juice separates into scums, muds, and clear juice. The hot limed juice stands for an hour or more in open settling tanks and is then decanted, leaving the scums and muds to be filtered.

The heat-and-lime treatment has been modified in numerous ways but without altering the basic process. The earliest system of removing impurities was by skimming the limed juice during boiling in open kettles, but intermittent batch settling replaced this boil-and-skim method many years ago. Since 1920 various types of continuous clarifiers have come into use, the usual form consisting of an enclosed series of shallow trays on which the precipitated materials in the stream of hot juice settle. Revolving arms sweep the muds to a central or peripheral draw-off well (fig. 3). Automatic addition of lime and control of the hydrogen-ion concentration (pH) are customary with continuous clarification systems. A well-clarified juice is a clear dark brown and has the same general composition as the raw juice. Muds and scums are treated by dilution with water, reliming and reheating, followed by filtration through plate-and-frame filter presses, or more generally on rotary-drum vacuum filters (fig. 4). The press juice goes to process, but the press cake is discarded.

**Direct Consumption Sugars.**—The production of white or off-white sugars direct from cane sirup requires more elaborate clarification. Impregnating the juice with sulfur dioxide before liming, formerly a process quite general in Louisiana, Egypt, and South Africa, is on the decline. Carbonatation (carbonation), which involves excess liming and precipitation with carbon dioxide gas as described below for purification of beet juices, is extensively employed in Indonesia (Java) and to some extent in Formosa and other Far Eastern countries to produce a white sugar much superior to any other made directly from cane sirup.

**Evaporation.**—The clarified juice, with a water content between 80 and 90%, goes to the evaporators without further treatment. Multiple-effect vacuum evaporators, in which the latent heat of the vapours is made to do duty several times, consist of a number of cells or bodies arranged in series so that each succeeding body has a higher vacuum, and therefore a lower boiling temperature, than the one preceding it (fig. 5). The heating unit in

each body is a "calandria," or bank of tubes, generally vertical, into the first of which low-pressure steam is admitted. The vapour from the boiling juice passes over to the calandria of the second body, where, because of the higher vacuum, the juice boils at a lower temperature, releasing vapour for boiling the material in the third body and so on, the vapour from the final body going to the condenser. Each pound of steam admitted to the first body evaporates almost a pound of water for each multiple-effect body; i.e., in a quadruple-effect evaporator the steam does nearly four

times the work that it would do in direct boiling. The juice moving continuously from one body to the next becomes successively denser, until in the final body about 75% of the original water has been removed, leaving a sirup containing 60% or more solids of much the same composition as the clarified juice.

**Crystallization.**—Further evaporation of the sirup in single-effect vacuum pans results in the formation of sugar crystals. Vacuum pans having a capacity of 1,000 cu.ft. or more, essentially like a single body of a multiple-effect evaporator, work in batch operations at high vacuum (26 in., 130° F [about 54° C] boiling point). Pan boiling is a highly skilled industrial art that has only recently been simplified in modern installations by the application of control instruments. The pan boiler controls the amount and size of grain by regulating the vacuum, temperature, speed of evaporation, and amount of sirup drawn into the pan. Older style "coil pans" have banks of serpentine copper coils heated by high-pressure steam (50–90 lb. per sq.in. [psi]), but calandria pans using exhaust steam now predominate (fig. 6). The first charge of sirup, about one-third of a panful, is boiled rapidly until supersaturation is reached. At the proper moment, determined either by instruments or from samples drawn by an instrument known as a proofstick, "grain" is made to form either by lowering the temperature or more generally by adding seed crystals of fine sugar. The boiling progresses with further additions of sirup until the finished "strike" or panful is completed. The operator then discharges the massecuite, a dense mixture of crystals and molasses, to the mixer or crystallizer.

**Centrifuging.**—The method of separating the crystals and surrounding mother sirup in all sugar processes is by "purging," or "curing," in suspended centrifugal machines. A revolving cylindrical "basket," hung by a vertical shaft, or "spindle," is driven by belt or direct-connected motor. The basket has perforated metal sides lined with wirecloth and an inner perforated copper sheet. As the basket spins at high velocity, the crystals are retained by the lining, while the molasses passes through to the "curb," or container. After the purging is complete, the sugar may be sprayed with water before discharge to conveyors. The

older centrifugals, which were 40 in. in diameter and revolved at 1,000 rpm, required manual filling and discharging. Newer high-speed machines are 48 in. in diameter and run at 1,400 to 2,000 rpm, usually with complete automatic control, timing, and operation. The cycle from filling to discharge varies from 2 minutes for very high-test massecuites to 15 minutes or more for low grades. Continuous centrifugals came into general use in the 1960s.

**Reboiling Molasses.**—The purged molasses from sirup strikes must be reboiled to reclaim further sugar. Modern cane factories produce only one grade of raw sugar, and, to accomplish this, complex boiling systems have been developed. One system commonly used incorporates the washed grain from the lowest grade, or "C" boiling, into a magma with cane sirup, which is used as a "footing" of seed crystals for the first, or "A" boiling, composed entirely of sirup. The "A" molasses is boiled on a similar footing of "C" sugar to form "B" massecuite, and the mixed "A" and "B" sugars constitute the commercial output of raw sugar. The "C" massecuite is grained on sirup to ensure a clean nucleus for the seed crystals and is completed with "B" molasses. This "C" massecuite goes to a crystallizer, generally a horizontal closed vessel with slowly revolving arms, to agitate the mixture of crystals and molasses during a cooling period of several days. As the massecuite cools, the crystals "grow," reducing the crystallizable sugar in the molasses to a minimum. Modern crystallizers include coils in which water circulates for rapid cooling (fig. 6). Sugar purged from the "C" massecuite serves as seed for high-grade strikes as described, and the "C" molasses is called "blackstrap," the final end product or by-product of the process.

The commercial raw sugar, the raw material for the refining process, is either packed in jute bags or shipped in loose bulk. Practically the entire output of Hawaii, Puerto Rico, Australia, and Louisiana is handled in bulk, and other areas are adopting the practice. The raw sugar contains from 96 to 98% sucrose, 1% or less of reducing sugars, 0.5% ash, less than 1% moisture, and the remainder organic nonsugars.

**By-Products.**—The heavy viscous final molasses, blackstrap, varies in composition with country of origin, maturity of cane, extent of milling, and methods of manufacture. Tropical molasses averages about 35% sucrose, 20% reducing sugar (levulose and dextrose), 10% ash, 15% organic nonsugars, and 20% water. The world output (50 gal. for each ton of raw sugar) is used commercially for cattle feed, for fermentation into alcohol, and, to a lesser degree, for the production of yeast and organic chemicals.

Another by-product of cane milling is cane wax, extracted by organic solvents from the clarification muds. Sugarcane wax has been refined commercially in Louisiana since 1948. Aconitic acid has been commercially extracted from cane molasses in Louisiana. The uses of bagasse, the by-product of milling, were described above.

### BEET SUGAR MANUFACTURE

The beet-sugar process in the United States, and in some other areas as well, is a single-stage operation from the beet to consumer sugar. The manufacturing plants operate only during harvesting, as beet storage for long periods results in heavy losses. Many European factories produce raw beet sugar that is then shipped to separate refineries for reprocessing, thus paralleling the two-stage cane operation. Many of these refineries process imported cane raws in the off-season.

**Juice Extraction.**—The beets taken from storage piles, or directly from trucks or cars, are carried in a stream of water to a washer to remove dirt, after which they are weighed. Sugar is extracted by membrane diffusion, a process in sharp contrast to the crushing and grinding of cane, where the object is to rupture the cells. The beets are sliced into thin V-shaped chips or long narrow strips called cossettes by a series of knives on the inner periphery of a revolving drum that acts somewhat like a kitchen vegetable slicer. Batch diffusion, common in the older factories, consists of a battery of 12 or 14 vertical cylindrical tanks or cells connected in series where the sugar is extracted countercurrently with water. Fresh water is added to that cell in which the cossettes are almost exhausted of sugar, and a fresh batch of cossettes is treated in the last cell with the most concentrated sugar juice. The extracted juice becomes successively stronger as it progresses through the battery, and the sliced beets that have been exhausted of sugar are discharged as pulp when the process is completed. This pulp is then dried and sold as cattle feed. Temperatures are maintained at about 85° C (185° F) by heating the juice as it passes from one cell to the next. After World War II continuous diffusers of various types were widely introduced. In general, they are either of horizontal rotary-drum design or of a chain-drag type that carries the cossettes on wide perforated trays, the travel of

juice and cossettes in the two types being mainly countercurrent, though not entirely so.

The diffusion juice that goes to process is very dark in colour, contains from 10 to 15% sucrose and only traces of reducing sugars (levulose and dextrose), and is higher in mineral matter and nitrogenous bodies than cane juice. The purity (percent of sucrose in dissolved solids) is about 88, and the quantity of juice varies from 120 to 150% of the weight of sliced beets.

**Juice Purification.**—Carbonatation (carbonation) is universal in the beet industry. The active clarifying agents are an excess of  $\text{Ca}(\text{OH})_2$  (lime) and  $\text{CO}_2$  (carbon dioxide gas), which form a precipitate of  $\text{CaCO}_3$  (calcium carbonate) that is readily filtered. The beet process uses much more lime than the cane sugar processes. The high alkalinity (pH 10) has no adverse effect, since beet juices contain practically no reducing sugars.

Carbonatation invariably takes place in two stages. First the heavily limed juice is "gassed" with carbon dioxide. Temperatures of 70° C (158° F) are maintained, and accurate pH control regulates the addition of lime and gas, bringing the pH of the juice to about 10. If the precipitate remains in contact with the juice at lower alkalinities (i.e., if all lime is precipitated in one step), much colour formation and redissolving of impurities will result; hence, double carbonatation is necessary. In batch operations, the entire juice plus precipitate goes to pressure filters; in continuous processes, rotary-drum vacuum filters handle the settled sludge, the juice being decanted. Wash waters from both filtrations serve as makeup for milk of lime or saccharate milk. In the second carbonatation the juice is carbonated again to remove the greater part of the residual lime salts, then passed through pressure filters, followed by treatment with  $\text{SO}_2$  (sulfur dioxide) to reduce the lime salts to a minimum. A final boiling to drive off residual gases leaves a neutral juice (pH 7) of 13 to 14% solids and 90° purity, which goes to the evaporators. Some beet factories further purify the juice with activated vegetable carbons, or with ion-exchange resins, or both.

**Ion-Exchange Resins.**—An innovation since World War II, though not in general use, involves removal of mineral and organic salts by deionization with synthetic resins. The juice must first be cooled to 20° C (68° F) and then passed through a granular cation-exchange resin that replaces cations (calcium, magnesium, sodium, etc.) with hydrogen ions. To prevent inversion of sucrose, the free acid thus formed must be removed promptly by anion-exchange resins that leave the juice almost ash free. Organic nonsugars are also removed so that the purity of the juice improves 6 or 8%. The main disadvantages of this process are heavy capital outlay, the high cost of regenerating the resins, high fuel and water consumption, and appreciable bacterial and inversion losses. Some cane sugar refineries also employ ion-exchange resins to remove mineral salts from liquid sugars, but in general the exchange resins have not attained the promising results predicted for the sugar industry.

**Evaporation, Crystallization, and Finishing.**—The beet process in its final stages closely parallels the steps used in cane sugar manufacture and refining. The clarified thin juice goes to multiple-effect, frequently quintuple-effect, evaporators. Single-effect vacuum pans crystallize the sugar, and separation of crystals and molasses takes place in centrifugal machines. Boiling systems are complex, involving many features common to cane processes. Drying, screening, and packaging are accomplished by standard methods. Beet sugar is generally marketed in the form of table granulated sugar, but production of specialty sugars is increasing. Because of the short manufacturing season, storage in huge silos and packaging throughout the year to meet market requirements are common.

Desugarization of molasses, which is peculiar to the beet industry, is made possible because of the absence of reducing sugars in the juices. The Steffen process involves the addition of finely powdered lime to cold diluted molasses of about 50 purity and 12° Brix (by weight, the percentage of sucrose in a pure sugar solution), with vigorous stirring. The lime combines with the sugar (sucrose) to form insoluble calcium saccharate, which is reclaimed on rotary vacuum filters. On heating the filtrate another

insoluble saccharate appears. The combined cold and hot saccharates in the Steffen process that are slurried in sweet waters make up the "saccharate milk" used as the liming agent for carbonation, the sucrose being released to the juice as the lime is precipitated by carbon dioxide.

**By-Products.**—Beet pulp has always been used as livestock food. Because wet pulp that has been stored in silos or pits develops offensive odour and hence heavy losses, United States practice is to dewater by mechanical pressing, then dry in direct-fired rotary drums. This produces a highly concentrated cattle feed that is frequently mixed with molasses either before or after evaporation. Concentrated Steffen wastes are a source of monosodium glutamate, used as a condiment, and to a lesser extent as a source of betaine and other amino acids. Potash has been recovered from these wastes in war periods. Beet molasses serves as stock feed (normally mixed with beet pulp) and as a base for alcoholic beverages and for yeast manufacture.

### SUGAR REFINING

Sugar refining generally takes place in large plants that have easy access to great market areas. All refined cane sugar in the United States comes from about 20 refineries situated in or near large seaports. British refineries are located in London, Liverpool, and Greenock, Scot. Modern refineries can refine beet or cane raws simultaneously, but in the United States refining as a separate operation is limited to cane sugar. Handling of raw sugar is largely mechanical; bags of sugar are emptied onto conveyor belts soon after delivery from ships, and bulk sugar travels by the same conveyors to storage bins or to process.

**Affination.**—Raw sugar, mixed with heavy sirup in a mixer-type scroll conveyor termed a "mingler," forms a magma that loosens the adhering film of molasses on the raw crystal. The magma (usually warmed) is purged of sirup in conventional centrifugal machines, and the sugar is washed with a spray of warm water before leaving the machine. This yields about 90 lb. of 99-purity sugar per 100 lb. raw melted, and an affination sirup of about 80 purity and 75° Brix. The washed sugar is dissolved in about one-half its weight of hot water, or high-test sweet waters from process, and pumped to the clarification station. Part of the affination sirup goes back to the mingler for mixing with incoming raws, the excess being pumped to process, either for boiling to "remelt sugar" or for clarification and char filtration. Modern affination stations are completely automatic.

**Clarification.**—The clarification (defecation) process prepares the solution of washed sugar, or washed sugar liquor, for char filtration or other decolorization. Three different refinery clarification systems are in use. (1) *Pressure filtration* adds sufficient lime to neutralize acidity (pH 7.4), then heats to 85° C (185° F), adds diatomaceous earth (kieselguhr) as a filter aid (three to six pounds per ton of melt), then passes the treated liquor through leaf-type filters to remove insolubles, some of the colloids and gums, but little or no colour. (2) *The Williamson System*, invented by George B. Williamson in 1918, consists essentially of defecation with phosphoric acid and lime and air-floatation of the precipitated calcium phosphate by impregnation with air bubbles and heating to 95° C (203° F) in troughlike continuous clarifiers. The air bubbles expand, floating the precipitate to the surface to form a blanket of mud. The clear liquor is drawn off without filtration, and the mud blanket removed, all continuously. The phosphate treatment removes 30% of the colour, largely colloidal. All vegetable-carbon plants and most bone char refineries employ phosphate-lime defecation with some modified form of the clarifier. (3) *Carbonation* (carbonation), which is universal in beet sugar work, involves precipitation of an excess of lime with carbon dioxide gas. All cane refineries in Great Britain, Australia, and Canada, and at least one large refinery in the United States, employ carbonation. The calcium carbonate ( $\text{CaCO}_3$ ) formed is easily filtered and washed free of sugar. About 70% of all colour is removed, as well as other impurities, so that a much smaller decolorizing station is required than with other systems.

**Mud Treatment.**—The muds from the pressure filters and

from the Williamson System are diluted and filtered to recover the retained sugar, the high-test sweet waters serving to melt the washed raw sugar. The Williamson filter cake is always discarded, but several large United States refineries regenerate the kieselguhr cake in special furnaces for continued reuse.

**Decolorization.**—The clear yellow to golden brown clarified washed sugar liquor contains about 65% solids (Brix) of 99° purity. Most of the world's large refineries decolorize with bone char; *i.e.*, with granular bone particles carbonized in the absence of air at about 700° C (1,292° F). The liquors percolate through the char in cisterns of 25 tons capacity, 20 ft. deep. The char removes practically all the colouring matter, as well as the ash and organic nonsugars in the liquor, by the physicochemical action known as adsorption. The filter cycle (100 hours or more) consists of: (1) filling the filter with revived char and liquor; (2) filtration proper, first with washed sugar liquor, then with successively lower grades; (3) "sweetening off" with hot water for several hours to obtain "char sweet water"; (4) washing the char to remove the last traces of sugar and soluble matter; (5) draining and discharging the wet char to the dryers and kilns; (6) re-vivification in retort kilns or special furnaces at 600° C (1,112° F) with air excluded; and (7) return to the filters for reuse. With millions of pounds of char, liquors, and water in service, the entire bone char filter station requires continuous control of the quality, temperatures, densities, pH, and colour of the multiple grades of material in process. Liquors flowing from the filter outlet are distributed to proper channels at the "liquor gallery," some for refiltration, others to the vacuum pans for crystallization.

**Activated Carbons.**—The commercial development of decolorization by activated vegetable carbons made from various fibrous wastes (rice hulls, seaweed, peat moss, bagasse, etc.) dates from World War I. About 0.5% of carbon on solids serves to decolorize phosphate-lime defecated washed sugar liquor, generally in a two-stage process in which the carbon is discarded rather than revived. Leaf-type pressure filters remove the carbon, resulting in a much simpler process requiring less equipment, less water, and a smaller capital outlay than required with bone char. Granular carbon, having properties similar to bone char, has been generally adopted as a substitute for the older types of decolorizing agents.

**Crystallization and Finishing.**—The char-filtered or carbon-treated liquors, water-white or nearly so, are crystallized in vacuum pans similar to those used in raw-sugar factories. The pan operator regulates the grain to suit market requirements according to several commercial grades. Centrifugal machines, generally automatic, separate crystals and sirups. A spray of hot water in the centrifugal removes the sirup film from the white sugar crystals, and the washed moist crystals are air dried in large horizontal atmospheric dryers called granulators. Mechanical screening removes lumps and fines, leaving the dry screened product ready for packaging. Sirups from the centrifugals are boiled several times, the darker granulated sirups being returned for refiltration through bone char. Affination sirups are boiled to remelt sugar that goes through the process again with the washed raw sugar. Refinery final molasses, end-product of this complex boiling system, is sold for fermentation and cattle feed, as is cane blackstrap, which it resembles.

**Packaging.**—Since the output of a large refinery includes numerous grades of sugar, packaging depends to a large extent on the type of sugar, and its use for industry or domestic consumption. Commercial grades of sugar range from the large "coffee crystals" popular in England, through several coarse grades used by confectioners and other manufacturers, to the familiar "table granulated" sugar that makes up the greatest portion of the product. Very fine crystals are termed Fruit Sugar, Dessert Sugar, or Superfine. Confectioners' and powdered (icing) sugars are pulverized in hammer mills with 3% cornstarch to prevent caking. Tablet and cube sugars are made from mixtures of crystals and sugar sirups molded into the desired form, then dried or baked. Brown and yellow sugars, styled "soft sugars" by the refiner, have a soft, feathery grain that retains some of the sirup from boiling. Refined sugars are packed in heavy paper bags of 100 lb.

capacity and smaller bags of 10, 5, and 2 lb. each that are enclosed in paper bales of 60 lb. total weight. Cardboard cartons of 5, 2, and 1 lb. capacity are made up into boxes of 25 or 50 lb. The barrel of earlier days, as well as jute and cotton bags, was discontinued during World War II. Shipments of granulated sugar in bulk hopper cars and tank trucks are on the increase. Heavy sucrose and invert sugar sirups for industrial use, generally called liquid sugars, constitute a substantial part of the total refined sugar output. Bulk handling of liquid cane or beet sugar in railroad tank cars or motor tank trucks has become increasingly important.

### ECONOMIC ASPECTS

**Consumption.**—Though sugar did not become a major constituent of food until the 19th century, it is now recognized as an important part of the diet. Besides providing a high energy value per unit of weight (about 1,794 kg-cal. per lb.), it improves the palatability of other foods, as well as serving as a preservative. Though artificial sweetening agents, such as saccharin, are sometimes substituted for sugar, they have no caloric food value. Sugar beets and sugarcane furnish more calories per acre than any other commercial crop, and, when costs are normal, the price of sugar on a caloric basis is among the lowest in foodstuffs.

Per capita consumption of sugar is roughly in direct relation to living standards. The lowest is 3 lb. per yr. in China, whereas Australia, Denmark, and the United Kingdom consume more than 110 lb. per person annually. The U.S. per capita consumption is close to 100 lb. per yr., two-thirds of which is purchased by industrial food processors and one-third for direct consumption in the home.

Leading industrial consumers of sugar include bakers, confectioners, dairies, and manufacturers of alcoholic beverages, soft drinks, paper, plastics, toothpaste, floor wax, toys, and explosives.

**World Supply.**—The production, distribution, and marketing of the world's sugar supply depend on many factors not directly related to supply and demand. Political considerations, such as tariff restrictions, preferential markets, rationing, and government-established quotas, bounties, and taxes, as well as voluntary international agreements to regulate prices, all play a large part. Wars and their aftermaths have affected the industry enormously. The Japanese occupation of the Philippines and Java (Indonesia) during World War II practically destroyed cane production in these two important areas, although both revived rapidly. The beet fields of Europe were the battlegrounds of both World Wars, causing destruction of crops and disruption of production for several years after. On the other hand, Cuba, and to a lesser extent other war-free areas, stepped up production during the war years and the subsequent years of shortage. As an example of these fluctuations, Cuba produced only 2,700,000 short tons in 1940–41, but approached 8,000,000 short tons during the Korean War. The revolution led by Fidel Castro (1959) and his subsequent Communist government, which expropriated and nationalized all sugar plantations and mills (1960), and the flight of much skilled labour from the country, disrupted the industry. In addition, there was extensive hurricane damage, with the result that Cuba's sugar production was reduced to about 4,000,000 short tons in the mid-1960s, yet it remained the world's leading exporter. Cuban production later increased to about 6,000,000 short tons annually.

About 85% of the world's beet sugar, which in the mid-1960s exceeded 29,000,000 short tons, is produced in the countries extending across Europe and Asia from Ireland and Great Britain to the U.S.S.R., including Siberia. In the mid-1960s the U.S.S.R. ranked first with 9,000,000 short tons, followed by France, Western Germany, Italy, and the United Kingdom. Practically all the beet sugar not produced in Europe and northern Asia comes from the United States (Michigan to California) and Canada. Most European countries produce their own sugar supply, except Great Britain, which imports large quantities of cane sugar, mostly from the Commonwealth nations.

In contrast to the somewhat limited area of beet culture, sugarcane grows around the world, generally between latitudes 30° N and 30° S. At least two-thirds of the total cane production (more

than 36,000,000 short tons in the mid-1960s) comes from Cuba, India, Brazil, Australia, the Philippines, Taiwan, (Formosa), Indonesia, Hawaii, Puerto Rico, and the British West Indies. Also of importance as cane producers are Argentina, South Africa, the Dominican Republic, Peru, Egypt, and Mauritius. Cane culture in the continental United States is, for the most part, limited to Louisiana and Florida, but the combined output of beet and cane, including Hawaii and Puerto Rico, exceeded 6,500,000 short tons in the mid-1960s. The United States also imported another 4,500,000 short tons, making it the world's largest sugar consumer.

Possibly 10% of the world's sugar is consumed locally and does not enter into general market channels. India has sometimes produced more cane than Cuba, but the output is largely a low-test sugar that may total several million tons. Latin-American countries and the Philippines also produce these low-grade sugars.

World markets are largely controlled by the International Sugar Agreement, which has been periodically ratified since 1932 by more than 40 nations. Quotas are assigned and adjusted from time to time, depending on the price of sugar. Similar measures have been adopted by the Commonwealth Sugar Agreement. The United States substantially controls domestic prices through the quota system established by the Sugar Act of 1934, under the direction of the Department of Agriculture.

**SUGER** (c. 1081–1151), abbot of Saint-Denis and famous counselor of the French kings Louis VI and Louis VII, epitomizes the type of humbly born administrator increasingly employed by French and English kings from the 12th century onward. Born

ARCHIVES PHOTOGRAPHIQUES

PORTRAIT OF ABBOT SUGER IN STAINED GLASS FROM THE 12TH-CENTURY "LIFE OF THE VIRGIN" WINDOW IN THE ABBEY CHURCH OF SAINT-DENIS

probably at Saint-Denis or at Argenteuil, Suger was vowed to the Abbey of Saint-Denis in 1091, and from 1094 to 1104 was a fellow pupil at the Prieuré de l'Estrée with the future King Louis VI. While continuing his studies, probably at Marmoutiers, Suger was already gaining the reputation of a skilful advocate and at La Charité-sur-Loire in 1107 ably and successfully defended his abbey's privileges against the claims of the bishop of Paris. He was made provost of Berneval in Normandy (1107) and moved to Toury in Beauce (1109). Soon afterward Louis, who had become king in 1108, began to employ Suger on special missions; he was sent to the Lateran Council of 1123 and went on an embassy to Pope Calixtus II in 1122.

While returning from Italy, Suger heard that in his absence he had been elected (1122) abbot of Saint-Denis in succession to Abbot Adam. Some years later, influenced by St. Bernard of Clairvaux, he reformed the abbey, expelling seculars from its precincts and restoring the observance of the strict Benedictine rule (1127). At this period Suger was less at court, attending only on occasions particularly important to the royal family. In 1137 he accompanied the future Louis VII to Aquitaine for the prince's marriage with the heiress Eleanor. A year later Suger was with Louis VII on an expedition to Poitou, but at this period his influence was opposed by the seneschal Ralph of Vermandois and by the queen mother Adelaide. However, with St. Bernard he worked for peace within France, reconciling the king with the

chancellor Algrin (1140) and with Count Thibaut of Blois and Champagne (1144). When Louis set out on the Second Crusade (1147), Suger was appointed regent of France. Ralph of Vermandois and the archbishop of Reims were associated with him, but the main responsibility fell on Suger, whose tenure of office was particularly notable for his brilliant administration of the finances and of the royal demesne. As a result of his excellent management, the increasing wealth and good order of the king's territories made Louis VII, in fact as well as in name, the most powerful prince in France.

Suger's most famous work is his *Vita Ludovici regis* ("The Life of Louis VI"), which is, however, of literary rather than historical interest. He also wrote the first pages of a life of Louis VII. His rebuilding of the abbey church of Saint-Denis was completed in 1145. Reputedly small and with the appearance of a weakling, Suger yet reached his 70th year, dying at Saint-Denis on Jan. 31, 1151.

**SUGGESTION**, in psychology, is a process of human communication that leads the subject to respond uncritically; e.g., in belief or in action. The mode of suggestion, while usually verbal, may be visual or may involve any other sense. The suggestion may be symbolic: a person who is allergic to roses may develop an attack of asthma from looking through a seed catalogue. The tendency to respond to suggestion is not always generalized: a man may be very critical in his business judgments, very suggestible as regards his health.

Most advertisements involve direct suggestion. Subliminal stimulation, the presentation of stimuli too faint or too brief to be perceived, has been offered as an example of indirect suggestion; for example, although the claim has been disputed, popcorn sales were reported to increase by subliminal suggestion via the motion-picture screen.

In prestige suggestion effectiveness depends largely on the credibility of the source. It is often assumed that an authority in nuclear physics, for example, is equally competent in politics or town planning; his prestige in one field may give unwarranted importance to his opinions in an unrelated field (see also *PSYCHOLOGY, SOCIAL: Simple Group Effects*).

Suggestion can stimulate both positive and negative reactions. An invitation for a drink extended to a teetotaler will evoke a negative response. Similarly, statements on racial issues will touch off positive or negative reactions according to the background of the person receiving them (see *ATTITUDE*).

If the surrounding environment provides the stimulus, the process is called heterosuggestion. In autosuggestion the person himself is the source. Such physiological factors as fatigue, malnutrition, and drugs may increase suggestibility but are of relative unimportance in daily life. Brainwashing (q.v.) techniques are examples of the part unusual physiological conditions may play in suggestibility. Such drugs as thiopental sodium and scopolamine increase suggestibility and have been used as aids in inducing hypnotic states (see *HYPNOSIS*).

Psychol.*, vol. 13 (1958); K. G. Stukát, *Suggestibility* (1958); P. Chauchard, *Hypnosis and Suggestion* (1964); M. Teitelbaum, *Hypnosis Induction* (G. H. E.; X.)

**SUHL**, a town of East Germany and capital of Suhl Bezirk (district), German Democratic Republic. The town (pop. [1964] 28,177) is a railway junction 25 mi. (40 km.) S of Gotha. It produces vehicles, machinery, sporting guns, precision measuring instruments, electrical appliances, metalwork, tools, and toys. First mentioned in 1239, it was noted from the 16th century for making firearms.

**SUHL Bezirk** (pop. [1964] 548,949; area 1,497 sq.mi. [3,876 sq.km.]) extends along much of the Thuringian Forest (Thüringer Wald) and the upper Werra Valley. The development of engineering, vehicle-building, and small iron industries was favoured by local potash deposits and iron ore mines. Electrotechnical, glass,

wood, textile, and toy-making enterprises are found in the forest valleys.

**SUI**, a village in the foothills of the Sibi District of West Pakistan, about 60 mi. (97 km.) NE of Jacobabad, which suddenly became of great importance in 1950–51 through the discovery by drilling of immensely rich deposits of natural gas. As Pakistan has only a few oil fields and some poor coal deposits, this discovery changed the whole economic position of the country, providing a cheap source of fuel and power. A pipeline to Karachi was laid down in 1955, a length of 347 mi. (558 km.) being completed in 165 days. Another pipeline reached Multan in 1958 and was subsequently extended to Lahore. The first six wells drilled yielded 70,000,000 cu.ft. (2,000,000 cu.m.) of gas a day. Reserves were estimated to be at least 4,000,000,000,000 cu.ft. (113,000,000,000 cu.m.). The gas is likely to be of particular benefit to the country in the manufacture of chemical fertilizers. (L. D. S.)

**SUICIDE** is the act of voluntary and intentional self-destruction. This definition, however, has at various times and in different places been subject to legal qualification. Thus, in England the term once covered an act of self-destruction committed only while the deceased was of unsound mind; if committed with sound mind, the act was termed *felo-de-se*, a crime which before 1870 could entail forfeiture of the deceased's estate to the crown, and until 1961 any survivor of an attempt was subject to criminal penalty (see *FELO-DE-SE*). In the United States only a few states regard suicide as a criminal act, although it may be criminal to influence or assist in a suicide.

**Religious and Cultural Valuations.**—Suicide has been both condemned and honoured. The Koran severely censures suicide as a graver crime than homicide. The Talmud emphasizes the sacredness of life and condemns suicide as sinful. From the time of the early church, Christianity has opposed self-destruction, though for a time it was debatable whether or not a Christian woman might commit suicide to avoid rape; St. Augustine, however, condemned even this act, and he has been supported by many other Christian writers since. In the Middle Ages, some countries prescribed mutilation of the body and confiscation of the property of a suicide.

The Brahmans of India, however, honoured the person who voluntarily freed himself from his body; hence, the Hindu widow who perished on the funeral pyre of her husband was greatly praised (see *SUTTEE*). The Greeks permitted some convicted criminals to take their own lives, a notable example being Socrates' drinking the hemlock. In Japan, *seppuku* (*hara-kiri*; q.v.), or self-disembowelment, was practised as a ceremonial rite: noblemen were granted the privilege of punishing themselves in this way for wrongdoing; and it was also used to escape the humiliation of failure, to shame one's enemies, to demonstrate loyalty to a recently dead master or emperor, and for other reasons. In World War II, the indoctrination of Japanese soldiers included banzai (suicide charges) and the indoctrination of pilots kamikaze (suicide dive bombing). Spies, and sometimes others in possession of secret information, may be expected to commit suicide if necessary to prevent capture. In Southeast Asia, Buddhist monks and nuns have committed sacrificial suicide by burning themselves alive as a form of social protest, as, for example, in Vietnam.

Few systematic studies have been made of suicide in primitive societies. Anthropologists have claimed that to some peoples, the Zúñi of New Mexico and the Andaman Islanders, for example, the idea of suicide is incomprehensible, and some writers have concluded that suicide rates are very low in primitive societies; other writers have held that rates are much higher in some groups, among the Navaho of North America and the Fiji Islanders, for example, than in most modern societies. Variation in rates of suicide among primitive peoples is probably at least as great as it is among more complex societies. (See also *MORALITY, PRIMITIVE*.)

**Statistics.**—The information available on the numbers and categories of people who commit suicide is not uniformly accurate. Suicide statistics are subject to problems of faulty and incomplete record keeping, attempts at concealment, and differences

in definition. Statistics are completely unavailable for many peoples, and only spotty at best for most. One authority estimated that even the best figures available exclude as much as two-thirds of the suicides committed. On the other hand, most authorities argue that the data available, even though they may be incomplete, are approximate representations of trends. Since the early days of the 19th century, it has been recognized that differences in rates between countries are too great to be explained away in terms of differential accuracy of registration. The suicide rates of some countries in Europe, for example, are more than five times as high as those of others. Ireland has consistently shown one of the lowest rates in Europe, and in the world (less than 3 per 100,000 population). The rates of Denmark, Austria, and Hungary have been among the highest (over 20). The rates of France, West Germany, and Sweden are between 15 and 20; those of the United States and England and Wales between 10 and 12; and of Spain, Italy, and Norway between 5 and 10. Chile ranks with Ireland (less than 3); Uruguay's rate is over 10. Japan (25) is the only country outside Europe to rank consistently among the nations with the highest rates. (See also VITAL STATISTICS.)

**Who Commits Suicide?**—*Age*.—Studies made in Europe and in the United States at widely different periods of time all show that virtually no children below the age of 15 commit suicide, and that the rate for the later teens is low. The rate tends to increase steadily into old age, especially among males. The rate in old age (over 25 per 100,000 population after age 65) is approximately four times the rate in young adulthood.

*Sex and Marital Status*.—The rates for males are consistently higher than those for females, in different countries, at widely different periods of time, and at all ages. The male rate is approximately three to five times the female rate. Women, however, make more unsuccessful attempts at suicide than do men.

Data from Europe and the United States have repeatedly demonstrated that divorced persons and the widowed have much higher suicide rates than married people and those who never married. Having children also appears to be a deterrent to suicide, especially among women.

*Religion and Nationality*.—Roman Catholics characteristically have lower suicide rates than Protestants. Jews tend to have rates as low as or lower than the Catholic rate, but statistics here are less consistent; for example, between 1849 and 1907, the suicide rate among German Jews rose from the lowest to the highest among the three major religious categories in that country.

In general, the predominantly Catholic countries have low suicide rates. The low rates for Catholic Chile, Ireland, Spain, and Italy have been cited under *Statistics*, above; but France has a relatively high rate, while Protestant Norway has a low rate. Most immigrant groups to the United States show higher rates than native-born Americans.

*Race and Occupation*.—Negro Americans have consistently produced suicide rates only about one-third as high as the white Americans' rates; the differences between the males of the two races are usually greater than the differences between the females. Data from England and Wales, where the former occupations of suicides are recorded, indicate that persons in the higher status occupations—professionals, managers, and the like—are more prone to suicide than those of lower status; on the other hand, the lowest status, unskilled workers, shows somewhat higher rates than middle-status categories. Data from the records of U.S. insurance companies reveal the same relationship of occupational status to suicide rates.

**Means of Suicide**.—Means of suicide vary according to such factors as the availability of fatal compounds and weapons, the social customs and fads, and the characteristics of the victim. Various typical and fairly stable differences are found between different societies. In England and Wales, for example, gas (most commonly carbon monoxide) poisoning, other forms of poisoning (mostly by narcotics or "sleeping pills"), hanging, and drowning lead the list. In the United States, on the other hand, shooting is the most common method. A major reason for this appears to be that firearms are much more readily accessible in the United States than in England. It is evident, however, that other factors

also influence the means used: it is generally found, for example, that violent methods of self-destruction are more commonly used by men than by women.

**Conditions Surrounding Suicide**.—*Urban-Rural Residence*.—Almost invariably urban suicide rates have proved higher than rural rates. The notable exceptions have been the rates in the Netherlands, where the high rate among the rural aged causes the rural rates to supersede the urban rates. Within large urban centres suicide rates are highest in the central residential areas bordering on and interspersed among commercial and industrial districts, and decrease out to the periphery. Exceptions to this general trend in the United States are the low rates of those districts that are inhabited predominantly by Negroes, although increasing urbanization of Negroes is raising even the generally low Negro suicide rate.

*Business Conditions*.—Suicide rates tend to rise during times of business depression; the greater portion of the increase is among men in higher status occupations. The peaks of suicide rates have been noticed to occur during the deepest points of economic downturns; the rates begin to drop to their lowest level just prior to the highest points of prosperity.

*War*.—Trend data associated with several wars indicate that wars tend to depress suicide rates even though men in the military services ordinarily have higher suicide rates than civilians, and, of course, more men are in the service during wartime; it seems that, in wartime, suicide rates drop among career military men as well.

*Seasons*.—Data compiled over long periods of time show that suicide rates increase in the late spring and the early summer although there are great variations in this trend from year to year. That this trend cannot be accounted for by weather conditions has been demonstrated in several ways: geographic areas that characteristically enjoy mild weather do not necessarily have higher rates; nor do changes in temperature or humidity themselves correspond regularly with changes in the suicide rate. (M. Gp.)

**Attempted Suicide**.—Statistics on attempted suicide are far more unreliable than those on actual suicide, but rates are undoubtedly many times higher than rates of completed suicide. The distribution of attempted suicide differs in several ways from that of actual suicide. The relative frequency of methods used is different: narcotic poisoning (barbiturates, "sleeping pills") heads the list for attempted suicide in Western European countries. The age and sex ratios are also different. While suicide is nearly everywhere more common among men than women, the reverse is true of attempted suicide. For both sexes, rates of attempted suicide reach a peak between about 25 and 40 years of age, while the peak for suicide is over 50. Thus, most attempted suicides do not seem to represent simply suicides that "accidentally" fail; many appear to represent a "cry for help." Some communities, among them, in the United States, Los Angeles, Boston, Chicago, New York, and Miami, have established suicide prevention centres. These are staffed around the clock by psychiatrists, psychologists, psychiatric social workers, and trained laymen whom the person contemplating suicide can call for help to prevent him from committing the act.

**Causes of Suicide**.—The association of such factors as old age, urban residence, and Protestantism with suicide rates does not necessarily indicate that each is a separate cause of suicide. Theorists have proposed that these associations are evidence for certain underlying causes of suicide, but there is still disagreement about what these underlying causes are.

Sociologist Émile Durkheim, in a major work on suicide (1897), identified two major types of suicide, egoistic and anomic, as characteristic of modern societies, and one type, altruistic, as characteristic of traditional and primitive societies. Egoistic suicide results from lack of integration of the individual into society—a person without close family ties or similar interpersonal connections is not so much deterred from suicide. Thus, according to Durkheim, the suicide rate is lowest among Catholics who are part of a collective religious institution and highest among Protestants, among whom there is greater emphasis on individualism. Anomic suicide results from the failure of normative social standards to

regulate individual behaviour; an individual may take his life when his habitual norms are no longer appropriate to his situation. This type of suicide is most common in periods of economic depression, not because of the sheer poverty involved but because of the resulting state of *anomie*, or normlessness.

English sociologist Peter Sainsbury, emphasizing Durkheim's anomic type of suicide, held that individuals are more prone to suicide when they live in, but apart from, a social group that neither acknowledges nor provides means for satisfying their needs. Where mobility and social isolation are pronounced, community life will be unstable, without order or purpose, and this will be reflected in the suicide rates.

Altruistic suicide results from too much integration of the individual into society so that the individual takes his own life in obedience to the customs of his society, in which suicide in certain situations is regarded either as obligatory or as an honourable act. This type of suicide is presumably most prevalent in preliterate societies and in cultures like Japan's.

In psychological theory, suicide has commonly been related directly to mental disorder, which has often been held to be "the cause" of suicide. However, nothing like a complete correspondence between suicide and accepted forms of mental disorder has ever been demonstrated. The most profitable approach would seem to be to recognize that the cause of suicide and the causes of mental disorder partly overlap, so that a theory of suicide must link up closely with what is known about relevant types of mental disorder. Thus, virtually the only important theoretical approach to suicide in psychology, based on ideas suggested by Freud, links the causes of suicide closely with the causes of depression. According to this theory, depression and suicide can be understood in terms of hostile impulses that, although first directed against others, become turned back against the self. The depressive individual is held to be characterized by an excessively strong and repressive conscience (*superego*), which does not allow him to express his aggressive feelings externally, but which redirects them against the ego. Suicide is seen as an extreme upon a continuum of self-aggression ranging from verbal self-derogation to attempts at self-destruction.

Since the conscience is supposed to be the outer-voice-become-inner of some important figure in the person's life, usually a parent, suicide in this theory takes on the meaning not only of self-destruction but also of murdering an accuser; thus, Karl A. Menninger suggested that every suicide has three elements: (1) the wish to kill, (2) the wish to be killed, and (3) the wish to die. Similarly, Louis I. Dublin proposed that suicide is caused by feelings of fear, inferiority, and death wishes against another with whom the individual identified; guilt is almost invariably present.

Andrew F. Henry and James F. Short are among those theorists who have held that the act of suicide is a manifestation of the general principle that the frustration of any desire is likely to cause aggression. The suicide, according to Henry and Short, turns his aggression inward against himself rather than outward against others (homicide) for reasons associated with his social position and the manner in which he was raised in childhood.

It is clear that no one theory has adequately and completely explained suicide. Hope for a general theory of suicide probably lies in a continuation and development of ideas suggested in the sociological and psychological approaches to the explanation of suicide and embracing a range of factors including individual wishes and attitudes, personal life crises, societal beliefs and practices, and social and economic conditions. In spite of well over a hundred years of research in the field, knowledge of the etiology of suicide is still on a rudimentary level. One reason for this is the obvious difficulty of obtaining adequate and controlled data through which theoretical ideas can be tested.

**SUIR**, a river in the Republic of Ireland that has considerable variety in its 114-mi. (183 km.) course. It rises in the Devil's Bit Mountains and flows south across the lowland of County Tipperary through the town of Thurles and past the ruins of the 12th-century Cistercian abbey of Holycross to the foot of the Knockmealdown Mountains. There, in a wide fertile lowland, it receives an east-flowing tributary, the Tar, bends through an elbow-shaped loop, and flows north around the western edge of the Comeragh Mountains, forming part of the Tipperary-Waterford county boundary. Having now passed through more than half its course, the river enters a long west-east valley guarded on the south by the Comeraghs and consisting of limestone lowlands on the north, except for Slievenamon, another line of hills. The contrast between north and south is well seen at Clonmel (*q.v.*), which has a promenade on the north side of the river giving fine views of the Comeraghs.

In the 1760s the river was made navigable to Clonmel, but the tidal limit is at Carrick-on-Suir (*q.v.*), 15 mi. downstream. There is no water traffic now. Finally the river broadens into an estuary and passes through Waterford (*q.v.*; from Norse times a port and still a major town); a little farther east it is joined by the Barrow and the Nore, all three rivers discharging into the wide estuarine bay called Waterford Harbour.  
(T. W. Fr.)

**SUITE**, in music, from the French *suite de pièces*, a group of self-contained instrumental movements of varying character, usually in the same key. During the 17th and early 18th centuries, the period of its greatest importance, the suite was comprised principally of dance movements. In the 19th and 20th centuries, however, the term was used in a more general sense to cover almost all sets of instrumental pieces, mainly in forms smaller than those of the sonata, including selections for concert performance of music from ballets or from incidental music to plays.

The principle of related dance movements may be said to have its origins in the paired dances of the 14th century; *e.g.*, the saltarello and rotta. The practice of grouping dances of related key but contrasting tempo and metre continued, but by the 16th century the order of the dances had begun to be dictated more by considerations of music than of dance. By the middle of the 17th century French composers had established the principal features of the suite. This essentially French form of the genre was to remain the model for composers of all countries for the following 100 years.

The classical suite of the time of Bach and Handel consists essentially of four principal dance movements—allemande, courante, saraband, and gigue—with one to three lighter movements inserted before the final principal one.

The first movement of the classical suite is the allemande, a staid dance in  $\frac{4}{4}$  time. It has, characteristically, a rich, flowing rhythm, and frequently begins with either one or three short notes before the first full bar.

The second movement is the courante, of which there were two kinds, the French and the Italian. The French courante, beginning, like the allemande, with either one or three short notes before the first full bar, is a dignified dance in an ambiguous rhythm which alternates between  $\frac{3}{2}$  and  $\frac{6}{8}$ . In homage to Couperin, Bach often uses the French courante, but he is happier with the Italian type (the *corrente*), a brilliant, continuously running piece in a quick  $\frac{3}{4}$  or  $\frac{3}{8}$ .

The slow third movement, the saraband, is in triple time, traditionally beginning on the full bar. It has a tendency to the rhythm

Bach's sarabands are among the most simply eloquent and characteristic of his smaller compositions.

Between the saraband and the concluding movement, the gigue, come the lighter subordinate movements, the *galanteries*, from one to three in number. Unlike the other movements of the suite,

the *galanteries* are not always in binary form (see *MUSICAL FORM*). The commonest are: (1) The minuet, a triple time dance of moderate speed; this was often followed by the trio, and the minuet was then repeated. (2) The gavotte, a lively dance in a measured duple time, beginning on the half bar. Like the minuet, the gavotte often takes the form A B A, the second section, called *musette* ("bagpipe"), being on a drone bass. (3) The *bourrée*, not unlike the gavotte, but quicker, and beginning on the last quarter of the bar. (4) The *passepied*, a lively dance in a quick triple time, beginning on the third beat. Less common *galanteries* are: the *loure*, a slow dance; the leisurely *polonaise*; and the *air*, a short, quietly flowing movement which, unlike the others, has no dance associations. The *air* sometimes precedes the *saraband*. The suite usually concludes with the *gigue*, an animated movement in a triplet rhythm ( $\frac{1}{2}$   $\frac{2}{4}$  or  $\frac{3}{8}$ ), lightly fugal in style.

Bach's French suites may be said to mark the end of the classical suite in the French style. His English suites and *partitas* (German suites) are designed on a larger scale and show a tendency toward a more symphonic conception. This is apparent in the scope of the long and characteristic first movement, the prelude. Some of Bach's large-scale suites end with a finale after the *gigue*.

**SUK, JOSEF** (1874–1935), Czech violinist and composer, one of the principal figures of the 20th-century Czech school, was born at Krecovice on Jan. 4, 1874. He studied first with his father and later at the Prague Conservatory, where he graduated in 1891. Later he studied with Antonin Dvorak, whose daughter Ottilie he married in 1898. Earlier, in 1892, he had helped found the Bohemian String Quartet, with which he remained associated until 1922, when he became professor at the Prague Conservatory.

In his symphonies and symphonic poems Suk developed the style of Dvorak and Bedrich Smetana and established his distinctive manner. Many of his works depict the character of Bohemian scenes or are in the form of autobiographical confessions. The *Fantasy* for violin and orchestra (1903) shows his gift for string writing, and his symphonic poem *Zrání* ("Maturity"; 1918) his original harmonic ideas. Between 1914 and 1920 Suk wrote three patriotic works for orchestra: a meditation on the St. Venceslas Chorale; an apotheosis of the Czech heroes in World War I; and a lively march, later provided with words by P. Kricka. These formed a trilogy which became closely associated with the aspirations of the new Czech nation. He died at Benesov, near Prague, on May 29, 1935.

**SUKARNO** (SOEKARNO) (1901– ), first president of Indonesia, was born June 6, 1901, at Surabaya, Java, and graduated in engineering from the Bandung Technical Institute in 1925. By 1928 he had become Indonesia's foremost nationalist leader, advocating noncooperation with the colonial government and independence for Indonesia whose economy was to be organized along socialist lines. He was arrested by Dutch authorities in December 1929 and jailed for two years. His further arrest in July 1933 was followed by a nine-year exile in Flores Island and at Bengkulu in Sumatra. In 1942 he was released by the Japanese, with whom he cooperated in return for concessions providing greater scope in organizing the nationalist movement. Sukarno proclaimed Indonesia's independence on Aug. 17, 1945, becoming its president and a foremost leader in the ensuing struggle for independence.

His synthesis of Marxism, nationalism, and traditional Javanese concepts provided the basis for a national Indonesian ideology—*Marhaenism*. His magnetic personality, which he injected into mass-attended speeches, did much to spread this ideology and his political formulations throughout Indonesia. While sympathetic to much in the program of Indonesian Communists and to the accomplishments of the Chinese Communists, Sukarno opposed proletarian dictatorship and Marxist class analysis. He was a political eclectic insisting upon an ideological synthesis of his own, attuned to the particular conditions existing in Indonesia.

The ineffectiveness of party government during 1950–56 increased Sukarno's long-held reservations concerning the appropriateness of parliamentary democracy for Indonesia. To replace it he advocated a "truly Indonesian" system—"Guided Democracy." This called for temporary representation in government of

FRED MAYER FROM MAGNUM

SUKARNO

influential Islamic political leaders, but following their defeat his position became stronger. In 1960 he dissolved the elected Parliament and replaced it with one appointed by him. He was still obliged to share power with the armed forces, but by 1962 he was clearly the dominant partner. To help ensure his ascendancy he gave the Communist Party (which he regarded as subservient to neither Peking nor Moscow) enough scope for growth to ensure that it would remain a counterweight to the army. Increasingly significant aspects of his policies paralleled those advocated by the Indonesian Communists; while insisting that they be represented in government, however, he refused them key positions.

Sukarno's attitude toward the U.S. and Great Britain was much affected by foreign policy issues, but the most important factor in determining his hostile attitude toward the U.S. was the covert American support given to the anti-Sukarno rebels in 1958. In the 1960s he showed increasing interest in assuming a role as the principal world leader in a struggle against old and "neo" colonial forces. In 1965 he took Indonesia out of the United Nations and with the support of Peking, laid plans for establishment of a rival world organization to be known as CONEFO (Conference of New Emerging Forces). On Oct. 1, 1965, an attempted coup by army elements, largely drawn from central Java and supported by part of the air force and some armed members of the Communist Youth resulted in the killing of six top generals. As a consequence, the Communist Party was outlawed and several hundred thousand adherents massacred. With the elimination of the Communist Party the balance of power was drastically altered in favour of the army, and Sukarno's position was further weakened because it was alleged that he, as well as Communist leaders, was involved in planning the coup. On March 11, 1966, Sukarno was obliged to delegate wide powers to the army commander, General Suharto. There followed a rapid reversal of many of Sukarno's domestic and foreign policies (with Indonesia reentering the United Nations) and an attempt to win Western support for a program of economic recovery. See also INDONESIA, REPUBLIC OF: History.

Kahin, *Nationalism and Revolution in Indonesia* (1952); *Sukarno: an Autobiography*, as Told to Cindy Adams (1965). (G. McT. K.)

**SUKENIK, ELEAZAR LIPA** (1889–1953), Israeli archaeologist who identified the antiquity of the Dead Sea Scrolls (q.v.) and secured the first lot for the Hebrew University of Jerusalem. Born on Aug. 12, 1889, in Russia at Bialystok (now in northeastern Poland), he attended the Hebrew Teachers Seminary and the École Biblique et Archéologique Française at Jerusalem, Ben-Gurion University, and Dropsie College, Philadelphia, Pa. He returned to the Hebrew University as field archaeologist (1926), subsequently becoming (1935) lecturer in and then (1938) professor of the archaeology of Palestine. He was also director of the Museum of Jewish Antiquities. His numerous excavations and investigations led to remarkable discoveries. At Tell Jerishe he found remains of an important Hyksos fortification. Together with L. A. Mayer he published *The Third Wall of Jerusalem* (1930), based on their

excavations, which solved a vexed problem of topography. His Schweich Lectures of 1930 were published as *Ancient Synagogues in Palestine and Greece* (1934). His publication *The Ancient Synagogue of Beth Alpha* (1932) made famous the mosaic pavement he had unearthed and opened a new page in the history of Jewish art. Keen interest in numismatics led to his discovery of the formerly misinterpreted oldest Jewish coins of the Persian period. Sukenik's familiarity with the script of the epitaphs of the Jewish necropolis in Jerusalem, dating from the last century (c. 30 B.C.—A.D. 70) of the Second Temple, enabled him to recognize that the scrolls found in the first Qumran cave in 1947 dated from the same period. His book *The Dead Sea Scrolls of the Hebrew University* (1955) appeared after his death at Jerusalem on Feb. 28, 1953. (N. Av.)

**SUKHOTHAI**, the first independent Thai kingdom. The Thais originally peopled the Yangtze valley, where they founded the empire of Nanchao. Long before the fall of Nanchao, they began to drift southward along the rivers of the Indochinese peninsula, forming small principalities that came under the suzerainty of the Khmers from Cambodia. In 1238 two Thai chieftains from Chiangrai and Chiangmai waged a successful war of independence against the Khmers. One of them assumed the Khmer title of Sri Indradya and proclaimed himself king. He established at Sukhothai the capital city of what was to become a mighty and vigorous, though short-lived, Thai state.

Indradya's third son, Ramkhaeng or Rama the Great (1275–c. 1317), gave Sukhothai its period of greatest glory. He extended his dominion to the Bay of Bengal, Luang Prabang, and down the Malay peninsula as far as Ligor. He maintained relations with the Mongol court in China, receiving emissaries from Kublai Khan and sending numerous tributary missions to Peking. Political disintegration of Sukhothai followed the death of Ramkhaeng, or Phra Ruang, as he is popularly known, and the centre of power shifted southward to the succeeding Thai kingdom of Ayutthaya.

From many peoples and civilizations, the Sukhothai kings drew the elements that went into the making of their own society. Religious missions, objects of Buddhist art, and the basic religious beliefs of Theravada Buddhism came from Ceylon. The pattern of political organization, the Brahmanistic ceremonials associated with kingship, and the alphabet first used to write the Thai language were adopted from Cambodia. Art, sculpture and literature were introduced from India and highly skilled artisans in ceramics were imported from China. The Sukhothai period is known as the golden age in the development of Thai culture.

**SUKHUMI**, seaport and capital of the Abkhaz Autonomous Soviet Socialist Republic in the Georgian S.S.R., U.S.S.R., on the coastal railway about 100 mi. (160 km.) NNW of Batumi. Pop. (1959) 64,730. Its Black Sea location, on the north of a broad, shallow bay with sandy beaches, and subtropical climate have made it one of the most popular of Soviet resorts. There are many sanatoria and holiday camps. Shipping services run to other Black Sea ports. Industries are based on local agricultural products and include fruit canning and wine making, and the production of tobacco, leather goods, and footwear. The town has a botanical garden, a pedagogic institute, and the Institute of Abkhaz Language, Literature, and History. (R. A. F.)

**SUKKOTH**: see JEWISH HOLIDAYS.

**SUKKUR**, a town in the Khairpur division of West Pakistan, and the headquarters of the district of the same name, is situated on the right bank of the Indus River, about 225 mi. (362 km.) NNE of Karachi. Pop. (1961) 103,216. A cantilever bridge connects Sukkur with Rohri on the other bank. Midstream between the two towns lies the island fortress of Bukkur. The newer part of Sukkur is partly built on a rocky site connected with a low limestone hill. In the old town there are ruins of many tombs and mosques. On the western side, overlooking the river, is the lofty minaret of Mir Masum Shah, erected about 1607. Other antiquities include the white tomb of Adam Shah, the first of the Kalhoras, and the blue tomb of Shah Khairuddin, the founder of a spiritual order. Sukkur also possesses a degree college. The town is an important trade and industrial centre, with cotton and

silk textile and hosiery mills, and biscuit, oil, flour, and other factories. It is also noted for cotton handloom weaving. The Sukkur industrial trading estate was developed in the 1950s to provide facilities for factories using local materials, such as wool, oilseeds, and hides and skins.

**SUKKUR DISTRICT** has an area of 5,531 sq.mi. (14,325 sq.km.). Pop. (1961) 836,867. It consists of an alluvial plain broken only at Sukkur and Rohri by limestone hills that provide firm banks for the Indus. The eastern section of the district, known as Registan, forms a part of the Thal Desert and is covered with sand dunes. The principal crops are rice, wheat, gram, and millets. Earthenware, leather-, and metalware, cotton cloth, and tussah silk are manufactured, also pipe bowls, snuffboxes, and scissors. Sukkur is the site of the Lloyd Barrage, completed in 1932. The barrage, about one mile long, crosses the Indus and feeds four main canals on the left bank and three on the right. The canals cover a cultivable area of 5,400,000 ac. (2,185,000 ha.) and a gross area of 8,300,000 ac. (3,359,000 ha.). Numerous ferries cross the Indus at different places, the exact positions of the crossings varying with the changes in the course of the river. Rohri and Shikarpur are the only other important towns. At Shikarpur (pop. [1961] 53,910) brassware and locks are manufactured. The town also has a degree college affiliated with Sind University. Rohri (pop. [1961] 19,072) is an important railway junction and has a cement factory.

(K. S. Ad.)

**SUKUMA** (BASUKUMA, WASUKUMA), a Bantu people who inhabit the area southwest of Lake Victoria between Smith Sound and the Serengeti Plain in Tanganyika, Tanzania. Numbering about 1,000,000 in the 1960s, and traditionally divided into many small chiefdoms, they combined as a political federation that operated from 1964 as a unit under the government of Tanzania. Linguistically they are closest to their southern neighbours the Nyamwezi (*q.v.*), but some Sukuma chiefs claim descent from the Hima people to the northwest (see NKOLE). Traditional Sukuma economy is based on cattle, millet, and sorghum; cotton was added as a cash crop in recent times.

Historically the Sukuma chief (*Ntemi*) was advised by a group of hereditary councilors and ruled through hereditary village headmen. Adult males were divided into two clubs or lodges: one specialized in divination (*q.v.*) and advised the headmen; the other was in charge of land administration and communal labour. Numerous other societies were devoted to mutual aid in cultivation. Inheritance of property and succession to office are usually patrilineal; however, the office of chief passes to one of his sisters' sons, while the children of a woman married without bridewealth (*q.v.*) inherit from her family instead of from their father's. Traditional religion mainly involved communicating with and propitiating ancestral spirits.

(L. A. Fs.)

**SULAIMAN RANGE**, a range of mountains in West Pakistan, stretching for about 250 mi. (400 km.) from the Gumal Pass (which gives access from northern Baluchistan to Derâ Ismail Khan and the upper Indus) to the Marri and Bugti tribal country north of Jacobabad and the lower Indus. The height of the range gradually decreases toward the south. In the northern part, pale, marine coral limestone rests on Cretaceous Sandstone, while, in the south, sandstone, clays, and marble predominate. Edible pines abound in the higher northern part and olives in the centre, but vegetation is scarce in the south. The northern part is transversely cut by very narrow gorges that provide means of communication across the range, the principal routes being through the Ghat, Zao, Chuharkhel Dhana, and Sakhi Sarwar passes. In the southern part, about 60 mi. (97 km.) from Dera Ghazi Khan lies the hill station of Fort Munro (6,303 ft. [1,921 m.]). The highest point of the range is the twin peak known as Takht-i-Sulaiman, or Solomon's Throne (the higher one being 11,290 ft. [3,441 m.]), at the northern end, which legend connects with Solomon's visit to Hindustan. It has a *ziarat*, or shrine, which, though difficult of approach, is visited annually by many pilgrims. On both sides of the Takht-i-Sulaiman dwell the Shirani Pathans, those on the eastern slope being known as the Largha and those on the western as the Bargha. (C. C. D.; K. S. Ad.)

**SULA ISLANDS**, a chain of islands east of Celebes (Sulawesi), Indonesia, physically an extension of the eastern peninsula of that island, and administratively forming part of the Maluku Utara (North Moluccas) *kabupaten* (regency). The population (1957 est.) was 30,779. There are three large islands, Taliabu, Mangole, and Sanana (also known as Sula Besi), and several smaller ones. Taliabu and Mangole, separated by the narrow Tjapalulu Strait, extend (with Lifamatola) about 135 mi. (217 km.) east and west. Both are narrow, mountainous, thickly forested, and thinly populated. Taliabu, the largest in area and little known, is said to contain hot springs and mountains 3,000–4,000 ft. (900–1,200 m.) high. Mangole, much narrower than Taliabu, has Mt. Buja in the west. Sanana, the smallest of the three, is well populated and cultivated.

The naturalist A. R. Wallace considered that the approximation between the birds of the Sula Islands and those of Buru Island, in the Moluccas, indicated that there had once been a land bridge between them. The babirusa and crested baboon of Buru are also found in the Sulas. The islands produce timber for shipbuilding, and the inhabitants are good navigators. Damar is collected in the forests; rice, maize, tobacco, and sugarcane are grown on Sanana, where cultivation is far superior to that of the other islands. The sago palm is common, forming the staple food on Taliabu and Mangole. Coal of inferior quality is found on Sanana, and the people weave sarongs and plait mats.

The people of the Sulas resemble the inhabitants of Buru and Ceram (*q.v.*) and may be of Malayo-Polynesian stock from eastern Celebes. Most of them are pagan, but Muslim elements are increasing. The town of Sanana on the northeastern coast of Sanana Island is the chief town and the residence of the local administrator of the islands. The town, formerly the haunt of pirates, has a good roadstead and is a port of call for vessels.

The Banggai or Peleng islands, off the western end of Taliabu, are little known; Peleng itself is mountainous and well forested, with bays affording anchorage but also with reefs. They supply trepang and turtle. The people, who are also either pagan or Muslim, live along the coast.

The Sula and Banggai isles once formed part of the territory of the sultan of Ternate and came under Dutch influence when the Dutch took over the sultan's possessions in 1683. The Sula Islands were occupied by Japan in World War II.

(E. E. L.; J. O. M. B.)

**SULAYMANIYAH**, a town and administrative centre of Sulaymaniyah *liwa'*, Iraq, lies about 30 mi. (48 km.) W of the Iraqi-Iranian frontier in a fertile basin situated between two mountain ranges, the Baranand Dag and Azmar Dag, and drained by the Av-i Tanjero, one of the main headstreams forming the Diyala River. Sulaymaniyah itself lies mostly on the lower slopes of the Azmar Dag and is surrounded on all sides except the southeastern by bare and wild hill country that culminates in the Pir-i Makurun (8,600 ft. [2,621 m.]), 20 mi. NE. Climatic conditions are relatively severe, with cold winters (snow on 50–60 days) and hot but variable summers. Pop. (1961 est.) 42,000.

Sulaymaniyah is somewhat unusual in Iraq, having an extensive open square, and many houses, generally flat roofed, standing in walled compounds or gardens. It is a market centre for cereals (wheat, barley; and some rice) grown in the Tanjero valley and for the gum and pastoral products (wool, skins, and dairy produce) of the mountain zone. Lying on the trade route from Baghdad to Tabriz, it has an important merchant community. The inhabitants are mainly Kurds (*q.v.*), and the town is a centre of Kurdish nationalism.

The whole region was for long in dispute between Ottoman Turkey and Persia; the present town was established by a local ruler in 1781 and named after the contemporary Ottoman pasha of Baghdad.

**SULAYMANIYAH LIWA'** comprises not only the headstream zone of the Diyala River but part of another basin, that of the Lesser Zab. Area 4,630 sq.mi. (11,992 sq.km.). Pop. (1965) 408,220.

(W. B. Fr.)

**SULEIMAN I**, known to the Turks as **KANUNI**, "the Lawgiver," and to the Christian world as **THE MAGNIFICENT** (1494/

BY COURTESY OF THE ALBERTINA, VIENNA

SULEIMAN I

Engraved portrait from life by a Danish artist, Melchior Lorichs, who visited Constantinople in 1559

1495–1566), sultan of the Ottoman Empire from 1520 to 1566, whose reign witnessed the unfolding of all that was most characteristic and brilliant in Ottoman civilization, was the only son of Sultan Selim I. He became Sanjak Beg of Kaffa in the Crimea during the reign of his grandfather Bayazid II and Sanjak Beg at Manisa in western Asia Minor in the reign of Selim I.

Suleiman succeeded his father as sultan in September 1520. Belgrade fell to him in 1521 and Rhodes, long under the rule of the Knights of St. John, in 1522. At Mohács, in August 1526, Suleiman broke the military strength of Hungary, the Hungarian king, Louis II, losing his life in the battle. The vacant throne of Hungary was now

claimed by Ferdinand, the Habsburg archduke of Austria, and by John Zápolya, who was voivode of Transylvania and the candidate of the "native" party opposed to the prospect of Habsburg rule. Suleiman agreed to recognize Zápolya as a vassal king of Hungary, and in 1529, hoping to remove at one blow all further intervention by Austria, he laid siege to Vienna. Difficulties of time and distance, of bad weather and lack of supplies, no less than the resistance of the Christians, forced the sultan to raise the siege. The campaign was successful, however, in a more immediate sense, for Zápolya was to rule thereafter over most of Hungary until his death in 1540. A second great campaign in 1532, notable for the brilliant Christian defense of Güns, ended as a mere foray into Austrian border territories. The sultan, preoccupied with affairs in the East and convinced that Austria was not to be overcome at one stroke, granted a truce to the archduke Ferdinand in 1533.

The death of Zápolya in 1540 and the prompt advance of Austrian forces once more into central Hungary drove Suleiman to modify profoundly the solution that he had imposed in the time of Zápolya. The great Ottoman campaigns of 1541 and 1543 led to the emergence of three distinct Hungaries—Habsburg Hungary in the extreme north and west; Ottoman Hungary along the middle Danube, a region under direct and permanent military occupation by the Ottomans and with its main centre at Buda; and Transylvania, a vassal state dependent on the Porte and in the hands of John Sigismund, the son of Zápolya. Between 1543 and 1562 the war in Hungary continued, broken by truces and with few notable changes on either side; the most important was the Ottoman capture of Temesvár (Timișoara) in 1552. After long negotiations a peace recognizing the *status quo* in Hungary was signed in 1561.

Suleiman waged three major campaigns against Persia. The first (1534–35) gave the Ottomans control over the region of Erzurum in eastern Asia Minor and also witnessed the Ottoman conquest of Iraq, a success that rounded off the achievements of Selim I. The second campaign in 1548–49 brought much of the area around Lake Van under Ottoman rule, but the third (1554–55) served rather as a warning to the Ottomans of the difficulty of subduing the Safavid state in Persia. The first formal peace between the Ottomans and the Safavids was signed in 1555, but it offered no clear solution to the problems confronting the Ottoman sultan on his eastern frontier.

The naval strength of the Ottomans became formidable in the reign of Sultan Suleiman. Khair ed-Din, known in the West as Barbarossa (*q.v.*), became *kapudan* (high admiral) of the Ottoman fleet and won off Preveza a sea fight (1538) against the combined fleets of Venice and Spain, which gave to the Ottomans the naval initiative in the Mediterranean until the Battle of Lepanto in 1571. Tripoli in North Africa fell to the Ottomans in 1551. A strong Spanish expedition against Tripoli was crushed at Djerba in 1560, but the Ottomans failed to capture Malta from the Knights

St. John in 1565. Ottoman naval power was felt at this time even as far afield as India, where a fleet sent out from Egypt made an unsuccessful attempt in 1538 to take Diu from the Portuguese.

The later years of Suleiman were troubled by conflict between his sons. Mustafa had become by 1553 a focus of disaffection in Asia Minor and was executed in that year on the order of the sultan. There followed during 1559–61 a conflict between the princes Selim and Bayazid over the succession to the throne, which ended with the defeat and execution of Bayazid. Suleiman himself died during the night of Sept. 5/6, 1566, while he was besieging the fortress of Szigetvár in Hungary.

The great figures who surrounded the sultan contributed much, no doubt, to the splendour of the reign: men like Ibrahim Pasha, Rustem Pasha, and Mehmed Sokollu Pasha in the field of statecraft; like Baki, the prince of Ottoman poets, and Mimar Sinan, the most renowned of Ottoman architects; or like Abu Su'ud in the field of law. Suleiman himself was, to his subjects, the "Law-giver," due to the fact that his long reign saw a sustained effort to adjust the complex structure of the Ottoman state to the circumstances of a new age. To his contemporaries in Europe Suleiman was "il magnifico," "the magnificent sultan." It was the Venetian Andre Navagero who paid him the rarest of compliments when he wrote that Suleiman, provided he were well informed, did injustice to no one. See also **TURKEY: History**; and references under "Suleiman I" in the Index.

See R. B. Merriman, *Suleiman the Magnificent* (1944); *The New Cambridge Modern History*, ch. xvii (1958). (V. J. P.)

**SULEIMAN II** (1642–1691), a sultan of the Ottoman Empire, was born in Istanbul on April 15, 1642, and succeeded his brother Mohammed IV in 1687. An enforced retirement of 46 years qualified him for the cloister rather than for the throne, and his first feeling when notified of his accession was one of terror of his brother's vengeance. Nor were the circumstances of a nature to reassure him. Immediately following his elevation to the throne occurred one of the most violent revolts of the janizaries, which ended in the murder of the grand vizier and the brutal mutilation of his family, with massacre and pillage throughout Istanbul. Yet Suleiman, in spite of his poor physique and unsuitable upbringing, possessed a martial spirit, and he twice took the field with his troops. The war with Austria (begun before Suleiman's accession) was for Turkey a succession of disasters, but, fortunately for the Ottoman Empire, a third great Koprulu (Mustafa) arose at this time and reestablished order in the sorely tried state. (See **KOPRULU**.) In the reforms that followed, which greatly improved the situation of the Christian subjects of the Porte, Suleiman is at least to be given the credit of having allowed Mustafa Koprulu a free hand. With an improved administration, Turkey's fortunes in the Austrian war began to revive, and the reconquest of Belgrade late in 1690 was the last important event before Suleiman's death at Edirne on June 23, 1691. See also **TURKEY: History**.

(G. L. L.; X.)

**SULEYMAN CHELEBI** (d. 1422), Turkish poet, was the author of one work only, the great religious poem *Mevlid*. The son of a vizier, he was born in Bursa and became imam of the great mosque there. The *Mevlid* tells the story of the Prophet's life and death, his miracles, and his heavenly journey. Though written in simple language it is inspired with religious fervour and is often recited at religious ceremonies, particularly funerals. Suleyman Chelebi seems to have made use of the legends on Mohammed which spread through Islamic literature. Further, a few verses of Ashik Pasha's *Garibname* (1329) are reproduced in the *Mevlid*, and the passage on the birth of the Prophet is closely inspired by a corresponding passage in Mustafa Darir's verse and prose translation of Ibn Ishaq's biography.

See F. Lyman MacCallum, *The Mevlidi Sherif*, with Eng. trans. (1943) and edition by Ahmed Atesh (1954). (F. I.)

**SULFA DRUGS**: see **SULFONAMIDES**.

**SULFONAMIDES**, a group of chemicals used chiefly in combating infectious disease. Initially, the "sulfa" drugs were produced for treating bacterial infections, but they have come to be used also in treating histoplasmosis and South American blastomycosis (fungus-caused diseases) and diabetes mellitus (a meta-

bolic disorder), and as antihypertensive and diuretic agents.

The sulfonamides have as their basic structure *p*-aminobenzene-sulfonamide. From the parent substance, designated sulfanilamide, various related compounds are made, usually by substituting or adding various groups to the sulfone radical (see below).

**History**.—In 1932 Gerhard Domagk (*q.v.*) reported to the chemists Fritz Mietzsch and Joseph Klarer that the compound Prontosil, which they had prepared for study, had a curative action in many experimental streptococcal infections. Several years later, Domagk described experiments which demonstrated that Prontosil was a dye of low toxicity, and that when it was administered to mice infected with streptococci, it prevented death. This dye was also effective in controlling staphylococcal infections in rabbits, but it was ineffective in pneumococcal and other experimental infections. These studies by Domagk excited interest in chemotherapy in France, England, and the United States. Within a relatively short period of time it was demonstrated that Prontosil was not only effective in experimental infections in animals but that it also had a powerful effect upon the course of streptococcal diseases in man, including meningitis and puerperal sepsis. It remained for French investigators to point out that the azo dye Prontosil opened up in the tissues, and that it was broken at the azo linkage to *p*-aminobenzenesulfonamide. Moreover, they suggested and later proved that the active principle in Prontosil was sulfanilamide.

In the United States the first important observations were made by P. H. Long and E. A. Bliss in Baltimore; they were soon followed by those of others. Experimental and clinical observations on patients were placed on a sound basis by E. K. Marshall and his associates through the development of chemical methods for determining the amount and distribution of these drugs in the body after they are given by mouth or injected into the bloodstream. To Marshall and his colleagues belongs the credit for placing bacterial chemotherapy on a sound and rational basis, since clinicians, by using their methods of chemical analysis and knowing the pharmacology of these substances, could use objective methods in following patients undergoing such treatment.

As new sulfonamides have been synthesized and applied in the study of infections and other diseases in man and animals, more effective and less toxic agents have been discovered. Also, some compounds have been developed that exert their main effect locally in the gastrointestinal tract and are not absorbed. Others are absorbed slowly or excreted slowly, so that they are longer acting.

The sulfonamides have come to be used most widely in the treatment of urinary tract infections, for the treatment and prevention of meningococcal meningitis, for bacillary dysentery, for pneumococcal pneumonia, and for prophylaxis of streptococcal infections. They are combined with antibiotics to broaden the spectrum of activity and to delay the emergence of resistant bacteria, especially in *Hemophilus influenzae* and *Pseudomonas aeruginosa* infections of the meninges.

Scarcely a year goes by that new sulfonamides are not synthesized and tested. A large number of drugs have been tested and found to be effective, among them sulfapyridine, sulfathiazol, sulfadiazine, sulfapyrazine, sulfamerazine, sulfaguanidine, sulfasuxadine, sulfisoxazole, sulfamethoxypyridazine, sulfachloropyridazine, and sulfisomidine. The most widely used of all these sulfonamides are sulfadiazine, sulfisoxazole, and sulfasuxadine. (C. S. Kr.)

**Mode of Action**.—The sulfonamides inhibit the growth of susceptible microorganisms by preventing the formation of folic acid, a member of the B-group of vitamins present in all living cells and functioning as a coenzyme in the synthesis of many important constituents of protoplasm. Most bacteria make their own folic acid from simpler starting materials, while man and other higher animals must have folic acid supplied in the diet. Thus, the sulfonamides can inhibit the growth of invading microorganisms without harming the host, since the enzymatic reaction these drugs inhibit does not take place in the host.

T. C. Stamp provided the first clue to the mode of action of the sulfonamides by discovering in 1939 an unknown substance in yeast that antagonized the antibacterial effect of sulfanilamide.

A year later, D. D. Woods identified this substance as *p*-amino-

benzoic acid (see formula A), which closely resembles sulfanilamide (see formula B) in structure. Woods's explanation of how *p*-aminobenzoic acid reverses the inhibitory effect of sulfonamides had far-reaching effects in chemotherapy, nutrition, and enzymology. Although *p*-aminobenzoic acid had never before been found in living cells, Woods postulated that it was essential for the multiplication of the bacterial cell and that the sulfonamides inhibited enzymes involved in its utilization by virtue of their close structural resemblance to *p*-aminobenzoic acid.

His prediction was soon verified by the discovery of *p*-aminobenzoic acid as a growth factor for several microorganisms and as a portion of the folic acid molecule. Thus, it is apparent that the sulfonamides act by being absorbed to folic acid-synthesizing enzymes in place of *p*-aminobenzoic acid and thus preventing folic acid formation.

(J. W. MR.)

**Sulfonamide Resistance.**—Bacteria become increasingly resistant to the sulfonamides after exposure to them. These agents are principally bacteriostatic, *i.e.*, they inhibit the growth and multiplication of bacteria; and with the body's defense mechanism they act to control infection. When the action of the sulfonamides is interfered with by pus or chemicals such as procaine or para-aminobenzoic, then strains of bacteria that are resistant to their action emerge and survive. Also, the bacteriostatic action of sulfonamides is diminished by acetylation, a process in which an acetyl group is substituted for one of the hydrogens of the para-amino group of the sulfonamide molecule.

The problem of sulfonamide resistance is of importance in the management of infections. When sulfadiazine was used in mass prophylaxis during World War II in an attempt to control the spread of hemolytic streptococcal infections and thus prevent tonsillitis, scarlet fever, and their consequences (rheumatic fever and acute nephritis), it was found that resistant strains soon appeared in the population being treated. From patients harbouring sulfonamide-resistant strains the organisms spread to others in the community; thus new outbreaks of sulfonamide-resistant streptococcal disease were observed.

**Triple Sulfonamides.**—In an attempt to increase the solubility of sulfonamides and decrease their toxicity and their capacity to produce hypersensitivity, sulfonamide mixtures have been advocated and widely used. O. Lehr pointed out that several sulfonamides can be dissolved simultaneously in the same medium almost to the full extent of their saturation level without the occurrence of precipitation. Moreover, he showed that mixtures of partial dosages of several sulfonamides showed substantially less tendency toward the development of renal obstruction by intratubular deposition of crystals than do any of the single components of the mixture in equal total dosage.

Highly soluble sulfonamides, or sulfonamide mixtures that are more soluble than individual members of the mixture, have been found to be effective in the prevention and treatment of renal complications.

**Toxic Effects.**—All the sulfonamides are capable of causing drug intoxication, and some patients are hypersensitive to them. It is advisable that these drugs be taken only under the direction of a physician and for no longer a period than necessary. The commonest side effects are nausea, vomiting, and mental confusion. The signs of hypersensitivity are fever and skin eruptions. Other signs of intoxication are anemia resulting from destruction of red blood cells and leukopenia from destruction of white blood corpuscles. Irritation of the kidneys and obstruction of the free flow of urine are undesirable reactions that can be avoided by using the triple sulfonamides and keeping the reaction of the urine alkaline or by using the highly soluble bacterocyclic derivatives of sulfanilamide and maintaining urinary output at a quart to a quart and a half a day.

All the signs of drug intoxication should be watched for in patients receiving sulfonamide drugs, and if any signs occur the drug should be discontinued at once.

See CHEMOTHERAPY. See also references under "Sulfonamides" in the Index.

S. K.).

**SULFONIC ACIDS**, organic acids containing sulfur and having the general formula  $\text{RSO}_3\text{H}$ , where R is either an alkyl (*e.g.*, methyl) or an aryl (*e.g.*, phenyl) radical.

**Aromatic Sulfonic Acids.**—The acids of this more important group are obtained generally by treating aromatic compounds with concentrated sulfuric acid, the process being called sulfonation. Such operations are frequently conducted on a manufacturing scale as in the preparation of the sulfonic acids of benzene (*q.v.*), naphthalene (*q.v.*), and anthraquinone (*q.v.*). The sodium salt of benzenesulfonic acid is of importance since on fusion with sodium hydroxide it yields sodium phenoxide, from which phenol is liberated by a strong acid. During World War I large quantities of synthetic phenol were made by this process in order to eke out the supply of coal-tar phenol, which was then insufficient for the wholesale production of the explosive, picric acid (*q.v.*). From then, the process retained its importance in consequence of the large demand for phenol in the manufacture of synthetic resins and plastics (*q.v.*). Benzenedisulfonic acid, made from oleum (fuming sulfuric acid) and benzene, yields by alkali fusion the important dye intermediate, resorcinol.

The sulfonic acids of naphthalene are manufactured on an extensive scale. Anthraquinone, the oxidation product of anthracene (*q.v.*), when sulfonated with oleum at high temperatures yields anthraquinone- $\beta$ -sulfonic acid, the sodium salt of which ("sulfon salt") is an important intermediate used in the manufacture of alizarin (*q.v.*) and the indanthrene vat dyes. Sulfonation of anthraquinone is facilitated by a mercuric sulfate catalyst. Sulfonation may be effected also by chlorosulfonic acid where the sulfonfyl chlorides are formed. (See SACCHARIN.)

Sulfonic acids of aromatic hydrocarbons are very soluble in water, and in the crystalline form are extremely hygroscopic. With phosphorus pentachloride they yield sulfonyl chlorides, which are reducible to thiophenols.

Sulfanilic acid, a sulfonic acid of aniline, is sparingly soluble in cold water and is to be regarded as an internal salt

Its amide is important as the simplest member of the medicinally important sulfonamides (*q.v.*). Sulfanilic acid and the similar naphthylamine sulfonic acids are important dye intermediates.

**Aliphatic Sulfonic Acids.**—These are less important than those of the aromatic series. They are obtained generally (1) by oxidation of mercaptans, alkyl disulfides, alkyl thiocyanates or alkyl sulfonic acids; (2) by the interaction of alkyl iodides and metallic sulfites; (3) by the action of sulfonyl chloride  $\text{SO}_2\text{Cl}_2$  upon a saturated hydrocarbon in the presence of light and of a catalyst such as pyridine; (4) by the action of sodium bisulfate upon an olefin in the presence of oxygen or other oxidizing agent. They are either viscous liquids or crystalline solids, convertible into sulfonyl chlorides by phosphorus pentachloride.

**Hydroaromatic Sulfonic Acids.**—Camphor yields a characteristic sulfonic acid on sulfonation with sulfuric acid in acetic anhydride. The optically active camphor sulfonic acids from dextro- and levo-modifications of camphor have been very useful in the resolution of racemoid bases. See STEREOCHEMISTRY.

(G. T. M.; X)

**SULFONMETHANE GROUP**, a group of hypnotic drugs formerly popular but now seldom used. These disulfone com-

pounds were introduced into therapeutics between 1884 and 1888 by Eugen Baumann and Alfred Kast. Sulfonmethane (Sulfonal) is slowly absorbed from the intestinal tract. Depression after awakening is common and may be severe. Because the drug is slowly excreted, cumulation may occur during continuous administration, producing toxic effects. Death from overdosage is a result of failure of respiration and circulation. Chronic poisoning causes mental and gastrointestinal symptoms and urinary changes. Other toxic manifestations may appear in the skin, liver, and kidneys.

Sulfonethylmethane (Trional) and sulfondiethylmethane (Tetronal) are other members of the group. Trional is absorbed more rapidly than Sulfonal, Tetronal more slowly. (A. E. SH.; X.)

**SULFUR**, a nonmetallic chemical element used in making sulfur dioxide, sulfuric acid, carbon disulfide, and other sulfur compounds, was discovered in prehistoric times. Its name is derived from the Latin word for brimstone (burning stone), and ignited sulfur is mentioned in the earlier records of many countries as having been used for religious ceremonies, for purifying (fumigating) buildings, and for bleaching cloth. The Romans also used it in medicine and in warfare. During the Middle Ages the alchemists regarded sulfur as the principle of combustibility (phlogiston).

Sulfur was first classified as an element by Lavoisier in 1777 but many of his contemporaries considered it a compound of hydrogen and oxygen. Joseph Gay-Lussac and Louis Thénard finally proved it an element in 1809.

### OCCURRENCE

The earth's crust, according to the classic studies of geochemist F. W. Clarke, contains 0.06% of sulfur as sulfides, sulfates, and elemental sulfur. As elemental or native sulfur, it occurs chiefly in sedimentary and volcanic deposits. Most of the world's production of sulfur is from sedimentary deposits and the majority of that from the calcareous horizons of the cap rock of shallow salt domes in the coastal region of Texas and Louisiana, and the Isthmus of Tehuantepec, Mex. Italy, chiefly Sicily, is the only other large producer from sedimentary deposits. Volcanic sulfur, widely distributed throughout the world, occurs as a sublimate on the walls of vents or permeating porous lava and ash beds. Chief occurrences are in Japan, the Andes Mountains, especially in Chile, and Indonesia. Smaller deposits, formed at or near the surface by atmospheric oxidation, are also widely distributed throughout the world in almost any type of rock, but these are of minor commercial importance.

In combination, the element occurs chiefly as sulfides and sulfates. The former are of importance as a source of sulfur; e.g., pyrite, or iron pyrites ( $\text{FeS}_2$ ), marcasite ( $\text{FeS}_2$ ), pyrrhotite ( $\text{Fe}_{1-x}\text{S}$ ), chalcopyrite ( $\text{CuFeS}_2$ ), galena ( $\text{PbS}$ ), and sphalerite ( $\text{ZnS}$ ). The chief sulfates are anhydrite ( $\text{CaSO}_4$ ), gypsum ( $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ), and barite ( $\text{BaSO}_4$ ) also known as barytes or heavy spar (see PYRITE, MARCASITE; etc.). Sulfur also occurs in organic substances; e.g., hair, wool, albumen, garlic, mustard, horseradish, cabbage, and many proteins.

### PRODUCTION AND USES

Ancient producers described their method of obtaining sulfur from its ores as purification by fire. Similar methods are still used in Sicily where native sulfur ore, mined by conventional methods, is piled in open cylindrical kilns (*calcaroni*), covered with spent ore and ignited. Heat from burning about one-third of the sulfur melts the remainder which drains from the kilns and is cast into blocks. Somewhat better sulfur recovery is obtained in other kilns (Gill furnaces) constructed so that combustion gases from one kiln can be used to preheat the ore in another. In Japan, sulfur is usually distilled from the ore in retorts. Sulfur ores may also be heated with steam or superheated water in autoclaves. The sulfur melts, drains from the gangue (worthless rock), and is recovered in the liquid state. Some sulfur is recovered by this method in the western part of the United States but after 1903 nearly all U.S. sulfur was produced by the Frasch process from the deposits located near the Gulf of Mexico in Texas and Louisiana.

The Frasch process also is used for the bulk of Mexican production.

**Frasch Process.**—All the sulfur deposits mined by the Frasch process occur at depths of 200 to 2,000 ft. in the cap rock of salt domes. In horizontal section, the domes are circular to elliptical in shape. Surrounding and overlying the domes are clay, sand, and gumbo. The upper portion of the dome consists of a porous cap rock which is largely limestone and calcite, with an occasional trace of the carbonates and sulfates of the other alkaline earths. The sulfur occurs in the porous limestone in the form of rhombic crystals. Below the limestone is a stratum of massive anhydrite which in turn overlies the rock-salt core of the dome. (See SALT DOME.)

Crystalline sulfur melts at about  $116^\circ\text{C}$  (about  $240^\circ\text{F}$ ). The Frasch process takes advantage of this fact and fuses the sulfur underground by pumping water heated above this temperature into the deposit. The melted sulfur, which is almost chemically pure, flows away from the gangue and is pumped to the surface.

In mining, wells are drilled into the sulfur formation using rotary rigs such as those employed in the petroleum industry (see DRILLING MACHINERY). Typically, the wells consist of concentrically placed pipes which reach from the surface of the ground into the sulfur deposit. A 6-in. pipe extends, in a typical operation, through the sulfur-bearing stratum and rests in the upper portion of the underlying calcium sulfate, or gypsum. A 3-in. pipe is placed inside the 6-in. pipe, reaching nearly to the bottom of the sulfur-bearing rock but resting on a collar that is set within the 6-in. pipe and seals the annular space between the two. Finally, a 1-in. air pipe, inside the 3-in. pipe, extends to a depth slightly above the collar: The 6-in. pipe is perforated at two levels, separated by the collar, the upper set of holes permitting the escape of hot water and the lower the entrance of molten sulfur.

Hot water is pumped down the annular space between the 6-in. and 3-in. pipes and discharged into the porous formation through the perforations already described. The entire region through which the water circulates is raised to a temperature above the melting point of sulfur. The melted sulfur, being heavier than water, settles and forms a pool around the foot of the well and, entering the lower perforations, rises in the 3-in. pipe. Compressed air, released at the bottom of the central 1-in. pipe, raises the liquid sulfur to the surface. Then the molten sulfur is pumped from the wells to nearby reservoirs, or sumps, and from them to vats (bins) to solidify. A completed vat, consisting of a solid block of sulfur, may be 1,200 ft. long, 50 ft. high, and 160 ft. to 200 ft. wide, and contain 500,000 tons of sulfur. An increasingly important quantity is shipped as liquid (molten) sulfur in specially heated and insulated tank cars, barges, and oceangoing tankers.

**Recovered and By-product Sulfur.**—The sulfur production described is that obtained in elemental form from natural deposits. In addition, increasing quantities of elemental sulfur are recovered from pyrites and from such industrial gases as coke-oven gas, "sour" natural gas, petroleum refinery gases, and from smelter gases from the processing of zinc- and copper-sulfide ores. Producers include Canada, France, Germany, Iran, Iraq, Mexico, Netherlands, Norway, Sweden, Trinidad, United Kingdom, Portugal, and the United States.

World production of elemental sulfur has risen steadily since the early 1900s, and especially with the growth of the chemical industry after World War II, exceeding 12,000,000 tons a year in the second half of the 20th century. Leading producers are: the United States, Mexico, and Canada in North America; Chile in South America; France (at Lacq), Italy (Sicily), Poland, and the U.S.S.R. in Europe; and Japan and mainland China in Asia.

**Commercial Forms.**—Crude sulfur, or brimstone, on the United States market is 99.5% to 99.9% pure and free from arsenic, selenium, and tellurium. As shipped, it contains about 50% fines with lumps 8 in. or more in diameter. Italian sulfur is marketed in four grades known as best seconds, best thirds, good thirds, and current thirds and ranging in sulfur content from 99.5% down to 96.0%. Japanese sulfur is usually marketed in the form of cylindrical bars, each containing slightly more than one cubic foot of 99.8% to 99% sulfur and weighing 130 to 150 lb.

Broken-rock brimstone is sublimed or refined sulfur broken and

sold as a mixture of lumps and fines. It has uses similar to roll sulfur.

Colloidal sulfur is sulfur in such small particles that it remains suspended in water. Colloidal sulfur may be prepared by intensive grinding but is usually prepared by chemical means. The uses are mainly pharmaceutical.

Commercial flour sulfur is produced by grinding crude sulfur. Its fineness is 50% to 99% through 200-mesh or 99% through 300-mesh. Uses: vulcanizing rubber, dyes, gunpowder, insecticides, and fungicides.

Flowers of sulfur is crude sulfur refined by sublimation. It contains from 25% to 30% "amorphous" sulfur, and 90% of it will pass through a 100-mesh sieve. Uses: chemicals, vulcanizing rubber, insecticides, fungicides, and pharmaceuticals (especially after washing with ammonia to remove all traces of acid).

Lac sulfur, precipitated from polysulfide solutions by sulfuric acid, contains up to 45% calcium sulfate. The uses are mainly pharmaceutical.

Precipitated sulfur is precipitated from polysulfide solution by hydrochloric acid and washed to remove all calcium chloride. The uses are mainly pharmaceutical.

Roll sulfur is refined sulfur cast into convenient sizes, also known as stick or cannon sulfur. Uses: chemical, burning for curing, fumigating, and preserving or bleaching effects.

**Uses.**—The uses of sulfur are many and varied. Often it is considered, along with salt, coal, and limestone, as being one of the four basic raw materials of the chemical industry (*q.v.*). The major portion of it is burned to form sulfur dioxide for use in producing wood pulp, for bleaching, and for conversion to sulfuric acid. But sulfur, because of its interesting properties, is also applied to many other uses. Combined with an aggregate, it is used to make acid-resistant cements. It is used to impregnate paper and other porous materials to produce useful articles of commerce. Sulfur ointments have been used in treating skin affections and sulfur compounds are used to treat a variety of diseases. It is used as an insecticide or fungicide in the control of insects and fungus diseases of plants and animals. A further major use is as a plant food. Sulfur and its compounds are used both as direct and indirect fertilizers. As indirect fertilizers, sulfur and its compounds have various functions, including the correction of alkali soils, reaction with soil constituents, and release of the nutrient elements, soil amelioration resulting from the flocculating effect and the control of the reaction of the soil.

### PHYSICAL PROPERTIES

The element sulfur, chemical symbol S, exhibits nonmetallic properties. It occupies the position immediately below oxygen in Group VI of the periodic table. Four stable isotopes are known, each with a nucleus containing 16 protons, but differing by having 16, 17, 18, and 20 neutrons respectively. The respective mass numbers are 32, 33, 34, and 36, and the normal composition of sulfur is given as  $S^{32}$  (95%),  $S^{33}$  (0.75%),  $S^{34}$  (4.2%),  $S^{36}$  (0.017%). Three radioactive isotopes,  $S^{31}$  (half-life 2.6 sec.),  $S^{35}$  (half-life 87 days), and  $S^{37}$  (half-life 5.0 min.), have been prepared.

Pure solid sulfur has a pale yellow colour but its naturally occurring forms may be bright greenish-yellow, straw, or honey yellow, yellowish brown, greenish or reddish to yellowish gray. Just above the melting point sulfur is a transparent yellow liquid which, with increasing temperature, turns dark red and becomes black at 230° C. At the boiling point vapours are generated which turn deep red at 500° C and a straw yellow at 850° C.

Sulfur is tasteless and odourless. It has no action on the skin. It is insoluble in water, highly soluble in carbon disulfide, moderately so in aromatic solvents, and indifferently so in aliphatics. The liquid density varies from 1.808 g. per millilitre at 115° C to 1.599–1.614 g. per ml. at the boiling point. At 200° C (reduced pressure) the vapour density corresponds to  $S_8$  molecules, at 600° C to  $S_6$ , at 1,000° C to  $S_2$ , and at 4,000° C to monatomic sulfur. Increased pressure decreases the dissociation of the vapour. The critical temperature is 1,040° C.

Sulfur is a poor conductor of both heat and electricity and be-

comes charged negatively if rubbed with glass, fur, silk, wool, or hard rubber. On Mohs' Scale, its hardness varies from 1.5 to 2.5. The vapour pressure varies from 0.0002 mm. of mercury at 50° C to 3,824 mm. at 570° C. The coefficient of thermal expansion continuously increases with temperature for the solid while that for the liquid passes through a minimum value. The bond angle, the interatomic distance, and the atomic radius for crystalline  $S_8$  are 105°, 2.12 Å (Å, the angstrom unit =  $10^{-8}$  cm.) and 1.04 Å, respectively. For the  $S_8$  gas the bond angle is 100° but the other two values are the same as for the solid. The ignition temperature of sulfur in air is 261° C.

**Allotropic Modifications.**—A number of crystalline forms of sulfur have been identified by their external appearance and optical properties. These, according to D. M. Yost and H. Russell, Jr., arranged in their suggested order of stability are:

These forms differ in external appearance, crystal structure, and physical properties; e.g., density, solubility, and melting point. Of the allotropic forms, the two most important are rhombic ( $\alpha$ ,  $S_{8a}$ , or  $S_1$ ) and monoclinic ( $\beta$ ,  $S_{8\beta}$ , or  $S_{11}$ ).

Thermodynamically, rhombic sulfur is stable at room temperature and is readily obtained by crystallization from solution in carbon disulfide. It is a yellow solid with a density of 2.07 g. per ml. and melting point 112.8° C (if heated rapidly). Above 95.5° C, the transition temperature, the crystals become opaque and consist of aggregates of the monoclinic form. An X-ray investigation of rhombic crystals has shown that the unit cell is composed of 16 puckered rings of  $S_8$  molecules arranged approximately in layers perpendicular to the C-axis.

Monoclinic sulfur is obtained when molten sulfur is cooled slowly. On breaking the surface crust and pouring off the still-liquid sulfur, the interior of the cooled mass will be found to be filled with needlelike, monoclinic crystals. The density of the monoclinic sulfur is 1.96 g. per ml. and its melting point is 119° C. Under high pressures, the two forms can only coexist at a definite temperature for any particular pressure (*i.e.*, the transition point is raised), and if the pressure is raised while temperature is kept constant, the rhombic form is produced since it is the more dense. This balanced state of affairs continues to 151° C and 1,288 atm.; above this temperature and pressure the monoclinic form cannot exist. The atomic heat of transition is 95 cal.

On standing at room temperature, monoclinic sulfur slowly changes into rhombic sulfur but the outward monoclinic crystalline form is preserved, each monoclinic crystal consisting of an aggregate of very small crystals of rhombic sulfur. Commercial varieties of sulfur such as ordinary brimstone, roll sulfur, and flowers of sulfur consist mainly of the rhombic form and a small amount of insoluble or amorphous sulfur.

Carbon disulfide dissolves both rhombic and monoclinic sulfur, 100 g. of it dissolving 50.4 g. of rhombic sulfur at 25° C, 100 g. at 40° C, and 376.1 g. at 80° C. At 0° C, however, the monoclinic form is 1.28 times as soluble as the rhombic and at 25.3° C it is 1.4 times as soluble. The molecular weight of both forms in this solvent corresponds to  $S_8$ . Another very good solvent for rhombic or monoclinic sulfur is sulfur monochloride,  $S_2Cl_2$ .

Rhombic sulfur melts at 112.8° C; monoclinic sulfur melts at 119° C, but the natural melting point of commercial sulfur is a few degrees lower. This is because liquid sulfur consists of a

mixture of two or three molecular species and time is required before equilibrium is established between them. At 120° C liquid sulfur has a viscosity of approximately 10 centipoises; further heating causes the viscosity to drop to a minimum at about 157° C. At 159° to 160° C the viscosity increases rapidly to a maximum of 932 poises at 186° to 188° C after which it again decreases.

Various explanations have been given for the peculiar viscosity of liquid sulfur. At lower temperatures near the melting point it is supposed that the  $S_8$  or  $S_8$  molecule predominates. As the temperature is increased to 160° C, the eight-membered ring molecules rupture, giving an equilibrium mixture of rings and eight-membered chains. The increasing concentration of these eight-membered chains causes polymerization to long complicated chains. In addition to the long straight chain, it is highly possible that side chains of varying lengths exist. A maximum chain length of 12,000 atoms to 27,000 atoms is attained at approximately 187° C, above which the polysulfur chains break into shorter chains. In addition to  $S_8$  or  $S_8$ , and  $S_8$  or  $S_8$ , still another molecular species of sulfur,  $S_8$  or  $S_8$ , is believed to exist in both the liquid and in the rapidly cooled solid. The percentage of  $S_8$  at 120° C is approximately 3.5% and at 170° C, close to the temperature of maximum viscosity, it reaches a maximum of approximately 6.8%.  $S_8$  is soluble in carbon disulfide while  $S_8$  and  $S_8$  are not.

If hot, molten sulfur is poured into water it forms a clear, soft, sticky, elastic mass known as plastic sulfur. X-ray analyses show a fibre diagram and it is believed that long chains of sulfur atoms are arranged parallel to the direction of stretching. The stress-strain curves for these elastic strings appear very similar to those given by raw rubber. Plastic sulfur becomes opaque and brittle after a few days because of the conversion of most of the  $S_8$  and some of the  $S_8$  into crystalline rhombic sulfur. When treated with carbon disulfide, only part ( $S_8$ ) of this hardened sulfur will dissolve, leaving amorphous or insoluble  $S_8$  and  $S_8$ .

Other allotropic forms have been reported, such as gamma sulfur ( $\gamma S$ , Muthman's  $S_{III}$ , nacreous sulfur). This form, mixed with  $S_8$  and  $S_8$ , is prepared by the crystallization of molten sulfur as it is cooled to 90° C. It is also formed by the slow diffusion of aqueous solutions of sodium thiosulfate and potassium hydro-sulfate. The yellowish-white monoclinic crystals have a mother-of-pearl lustre with axial ratios different from those of beta sulfur. Colloidal sulfur (delta sulfur, Muthman's  $S_{IV}$ ), showing no sign of crystal structure, is formed when hydrogen sulfide gas is passed into a saturated aqueous solution of sulfur dioxide at 0° C or when an alcoholic solution of sulfur is poured into water. Other forms reported are theta sulfur ( $\theta S$ ), which is an unstable pale-yellow tetragonal form; zeta sulfur ( $\zeta S$ ), which is a colourless rhombic plate crystal, and eta sulfur ( $\eta S$ ), which consists of colourless, double refracting hexagonal plates.

### CHEMICAL PROPERTIES

All the metals except gold and platinum combine with sulfur to form sulfides and, in most cases, heat is given off during the union. Moist sulfur is slowly oxidized at ordinary temperatures to sulfuric acid. In combination with metals and hydrogen, sulfur has a valence of -2, forming compounds like  $H_2S$ ,  $FeS$ ,  $CuS$ , and  $HgS$ . In combination with nonmetals, however, the valence or oxidation state may be +4 or +6 as in  $SO_2$  and  $SO_3$  respectively. Other valence states, such as -1 or +2, are more rarely observed. Sulfur is therefore an oxidizing agent as well as a fair reducing agent. Its oxides are acid-forming.

**Sulfides.**—Hydrogen sulfide ( $H_2S$ ) is formed by the reaction of hydrogen with molten sulfur at 200° to 400° C and with sulfur vapour at temperatures up to 800° C. It is also formed by the action of acids on metallic sulfides such as ferrous sulfide,  $FeS + 2HCl \rightarrow FeCl_2 + H_2S$ ; by putrefaction of organic substances containing sulfur; by the destructive distillation of coal; and by heating sulfur with hydrocarbons such as paraffin, petroleum oil, methane, etc.

Hydrogen sulfide, a colourless gas having the odour of rotten eggs, is fairly soluble in water, giving a feebly acidic solution which slowly deposits sulfur when exposed to air. This gas, poison-

ous when inhaled, burns in air with a pale-blue flame to give sulfur dioxide and water. It can be liquefied at 18° C by a pressure of 17 atm., the liquid boiling at -60.1° C under atmospheric pressure and solidifying at -82.9° C. Hydrogen sulfide, often used as a reducing agent, is oxidized by the halogens to sulfur, excess halogen oxidizing the sulfur to sulfuric acid; by hydrogen peroxide to thiosulfate and finally, to sulfate; and by concentrated sulfuric acid to sulfur and sulfur dioxide.  $H_2S$  is thermodynamically stable with respect to  $H_2$  and all forms of sulfur, up to 1,550° C. It can, however, be converted to elemental sulfur in good yield by the Claus process, the overall reaction of which is  $2H_2S + O_2 \rightarrow 2S + 2H_2O$ ; this process is increasingly used to produce sulfur from "sour" gas and oil.

Hydrogen persulfide,  $H_2S_2$ , density 1.3339 (20° C), melting point -89.6° C, boiling point 70.7° C ( $\pm .5$ ), is prepared by decomposing a polysulfide with a strong acid, as by treating  $Na_2S_{2.8}$  with hydrochloric acid. Hydrogen trisulfide,  $H_2S_3$ , may be obtained as a by-product in the reaction. The compounds  $H_2S_6$  and  $H_2S_8$  have also been described. The persulfides all dissolve readily in organic solvents.

The hydrogen atoms in hydrogen sulfide can be replaced by metals to form the normal sulfide,  $M_2S$ , or the acid sulfide,  $MHS$ . Sulfides of the alkali metals dissolve readily in alcohol and in water and are used in the paper and leather industries. Many sulfides, those with high heats of formation, can be made by grinding the metal and sulfur. Others require heating; in some instances a high temperature is necessary to start the reaction. Sulfates, especially those of alkali and alkaline earth metals, can be reduced to the sulfides by heating with carbon. Heavy-metal sulfides, which are all highly insoluble in water (being among the most insoluble of all substances), can be made also by passing hydrogen sulfide through solutions of metal salts. This precipitation with hydrogen sulfide is used in qualitative analysis.

The sulfides of the heavy metals have a characteristic appearance and colour. Some are volatile at moderate temperatures, mercuric sulfide subliming at 446° C. They can be oxidized in air, and many are hydrolyzed by water with the evolution of hydrogen sulfide. Some metallic sulfides containing small amounts of heavy-metal salts are phosphorescent. Zinc sulfide is used in luminous paints and, combined with traces of a radium salt, it is used for painting and figures on luminous watch dials.

**Thio Salts.**—Metallic sulfides react with sulfides of the more negative elements ( $3Na_2S + P_2S_5 \rightarrow 2Na_3PS_4$ ) to give thio salts or sulfo-salts. This reaction is used analytically to separate As, Sb, Sn from Cu, Pb, Bi, Cd, and Hg.

**Polysulfides.**—Sulfur combines with simple sulfides like  $Na_2S$  or  $NaSH$  to form polysulfides having the general formula  $Na_2S_x$  in which  $x$  varies from 2 to 5. (Some  $Na_2S_8$  is formed in liquid ammonia solution.) The polysulfides, well-crystallized hygroscopic solids which are oxidized by air to form thiosulfates, are used by the tanning industry. Lime-sulfur solution, consisting of calcium sulfide and polysulfides, is made by boiling sulfur with a suspension of lime and is used both as an insecticide and as a fungicide.

The sulfides of carbon, silicon, and boron are obtained by direct union of sulfur with these elements at high temperatures.  $CS_2$  is unimolecular. It boils at 46.25° C, while  $SiS_2$  and  $B_2S_3$  are solid compounds which are difficult to volatilize. Both of the latter, in contrast to  $CS_2$ , burn in oxygen with difficulty.  $SiS_2$  and  $B_2S_3$  are hydrolyzed by water.  $CS_2$  is important commercially, being used in the preparation of viscose rayon and carbon tetrachloride and as a solvent. Other sulfides such as  $CS$ ,  $C_3S_2$ , and  $SiS$  are also known. The former, a solid, is prepared by the action of a silent electric discharge on the vapour of  $CS_2$ . Carbon and silicon also form sulfides which contain oxygen or a halogen. Carbon oxy-sulfide,  $COS$ , is always formed when carbon, oxygen, and sulfur are brought together at high temperatures. In its physical properties, carbon oxy-sulfide is intermediate between  $CO_2$  and  $CS_2$ . It is a colourless, odourless gas which condenses to a liquid at -47.5° C.

**Nitrogen Sulfides.**—Another series of compounds is the sulfides of nitrogen. Nitrogen sulfide,  $NS_2$ , is a red liquid. The tetrasulfide,  $N_4S_4$ , a yellow or orange-yellow solid, melting point

179° C, is prepared by passing ammonia through  $\text{SCl}_2$  dissolved in benzene or by dissolving sulfur in liquid ammonia at  $-15.5^\circ \text{C}$ . The material explodes when struck. The pentasulfide,  $\text{N}_2\text{S}_5$ , a red liquid with a melting point of  $10^\circ \text{C}$ , is obtained when the tetrasulfide is boiled with  $\text{CS}_2$ . Nitrogen tetrasulfide has been suggested for use as an ignition promoter in diesel fuels and as an insecticide and fungicide.

**Oxides of Sulfur.**—Sulfur burns readily in air to form  $\text{SO}_2$  and traces of  $\text{SO}_3$ .  $\text{SO}_2$  may also be easily prepared by treating sulfites or bisulfites with a strong acid:  $\text{Na}_2\text{SO}_3 + 2\text{HCl} \rightarrow 2\text{NaCl} + \text{H}_2\text{O} + \text{SO}_2$ . It is available in the liquid form, boiling point  $-8^\circ \text{C}$ , at low cost in steel cylinders. It has many important commercial uses, being used as a bleaching or reducing agent, a refrigerant, and a solvent.

Sulfur monoxide, known only in the gas phase, may be prepared by subjecting a mixture of  $\text{SO}_2$  and sulfur vapour at a pressure of from 1 to 10 mm. to an electric discharge. It may be condensed to a solid at liquid-air temperatures but on melting it converts into  $\text{SO}_2$  and sulfur.

Sulfur trioxide,  $\text{SO}_3$ , is formed by heating  $\text{SO}_2$  and oxygen in the presence of a catalyst such as finely divided platinum, nickel or cobalt sulfates, or the oxides of vanadium, tungsten, molybdenum, chromium, or iron. The equilibrium constant for the reaction is unity at  $790^\circ \text{C}$ ; the conversion is favoured by low temperatures. This reaction is the basis of the contact process for the manufacture of sulfuric acid (*q.v.*).  $\text{SO}_3$  may also be prepared by heating anhydrous ferric sulfate,  $\text{Fe}_2(\text{SO}_4)_3$ , to  $600^\circ$  or  $700^\circ \text{C}$  or by allowing  $\text{SO}_2$  and ozone,  $\text{O}_3$ , to come together at room temperature. Two other oxides of sulfur,  $\text{S}_2\text{O}_3$  and  $\text{SO}_4$ , are known, and  $\text{S}_2\text{O}_7$  has been described. The sesquioxide,  $\text{S}_2\text{O}_3$ , is formed on adding powdered sulfur to liquid sulfur trioxide at  $15^\circ \text{C}$ . It is a blue to blue-green solid which decomposes slowly into  $\text{SO}_3$ ,  $\text{SO}_2$ , and S. Sulfur tetroxide,  $\text{SO}_4$ , a white solid, is prepared by subjecting a mixture of  $\text{SO}_2$  and  $\text{O}_2$  to a silent electric discharge. In the gas phase,  $\text{SO}_3$  consists of monomeric molecules but in the liquid state, boiling point  $46^\circ \text{C}$ , it consists of a mixture of  $\text{SO}_3$  and  $\text{S}_3\text{O}_9$  molecules and perhaps others. It also exists in several solid modifications: the alpha or icelike modification, the beta or low-melting asbestoslike modifications and the gamma or high-melting asbestoslike form. The molecular composition of liquid and solid  $\text{SO}_3$  has not been completely investigated.  $\text{SO}_3$  reacts energetically with organic matter to form sulfonic acid derivatives of carbon and  $\text{SO}_2$ , and with basic oxides to form sulfates. In liquid form it combines with  $\text{NO}_2$  to form oxynitroso sulfuric anhydride,  $(\text{NO}_2\text{SO}_3)_2$ , and with water to form a series of hydrates of sulfuric acid.

The oxides of sulfur dissolve in water to form acids. The following list of the oxyacids of sulfur is from Yost and Russell's *Systematic Inorganic Chemistry of the Fifth-and-Sixth-Group Non-metallic Elements* (copyright, 1944, by Prentice-Hall, Inc., New York). Where the free acid is not known, the fact is indicated by giving the formula of a known salt of the acid in parentheses. In each case a method of preparation of the acid or salt is given:

$\text{H}_2\text{SO}_2$	( $\text{ZnSO}_2$ ) Sulfoxylic. $\text{SO}_2\text{Cl}_2 + \text{Zn}$ in ether solution
$\text{H}_2\text{S}_2\text{O}_4$	Hyposulfurous. $\text{NaHSO}_3$ (aq.) + $\text{Zn}$
$\text{H}_2\text{SO}_3$	Sulfurous. $\text{SO}_2 + \text{water}$
$\text{H}_2\text{S}_2\text{O}_5$	( $\text{K}_2\text{S}_2\text{O}_5$ ) Pyrosulfurous. From solution $\text{KHSO}_3 + \text{SO}_2$
$\text{H}_2\text{S}_2\text{O}_6$	Dithionic. $\text{SO}_2 + \text{aq. suspension MnO}_2$
$\text{H}_2\text{SO}_4$	Sulfuric. $\text{SO}_3 + \text{water}$
$\text{H}_2\text{S}_2\text{O}_7$	Pyrosulfuric. $\text{SO}_3 + \text{H}_2\text{SO}_4$ (100%). Salts, e.g., $\text{Na}_2\text{S}_2\text{O}_7$ , formed by strongly heating $\text{NaHSO}_4$
$\text{H}_2\text{S}_2\text{O}_8$	( $\text{Na}_2\text{S}_2\text{O}_8$ ) Thiosulfuric. $\text{Na}_2\text{SO}_3 + \text{S}$
$\text{H}_2\text{SO}_5$	Peroxymonosulfuric. 30% $\text{H}_2\text{O}_2 + \text{conc. H}_2\text{SO}_4$
$\text{H}_2\text{S}_2\text{O}_8$	Peroxydisulfuric. Electrolysis of $\text{KHSO}_4$ solution
$\text{H}_2\text{S}_n\text{O}_6$	Polythionic, $n = 3, 4, 5, 6$ . In Wackenroder's solution, $\text{SO}_2 + \text{H}_2\text{S} + \text{water}$ .

The sodium salt of hyposulfurous acid, sodium hyposulfite, is an article of commerce and is used as a reducing agent for ground wood pulp and in the dye industry. Sulfurous acid and its salts are excellent and cheap reducing agents and are also used as disinfectants and food preservatives. Calcium bisulfite and magnesium bisulfite are used to extract lignin from wood in the preparation of wood pulp. Thiosulfates are used extensively in photography.

**The Halides and Oxyhalides of Sulfur.**—The halides and

oxyhalides of sulfur, as described by Fritz Ephraim, possess certain properties in common. They are all readily prepared, usually by several methods. All are either gases or volatile liquids. Except for the fluorides, which exhibit great stability, all hydrolyze readily to give acid products which are irritating to mucous membranes. Again, except the colourless, tasteless fluorides, these compounds possess a pungent odour. As one might expect, the physical properties, reactivity, and stability of these materials vary regularly with the position of the halide in the periodic table as illustrated in Tables II and III. Sulfur monochloride and

reacts readily with water to form sulfuric and hydrochloric acids. It fumes in air and has found application as a smoke producer in military operations. Its most useful application is in organic chemistry where it serves as a sulfonating agent.

**Organic Chemistry of Sulfur.**—The organic chemistry of sulfur may be divided into reactions which occur under reducing conditions and reactions which occur under oxidizing conditions. The first type is encountered when elemental sulfur is heated with petroleum hydrocarbons, rubber, or other organic substances. The organic material is sulfurized and hydrogen sulfide is formed as a consequence of sulfur's action as a dehydrogenation agent. The hydrogen sulfide, being a reducing agent, may induce further reactions, particularly with unsaturated compounds, to yield mercaptans and thiophenols which in turn may be alkylated to sulfides e.g., mustard gas. All such sulfur compounds are analogous to similar compounds of oxygen, but differ from them because of dissimilarities in the respective molecular weights and electronic structures. The additional shell of electrons possessed by sulfur may lead to the formation of polysulfides such as the thiokol-type synthetic resins. The resistance of these resins to attack by gas-

line has led to their use as linings for aircraft fuel tanks. The aromatic sulfur compounds, usually nitrogen derivatives, find extensive uses as accelerators in the vulcanization of rubber. The second type of reaction, oxidation of organic sulfur compounds, yields materials which, with the exception of the disulfides and the peroxides, are not analogous to oxygen compounds with respect to structure. The most important of these compounds are the sulfonic acids, alkyl sulfates, and their derivatives which are used extensively as medicinals (sulfa drugs), detergents, lubricants, and dyestuff intermediates.

### ANALYTICAL METHODS

Free sulfur is determined by extraction with carbon disulfide. Amorphous sulfur, present in sublimed sulfur, is not soluble in carbon disulfide but is rendered soluble by heating samples at 100° to 105° C for 18 hr.

Moisture in commercial sulfur is determined by drying a 50 g. sample at 80° C for 16 hr. in a wide-mouth weighing bottle.

Ash in commercial sulfur is determined by burning 10 to 50 g. of the sulfur in a porcelain crucible using sufficient auxiliary heat to keep the sulfur burning and finally igniting the crucible to destroy all organic matter.

Arsenic, selenium, and tellurium in sulfur are determined by first oxidizing the sulfur to sulfuric acid through the use of bromine and nitric acid. Arsenic is then determined by the Gutzeit method, selenium by reduction with hydrazine sulfate, and tellurium by reduction with stannous-chloride solution.

Combined sulfur may be determined by converting it to a soluble sulfate and precipitating it as barium sulfate by the addition of barium chloride.

See also references under "Sulfur" in the Index.

C. L. Thorne and E. R. Roberts, 6th rev. ed. (1954). (W. W. D.)

**SULFURIC ACID**,  $\text{H}_2\text{SO}_4$ , is one of the most widely used of all commercial chemical substances. It is made from sulfur, or compounds of sulfur, water and oxygen from the air. Although rarely used or even seen by the layman, sulfuric acid is employed in some stage of the manufacture of practically all industrial products.

Sulfuric acid occupies its unique position of usefulness because it can be employed for an unusually wide range of purposes and because it is one of the cheapest of the industrial chemicals to produce. Its great affinity for water, i.e., its great tendency to absorb water, makes it a powerful dehydrating agent. It is a valuable electrolyte, a strong oxidizing agent, and a solvent in which many important reactions can be brought about. It is also an effective catalyst for various chemical reactions. It is used in varying concentrations from the extremely dilute solutions for control of acidity or alkalinity to the highly concentrated fuming acids prepared for the manufacture of drugs, dyes and explosives. It is made in various grades from those of high purity for the rayon and pharmaceutical industries to those of relatively low grade for the manufacture of superphosphate and ammonium sulfate for the fertilizer industries. The same batch of acid is often used for several purposes in succession. After an initial use in the petroleum, explosives, drug or dye industries, for instance, it is frequently recovered in a solution too dilute or impure for further use in the same process but still usable for the pickling of steel or manufacture of a fertilizer. Sulfuric acid is made by two very different processes: the contact process and the lead-chamber process. (See *Manufacture*, below.) For use in either process a large variety of sulfur-containing raw materials is available.

**Properties.**—Pure (100%) sulfuric acid is a colourless liquid which is sometimes called monohydrate of sulfur trioxide because its anhydride, sulfur trioxide ( $\text{SO}_3$ ), and water are combined in equimolar quantities ( $\text{SO}_3 + \text{H}_2\text{O} \rightarrow \text{H}_2\text{SO}_4$ ). Its specific gravity is 1.830 at 25° C. (77° F.), freezing point 10.37° C. (50.7°

F.) and at one atmosphere it boils at about 340° C. (644° F.) but undergoes decomposition into sulfur trioxide and water. The former escapes as a vapour until the concentration has fallen to 98.54%, which is the composition of the constant-boiling mixture of sulfuric acid and water at atmospheric pressure. The solution then distills at 317° C. (603° F.), the boiling point of the mixture. The freezing point of the acid is lowered markedly by the addition of either sulfur trioxide or water.

The existence of the following crystalline phases has been established by the study of freezing temperatures and other properties:  $\text{SO}_3$ ,  $(\text{SO}_3)_2 \cdot \text{H}_2\text{O}$ ; i.e.,  $\text{H}_2\text{S}_2\text{O}_7$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ ,  $\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ ,  $\text{H}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ ,  $\text{H}_2\text{SO}_4 \cdot 6.5\text{H}_2\text{O}$  and  $\text{H}_2\text{SO}_4 \cdot 8\text{H}_2\text{O}$ . The hydrate containing 6.5 molecules of water per molecule of anhydrous acid (13 molecules of water for 2 molecules of acid) was believed, prior to publication of careful measurements by J. E. Kunzler and W. F. Giaque, to be a hexahydrate. It is possible (though not likely) that the octahydrate may not have exactly the composition ascribed to it. It is known, however, that the ratio of  $\text{H}_2\text{O}$  molecules to  $\text{H}_2\text{SO}_4$  molecules is less than nine.

Sulfuric acid is dibasic; that is, its molecules each contain two hydrogen atoms and ionize in two steps:  $\text{H}_2\text{SO}_4 = \text{H}^+ + \text{HSO}_4^-$  and  $\text{HSO}_4^- = \text{H}^+ + \text{SO}_4^{2-}$ . The second stage of the dissociation is moderately weak, the constant being 0.010 at 25° C. Solutions of various concentrations of the acid therefore may contain in addition to hydrogen ions ( $\text{H}^+$  or  $\text{H}_3\text{O}^+$ ), molecules of the acid ( $\text{H}_2\text{SO}_4$ ), bisulfate ions ( $\text{HSO}_4^-$ ) and sulfate ions ( $\text{SO}_4^{2-}$ ) in proportions which vary with the dilution. In very dilute solutions the concentration of the  $\text{SO}_4^{2-}$  ion is equal to the stoichiometric concentration; that is, there is an  $\text{SO}_4^{2-}$  ion for practically every molecule of  $\text{H}_2\text{SO}_4$  which was originally added to the water. As the concentration of the solution is increased, the concentration of the  $\text{HSO}_4^-$  rises rapidly; that of the  $\text{SO}_4^{2-}$  increases more slowly and reaches a maximum value of two molar at a stoichiometric concentration of about seven molar. It then decreases to a very small value, virtually zero, in a solution of high concentration (14 molar). At this same high concentration (14 molar) the  $\text{HSO}_4^-$  is at a maximum value of 14 molar, that is, practically all of the acid has undergone primary ionization but no secondary ionization. At still higher molarities the  $\text{HSO}_4^-$  ion concentration diminishes as the  $\text{H}_2\text{SO}_4$  increases.

As a result of these variations in the concentrations of the various molecular species, the properties of aqueous sulfuric acid solutions undergo interesting changes; i.e., the specific conductance reaches a maximum in the 4-molar acid, the specific conductance-viscosity product attains a maximum in the 9-molar solution and the surface tension reaches a maximum when the stoichiometric concentration is about 6.5 molar. At low temperatures (0° C.) there is a minimum in the surface tension-concentration curve at about one molar concentration. Other properties such as density, heat of dilution and heat capacity are also affected by the changes in the concentration of the various components which result from the dissociation of the  $\text{H}_2\text{SO}_4$  molecules.

Dilute sulfuric acid reacts with the more electropositive metals such as zinc, magnesium and iron with the evolution of hydrogen. It also reacts with metal oxides and hydroxides forming sulfates. Because of its high boiling point the concentrated acid is used to manufacture volatile acids (some of them stronger than sulfuric acid) from their salts. It liberates hydrogen chloride gas (hydrochloric acid in water solution) from sodium chloride, nitric acid from nitrates, and hydrofluoric acid from calcium fluoride. It is also used to convert calcium phosphate to a more soluble acid phosphate for fertilizer and in solution displaces numerous weak acids; e.g., acetic and boric acids from their respective salts. Since bromide ion and iodide ion are oxidized by the concentrated acid, it cannot be used for the manufacture of hydrobromic and hydriodic acids.

In sulfuric acid the sulfur is at its maximum oxidation state of +6; it may therefore function as an oxidizing agent and be reduced to the +4( $\text{SO}_2$ ), zero (S) or -2( $\text{S}^{2-}$ ) state. The dilute acid is not an effective oxidizer but the hot concentrated acid oxidizes less active metals (e.g., copper and silver) as well as the

nonmetals carbon and sulfur, and is itself reduced to sulfur dioxide. With stronger reducing agents as zinc or iodide it is reduced to hydrogen sulfide, which under favourable conditions may escape before being oxidized by more of the sulfuric acid.

It removes by oxidation the tars and organic sulfides present in petroleum and serves as a catalyst in the sulfuric acid alkylation processes involved in the manufacture of high-octane aviation gasoline.

The concentrated acid has great affinity for water and serves as an excellent drying agent and as a dehydrating agent, not only removing moisture from gases and liquids which do not react with the acid, but extracting water from compounds. Thus it chars many organic compounds such as wood, paper, cloth, starch and sugars. For the same reason the acid becomes brown in colour if it comes in contact with traces of oil, grease or atmospheric dust. It is essential in the manufacture of explosives, celluloid, lacquers, etc., for the nitration operations involved in these processes liberate water which is removed by the sulfuric acid, thereby permitting the reactions to go to completion. Its value to organic chemistry is due also to its reaction with many aromatic compounds to form sulfonic acids. (See DYES AND DYEING; NAPHTHALENE; PHENOLS; SULFONIC ACIDS.)

**Sulfates.**—Since sulfuric acid is dibasic, it forms both normal or neutral salts ( $\text{Na}_2\text{SO}_4$ ) and acid salts ( $\text{NaHSO}_4$ ). The latter show acid properties in solution because of the ionization of the  $\text{HSO}_4^-$  ion and are sometimes employed for purposes requiring moderate acidity. The common sulfates are soluble in water with the exception of those of lead, strontium, barium and calcium. Many of the sulfates have important industrial uses: barium and lead sulfates in the manufacture of paints; sodium sulfate in the manufacture of paper, and its hydrate,  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$  (Glauber's salt), in medicine; copper sulfate,  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ , in insecticides and its solution as an electrolyte in the electrolytic refining of copper; gypsum,  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ , and plaster of paris,  $(\text{CaSO}_4)_2 \cdot \text{H}_2\text{O}$ , in the building industries. The sulfates of potassium and aluminum crystallize from solution as a double salt,  $\text{K}_2\text{SO}_4 \cdot \text{Al}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$ , which is called alum (*q.v.*). The term is also applicable to other double sulfates of similar crystalline form in which the potassium ions are replaced by other univalent ions (*e.g.*, those of sodium or ammonium) and the aluminum ions by other trivalent ions (*e.g.*, those of chromium or iron).

**Grades and Terminology.**—Since there is a linear relationship between the concentration and density of sulfuric acid in the range from 0% to 93.19%, the concentration may be determined fairly accurately with the aid of a hydrometer. The Baumé (Bé.) hydrometer, American modulus, is used by the industry in the U.S., while in continental Europe it is employed with a different modulus. The Twaddell hydrometer is used in the United Kingdom although there is an increasing tendency to express the concentration directly in percentage of  $\text{H}_2\text{SO}_4$  or of  $\text{SO}_3$  rather than in the degrees of the hydrometer scale. Temperature corrections must be made for all hydrometer readings (*see* HYDROMETER).

The 100%  $\text{H}_2\text{SO}_4$  is rarely shipped because of its high freezing point (*see* above); the 98%–99% acid which is produced in the contact process is frequently used and because of its somewhat lower freezing point may be shipped if care is exercised.

The 93.19% acid is a sirupy, oily liquid whose freezing point is  $-34^\circ \text{C}$ . ( $-29^\circ \text{F}$ .) and boiling point  $281^\circ \text{C}$ . ( $538^\circ \text{F}$ .); at  $15.6^\circ \text{C}$ . ( $60^\circ \text{F}$ .) its specific gravity is 1.835 and its viscosity 24 times that of water at the same temperature. It is one of the most popular shipping concentrations because of its low freezing point and the fact that it does not substantially react on and corrode the economical steel containers at atmospheric temperatures. The name oil of vitriol (*o.v.*) is used in the U.S. to designate this concentration of the acid because of its appearance and "irritant" characteristics. In the United Kingdom and Europe, however, the term is used more generally to mean simply sulfuric acid. Thus, in the British Isles the following designations are used: brown oil of vitriol (*b.o.v.*), ordinary commercial 77%–80% acid; best brown oil of vitriol (*b.b.o.v.*), the commercial 77%–80% acid relatively free from arsenic and other impurities; concentrated or

rectified oil of vitriol (*c.o.v.* or *r.o.v.*), 93%–96% acid now usually made by the contact process rather than by concentration or rectification of the more dilute chamber acid. The term chamber acid may refer either to any acid produced by the lead-chamber process or to the acid of the particular concentration 62%–68% otherwise produced. This more dilute acid reacts with steel containers and is therefore rarely shipped in quantity. The term 50° Bé. acid (62.18%) is frequently used for statistical purposes in the U.S. Acids of still lower concentrations are sometimes prepared by dilution but must be shipped in the more expensive glass carboys or bottles.

Another popular shipping strength is the approximately 78% acid because it is the maximum strength made by the chamber process and because its freezing point,  $-10.8^\circ \text{C}$ . ( $12.6^\circ \text{F}$ .), is low. In cold climates the shipping concentration is often changed to 76%, which acid has a still lower freezing point. The 76%–78% acid is not seriously corrosive to steel tank cars or tank trucks. The fertilizer industry, one of the largest consumers of sulfuric acid, requires acid of only 68% concentration for the manufacture of superphosphate.

Oleum or fuming sulfuric acid (also known as Nordhausen acid) is a solution of sulfur trioxide,  $\text{SO}_3$ , in 100% sulfuric acid. Its concentration is usually expressed as "per cent oleum," *i.e.*, the percentage of free  $\text{SO}_3$  dissolved in the acid, and occasionally as the total percentage of  $\text{SO}_3$  which includes both the free oxide and that combined with water in the  $\text{H}_2\text{SO}_4$ . Thus 100 lb. of 40% oleum contains 40 lb. of  $\text{SO}_3$  and 60 lb. of 100%  $\text{H}_2\text{SO}_4$ , or a total of 89 lb. (89%) of  $\text{SO}_3$  free and combined. Addition of 9 lb. of water to the 100 lb. of 40% oleum yields 109 lb. of 100%  $\text{H}_2\text{SO}_4$ . For this reason oleum has an equivalent acid concentration greater than 100%  $\text{H}_2\text{SO}_4$ , that of the 40% oleum being 109% acid. As sulfur trioxide dissolves in sulfuric acid in all proportions, the resulting oleums may have a wide range of concentrations. When the two combine in equimolar proportions, pyrosulfuric acid,  $\text{H}_2\text{S}_2\text{O}_7$ , is formed. This acid has the maximum melting point,  $36^\circ \text{C}$ . ( $96.8^\circ \text{F}$ .), of all the compounds of the  $\text{H}_2\text{O}$ – $\text{SO}_3$  system.

Sulfuric acid may also be designated by terms which refer to its purity, origin or use rather than to its concentration. Thus battery acid and electrolyte refer to acid of a quality suitable for accumulators or storage batteries; in the U.S. the concentrations sold are either 50%  $\text{H}_2\text{SO}_4$  (specific gravity 1.40) or 93.19% (specific gravity 1.835). Brimstone (or sulfur) acid refers usually to acid produced from sulfur rather than from less pure raw materials such as pyrites, spent oxide, and so on.

Mixed acid consists of nitric acid and concentrated sulfuric acid. Spent acid is that which has been used once and is usually dilute and impure. Sludge acid is the residue of the acid used in the refining of petroleum. It is contaminated with organic impurities and is frequently made usable by further dilution to separate as many of the impurities as possible followed by concentration; or it may be decomposed by heat, the organic material oxidized and the sulfur dioxide recovered for use in the manufacture of more acid. Spent alkylation acid is a by-product of sulfuric acid alkylation processes for the manufacture of high-octane aviation gasoline. It is of a higher purity than sludge acid, usually containing 85%–90%  $\text{H}_2\text{SO}_4$ , and is frequently reused in the petroleum refinery.

Like other chemicals, sulfuric acid is graded by standards stipulated by the appropriate scientific societies or industries. The technical grade is usually intended for large-scale industrial use and need not be of high purity. The U.S.P. label designates acid which meets the specifications of the *United States Pharmacopeia*, while C.P., chemically pure, refers to acid of a higher grade, usually prepared by distillation of a commercial grade acid. The purest grades, suitable for analytical and research purposes, are designated as reagent, analyzed, and so on.

**Materials of Construction of Containers.**—Of the common metals, only lead is satisfactorily resistant to cold sulfuric acid of nearly all concentrations up to 100% and to hot acid of concentrations up to about 70%. Generally the metals are less resistant to the hot and the more concentrated acids, but steel and cast iron are exceptional in that they are resistant to cold

acid of concentrations higher than about 78% because of the formation of a protective scale and are attacked with increasing effect as the concentration decreases. Cast iron is more resistant than mild steel to acid of most concentrations and has a satisfactory life even with very hot acid, provided its concentration exceeds 90%. However, cast iron should never be used as a container for oleum or for sulfur trioxide gases, since it may crack with explosive violence when in contact with sulfur trioxide. Mild steel should not be used at temperatures in excess of approximately 49° C. (120° F.) regardless of the concentration of the acid but it has a satisfactory life for acid of concentrations exceeding 20% oleum even though hot. Cast steel, malleable iron and many resistant alloys are available for specific concentrations, temperatures and applications; in some instances acid-resistant brick linings are used (e.g., for hot oleum at less than 20%).

The U.S. Interstate Commerce commission issued regulations in 1946 permitting the use of rubber-lined metal containers for acid up to 42° Bé. (about 50%). Lead-lined containers may be used for acid up to and including 93.2%. Steel tank cars and tank trucks may be used for acid of not less than 52° Bé. (about 65%), but steel drums or barrels which are made of thinner metal may not be used for acid less than 60° Bé. (about 78%); even then only if the acid has no greater corrosive effect than 93% acid at 37.7° C. (100° F.).

Moisture should be carefully excluded from iron or steel containers, since dilution of the acid at any point prompts rapid corrosion. Sparks or open flames must be kept away from any closed vessel, which should not be opened unless it is previously washed and the residual acid neutralized. The vapour space over the acid may contain explosive hydrogen and poisonous arsenic, nitrogen or sulfur compounds.

**Manufacture.**—The date of the discovery of sulfuric acid is lost in antiquity; it was probably first prepared by Arabian chemists (8th century A.D.) and was apparently well known to the alchemists. Near the end of the 15th century Basil Valentine described a method of preparation in which the acid was distilled from a mixture of green vitriol ( $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ ) and silica and another method whereby the acid was obtained by burning sulfur with saltpetre ( $\text{NaNO}_3$ ). The older of the two commercial methods, the lead-chamber process, was introduced in England in 1746 although the principles of the process had been used much earlier. It was first manufactured on a commercial scale from weathered pyritic shales in Bohemia and at Nordhausen in Germany.

The first step in the manufacture of sulfuric acid is to prepare sulfur dioxide ( $\text{SO}_2$ ) gas by burning sulfur or sulfur-bearing materials such as iron pyrites, copper and zinc ores, spent oxide from gas plants and coke ovens, hydrogen sulfide from natural gas and petroleum refinery gas. It is also obtained by decomposition of various sulfates: gypsum ( $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ), anhydrite ( $\text{CaSO}_4$ ), ferrous sulfate ( $\text{FeSO}_4$ ) from waste pickling liquors, sludge acid and spent acid. The raw material used by a particular plant is determined by a number of considerations of great complexity which may include the location, the kind of process employed, the grade and concentration of acid to be produced and the cost. In the U.S. about 75% of the reported production of new acid at mid-20th century came from sulfur, 15% from pyrites, pyrrhotite and coal brasses, 9% from copper and zinc smelters and 1% from hydrogen sulfide. In the U.K. approximately 40% of the production came from sulfur, 28% from pyrites, 20% from spent oxide, 12% from zinc blende and minor quantities from anhydrite and hydrogen sulfide.

The next step in the production of the acid is to oxidize the  $\text{SO}_2$  to  $\text{SO}_3$ . This is done by two different processes both employing catalysts. The lead-chamber process yields acid of a concentration of not more than 78%, and unless a pure raw material (e.g., sulfur) is used, the product is impure. The newer contact process was developed on a commercial scale in the 1890s and is used to produce acid of any desired concentration and of high purity regardless of the quality of the raw materials.

Because of the increasing demand for acid of high concentration and purity, the latter process has steadily gained and by mid-

20th century about 80% of the acid produced in the U.S. and more than one-half of that produced in the U.K. were manufactured by the contact process. The two methods, however, remained competitive under certain circumstances.

**Contact Process.**—Contact plants are of two main types. The newer and simpler type, often known as a raw gas or hot gas purification unit, was developed especially for use with vanadium pentoxide ( $\text{V}_2\text{O}_5$ ) or other catalysts immune to impurities in the gas stream, and with sulfur as the raw material. The other kind, known as the cold gas purification or simply the purification type, is used when the  $\text{SO}_2$  gas contains dust and other impurities from the ores which constitute the raw material.

**Sulfur-Burning Contact Plants.**—In these plants the sulfur is melted to remove moisture and to permit the major portion of the dust or ash which may be present to settle. The molten sulfur with or without subsequent filtration is pumped to the burner. Combustion air (i.e., air which has been dried by concentrated sulfuric acid) is supplied to the burner by a blower operating under a pressure between 1.5 and 3.5 lb. per square inch greater than that of the atmosphere, thus preventing the infiltration of moist air into the plant. The  $\text{SO}_2$ -air mixture containing 8%–11% of  $\text{SO}_2$  leaves the sulfur burner at temperatures which range from about 760° to 1,200° C. (1,400° to 2,200° F.), the temperature being proportional to the percentage of  $\text{SO}_2$  in the gases and to the level of heat energy in the combustion air. Except in very small plants the gas is usually cooled by means of a waste-heat boiler to approximately 400° C. (750° F.), and in some instances is passed through a hot-gas filter to remove any remaining dust or ash before it comes into contact with the catalyst.

The catalyst is placed in layers on shelves or packed in vertical tubes in an insulated steel tank or tower called a converter. The reaction,  $2\text{SO}_2 + \text{O}_2 \rightleftharpoons 2\text{SO}_3 + 45$  kilocalories, takes place at an almost imperceptible rate without a catalyst. However, the rate is greatly increased by the surface catalysts,  $\text{V}_2\text{O}_5$  or finely divided platinum and further accelerated at elevated temperatures. Practically all substances have some degree of catalytic action at high temperatures, but the two mentioned are the most effective, and, because of its relative immunity to impurities,  $\text{V}_2\text{O}_5$  after 1925 gradually replaced platinum in nearly all plants. The fraction of the  $\text{SO}_2$  converted to  $\text{SO}_3$  decreases at excessively high temperatures. The temperatures at which the catalysts function effectively to give quickly the maximum yield of  $\text{SO}_3$  exceed about 400° C. (750° F.) for  $\text{V}_2\text{O}_5$  and 360° C. (680° F.) for platinum. To avoid excessively high temperatures from the exothermic reaction, which would diminish the yield of  $\text{SO}_3$ , the conversion is carried out in stages with removal of part of the heat of reaction by waste-heat boilers or other means between the stages. The gas leaves the final layer of catalyst usually at temperatures between 438° C. (820° F.) and 460° C. (860° F.). In the development of the many types of converter with various arrangements and amounts of catalyst a high efficiency has been achieved whereby 95% to more than 98% of the  $\text{SO}_2$  is converted to  $\text{SO}_3$ .

The  $\text{SO}_3$  gas from the converter is cooled and passed into the absorption system where it is absorbed in 98%–99% sulfuric acid. It combines with the free water in the acid solution to form more  $\text{H}_2\text{SO}_4$ , thus increasing the concentration to any desired value up to 100% or to higher than 40% oleum. The  $\text{SO}_3$  is more readily absorbed by concentrated sulfuric acid than by water, for with the latter fog particles consisting of minute drops of  $\text{H}_2\text{SO}_4$  are formed and can be recovered only with great difficulty and expense. Lower concentrations of the acid may be prepared by dilution of the 99%–98% acid with water. The contact process may also be used to fortify spent acid or the more dilute acid produced in a chamber plant.

Sulfur-burning contact plants with capacities in single units up to 600 tons per 24 hours and requiring only one operator have been built. Considerably more than a ton of high-pressure, saturated or superheated steam may be generated for every ton of 100% acid produced. The required electric power is usually less than 35 kw.hr. per ton of 100% acid and the cooling water about 4,000 U.S. gallons per ton of acid. No buildings are needed for the housing of equipment.

**Purification Types of Contact Plants.**—For production of  $\text{SO}_2$  from low grade sulfur-bearing materials a large variety of furnaces or roasters is available. It is desirable to select a roaster which will remove the maximum quantity of sulfur from the raw materials with a minimum carry-over of dust into the effluent gas and which will produce gas with a maximum  $\text{SO}_2$  concentration at minimum operating and repair costs. It is also desirable to avoid the oxidation of  $\text{SO}_2$  to  $\text{SO}_3$  in the burner and the consequent formation of the acid mist. The concentration and purity of the  $\text{SO}_2$  gas from the furnace determines the size, quantity and cost of subsequent gas-purification equipment.

The gas usually leaves the roaster at temperatures between  $650^\circ\text{C}$ . ( $1,200^\circ\text{F}$ .) and  $1,100^\circ\text{C}$ . (about  $2,000^\circ\text{F}$ .) and may be cooled by cast-iron pipe or by waste-heat boilers. It is important to remove the dust at this stage to prevent its deposit in subsequent equipment. This is done by various methods: about 80%–90% may be removed in cyclone centrifugal collectors and 90%–99% of the remaining dust in electrical precipitators which operate at 50,000 to 70,000 v. and at  $150^\circ$ – $430^\circ\text{C}$ . (about  $300^\circ$ – $800^\circ\text{F}$ .). Precipitators have the advantage of low pressure drop, low power consumption and of recovery of dust in dry form but at the disadvantage of relatively high cost. This equipment may be built of steel or of steel lined with firebrick, as the gas is normally so hot that no corrosive acid can condense. Some plants have replaced precipitators with proprietary gas washers which have as high or higher efficiencies in removal of dust and have the additional advantages of removing a large portion of other impurities such as metallic fume, arsenic and acid mist while simultaneously cooling the gas. They have the disadvantage of relatively high pressure drop, as do cyclone dust collectors. They necessitate recovery of dust in the wet condition but in many cases this is considered an advantage. Smaller and older plants occasionally use dust-settling chambers or scrubbing towers of various types instead of precipitators or gas washers.

After removal of the dust the gas must be cooled to permit removal of other impurities such as metallic fume, acid mist and fluorine, chlorine or arsenic compounds. They must be removed to the point where they do not clog or damage subsequent equipment and do not adversely affect the quality of the product acid for the purpose for which it is to be used. Purification is necessary regardless of the type of catalyst used but the purification equipment need not be quite so carefully designed and operated if a catalyst like vanadium pentoxide which is immune to all common impurities except fluorine compounds is used. Cooling of the gas is necessary not only to remove impurities but also to condense and thus remove part of the water vapour in the gases. If all of the water vapour were allowed to remain in the gas, it would make the product acid in many cases more dilute than desired.

After cooling and removal of impurities, the  $\text{SO}_2$  gas is dried with concentrated sulfuric acid. Equipment after the drying tower is much the same as in sulfur-burning plants with the single exception that waste-heat boilers cannot be employed to recover the heat evolved in the converter. As a result of its purification, the gas in this process is cold, instead of hot as in sulfur-burning plants, and must be heated to the temperature at which the catalyst begins to function. The energy evolved in the converter is utilized for this heating by passing the hot  $\text{SO}_3$  gas and the cold  $\text{SO}_2$  gas through a series of insulated tubular heat exchangers built of steel. The  $\text{SO}_2$  gas is thus heated and the  $\text{SO}_3$  gas cooled.

Contact plants of this type have been built with a single purification line that can produce 300 tons of 100% acid per 24 hours and that serves two 300-ton conversion and absorption lines. The labour, cooling water, power and maintenance requirements are much higher than in sulfur-burning plants because of the additional roasting and purification equipment. However, in many cases the  $\text{SO}_2$  gas is obtained at little or no cost from copper and zinc smelters or from other low-cost raw materials and the cost of the product acid may be substantially less than that from sulfur-burning plants.

**The Lead-Chamber Process.**—This process derives its name from the use of large chambers of sheet lead and differs radically from the contact process, particularly in its use of gaseous oxides

of nitrogen whose function may be considered to be catalytic. The chemical reactions which occur in the lead-chamber process are more complex than those in the contact process, and there is not unanimity of opinion as to their mechanisms. It is thought that the catalyst reacts with  $\text{SO}_2$  gas, oxygen and water vapour to form the intermediate compound, nitrososulfuric acid ( $\text{ONHSO}_4$ ), which in turn reacts with water to form sulfuric acid and the oxides of nitrogen ( $\text{NO}$  and  $\text{NO}_2$ ). Thus the catalyst goes through repeated cycles, combining with the  $\text{SO}_2$ ,  $\text{O}_2$  and  $\text{H}_2\text{O}$  to form the intermediate compound and being set free again with the simultaneous formation of  $\text{H}_2\text{SO}_4$ .

The  $\text{SO}_2$  gas is generally produced in the same manner as in the contact process. However, if it is impure, *i.e.*, obtained by the roasting of ores or by the burning of spent oxide, the purification is carried out only to the extent that the dust and other impurities are not present in quantities sufficient to clog the equipment. This less efficient purification obviates the necessity of cooling the gas which is needed in the next stage of the process at a high temperature, preferably in excess of approximately  $600^\circ\text{C}$ . ( $1,100^\circ\text{F}$ .), and is necessarily at the expense of the quality of the product acid.

After the hot sulfur dioxide-air mixture has undergone the necessary purification, it is passed in succession upward through the Glover tower, through the lead chambers and upward through the Gay-Lussac towers, nearly all of the  $\text{SO}_2$  being removed in the first two steps. The Glover tower is a large masonry structure in some instances sheathed outside with lead. It is packed with lumps of loose quartz, acid-resisting brick or ceramic shapes so that the hot gases are brought into intimate contact with acid which trickles downward through the packing.

The Glover tower has two main functions: (1) to concentrate the approximately 65% acid made in the chambers to 78% acid, the water vapour thus released entering the chambers with the gas stream; (2) to remove the nitrogen oxides from the 78% acid (nitrous vitriol) which has been used in the Gay-Lussac tower to absorb these oxides released at the end of the process and to return them to the cycle. The denitrification is accomplished by dilution of the 78% nitrous vitriol with the less concentrated chamber acid and by the elevation of the temperature of the mixture by the entering hot gases. The gases also begin to react and a substantial amount of sulfuric acid is formed in the Glover tower. The 78% acid drawn off at this point is hot and contains only traces of the oxides of nitrogen. After cooling, part of it is transferred to the Gay-Lussac towers where it is used to absorb the oxides of nitrogen released from the chambers. The balance of it represents the production of the plant and is delivered to steel storage tanks.

The cooled gases leaving the Glover tower proceed to the rectangular boxlike lead chambers which may vary in size from 5,000 to 500,000 cu.ft. and in number from 1 to 20. The large chambers afford sufficient space and time for the gases which do not mix rapidly to react completely. The additional water necessary for the reactions is supplied through atomizing nozzles in the tops of the chambers. The sulfuric acid forms as a rain, drops to the bottom of the chambers and is pumped to the Glover tower. A large amount of energy is evolved by the reactions and cooling is by the natural circulation of air around the chambers which are set well above the ground. The chambers are usually housed in a building to lessen the effect of varying atmospheric conditions on the operation. As the gases pass through the Glover tower and the chambers, their  $\text{SO}_2$  content gradually decreases to 0.1% or less, this amount being desirable for the optimum recovery of the nitrogen oxides in the Gay-Lussac towers.

The Gay-Lussac towers, usually two arranged in series, are similar in construction to the Glover tower but are taller and of smaller diameter. They have thinner walls and linings because they receive relatively cool gases. Their only function is to recover the nitrogen oxides in the spent gases and for this purpose cool 78% acid is used. The recovery is incomplete, and usually 10%–15% of the oxides is lost, constituting an appreciable item of expense. Hence, fresh oxides of nitrogen must be constantly supplied to the process. In some plants the fresh nitrogen oxide

are made from sodium nitrate and 78% sulfuric acid which is heated in an iron pot either by the hot  $\text{SO}_2$  burner gases or by fuel. This method is obsolete at most plants and "nitre pots" have been superseded by ammonia oxidation units. Such units produce oxides of nitrogen by catalytic action of an incandescent platinum alloy gauze on a mixture of air and ammonia (about 9%). The oxides of nitrogen are then introduced into the process usually at the Glover tower inlet or outlet. The gases may be propelled through the chamber plant by the natural draft created by the final Gay-Lussac tower and its exit stack but usually one or more lead or alloy fans are employed. Such a fan may be located between the Glover tower and the first chamber, after the last chamber or at both points.

Because of the considerable lead and space requirements of the chambers, the lack of efficient cooling and the necessity for a large building, many variations of the process are in existence in which the boxlike chambers have been superseded by towers or by chambers of other shapes designed to promote more intensive gas mixing. Some are water cooled externally while some depend on cooling by the internal circulation of large quantities of acid. The principal successor in the U.S. is the Mills-Packard water-cooled chamber constructed in the shape of the frustum of a cone and first developed in England in 1914. By this means the chamber space required was reduced from 6 to 9 cu.ft. (.2 to .3 cu.m.) per pound of sulfur burned, in the case of air-cooled box chambers, to 2.0-3.5 cu.ft. (.05 to .10 cu.m.). No building is required for the Mills-Packard chambers. In the U.K. the Gaillard-Parrish chamber replaced the box chamber in some instances. It is relatively tall but cylindrical in shape and is cooled by a spray of 65% acid from a horizontal rotating disk (dispenser) through the closed top. The Gaillard dispenser has also been used in the tops of box chambers to increase their acid-making capacity. Various processes have also been evolved in which a series of packed towers take the place of the box chambers and in which the oxidation of  $\text{SO}_2$  takes place largely in the liquid phase. Among these may be mentioned the Opl, the Kachkaroff-Guareschi and the Petersen processes, much used in Europe but not in America.

**Concentration.**—Concentration of sulfuric acid by evaporation of the water is practised intensively only at explosives and dye works or in petroleum refineries, where a dilute acid appears as a by-product which must be recovered and concentrated for reuse. A variety of types of equipment is used for this purpose, among which are the Cascade, Kessler, Gaillard, Pot, Simonson-Mantius and Chemico concentrators. They may be divided into three classes: (1) those like the Cascade process in which the acid is heated to its boiling point in acid-resisting basins by heat applied to the exterior of the vessel; (2) those like the Chemico drum concentrator in which the acid is brought into direct contact with a mixture of hot air and gases from the combustion of a fuel; and (3) those like the Simonson-Mantius concentrator in which the acid in a closed vessel under high vacuum is heated indirectly by steam.

Concentrators in the first two classes operate at substantially atmospheric pressure and consequently the acid temperatures are high, especially where hot air in direct contact with the acid is used. The exit gases may contain appreciable quantities of acid mist, which is recovered in coke-packed towers and electrical precipitators.

Concentrators of the third class operate at relatively low temperatures because of the high vacuum and create so little nuisance that precipitators are not required.

**First Aid.**—The best first-aid measure for a sulfuric acid burn is "a lot of water quickly." Speed in removing the acid is of utmost importance, but small amounts of water must not be used because much heat is generated by dilution of the acid and the burn is thus made more severe. Neutralizing agents and ointments are dangerous and should never be used until the burned area has been washed completely free of acid with water. After this has been done the burn may be treated in the same manner as a heat burn.

**SULLA, LUCIUS CORNELIUS** (138-78 B.C.), Roman general and dictator, wrought great constitutional reforms. He sprang from an old but undistinguished patrician family and in his youth had something of a reputation as a fop. As quaestor, however, in 107 he joined the staff of Gaius Marius in Africa and in 105, by a piece of trickery, contrived the capture of the Numidian king Jugurtha. Though by this he attracted attention to himself and earned Marius' jealousy, he continued to serve on Marius' staff in the war against the Cimbri and Teutones in Gaul. After his praetorship in 93 he governed Cilicia in 92 and secured from Mithradates VI Eupator, king of Pontus, the restoration to Cappadocia of King Ariobarzanes, whom Mithradates had expelled. Sulla returned to Italy to fight (as Marius also fought) in the Social War against the Italian *socii*, or allies; and was elected consul for 88, in which year he contracted important political alliances by marrying, as his fourth wife, Caecilia Metella, widow of M. Aemilius Scaurus. As consul he received command of the war against Mithradates (*q.v.*).

The tribune P. Sulpicius Rufus, however, in the interest of the party of the *Populares*, carried a bill at Rome transferring the command in this war from Sulla to Marius. Sulla went at once to his legions in Campania and marched on Rome. Sulpicius was killed, Marius escaped, and measures were hurriedly improvised to prevent a recurrence of this type of tribunician interference in Roman politics, which had been recurrent in the 45 years since the tribunate of Tiberius Gracchus. Sulla then set out for the east. Athens, which had joined Mithradates, was captured after a long siege in 86, and Mithradates' general Archelaus was defeated at Chaeronea and Orchomenos. Negotiations followed; and at Dardanus in the Troad in August 85, Sulla, anxious about the situation in Italy, offered Mithradates terms, which he accepted. He had to abandon all captured territory, to surrender his fleet, and to pay an indemnity. After imposing a heavy fine of 20,000 talents on the province of Asia and introducing emergency measures for the reinstitution of Roman taxation in the province, Sulla in the summer of 83 returned to Italy with an army of about 40,000 men and with a wealth of plunder that included, from Athens, the works of Aristotle, most of them still at that date unpublished.

During his absence the Popular party had had its own way under the leadership of L. Cornelius Cinna, Marius having died in 86. Sulla's political measures of 88 had been rescinded; Sulla himself had been declared a public enemy (86), and an ineffective successor, the former consul L. Valerius Flaccus, had been sent out to replace him. Flaccus, however, was murdered at the instance of his lieutenant Gaius Flavius Fimbria, who in his turn came to no less ignominious an end. On his return to Italy Sulla was joined by those opponents of the Popular regime who had saved their lives by going underground during his absence, notably by that Gnaeus Pompeius whom three years later he was to salute as "Magnus"—Pompey the Great. In 83 Pompey was 23 years old, and he commanded an army that he had raised in his native Picenum. Cinna having been murdered in 84, Sulla's opponents were Gnaeus Papirius Carbo and the younger Marius, consuls for 82, with forces raised in the main from Samnium and Etruria. There followed the first full-scale civil war in Roman history, ended in 82 by Sulla's victory in the Battle of the Colline Gate (in the northern suburbs of Rome) and by the siege and capture of Praeneste (Palestrina), held by the young Marius, who committed suicide after the surrender. The infamous proscriptions followed.

The *Lex Valeria* of 82, whereby Sulla was appointed dictator, was contrary to precedent in that it set no limit of time on his tenure of the office. He celebrated a spectacular triumph for his successes in the east; and as dictator in 81 and as both dictator and

consul in 80, he carried through a vast program of constitutional reform, a series of *Leges Corneliae*, mainly designed to reestablish the supremacy of the Senate in the Roman constitution. Much of this reform was statesmanlike and survived to the end of the republic: in particular, a new treason law, the *Lex Cornelia maiestatis*, designed to check insubordination on the part of provincial governors and army commanders; an increase in the number of standing courts for criminal trials, the *quaestiones perpetuae*; and an arrangement by which the 20 quaestors elected each year should pass automatically into the Senate. Others of his reforms were partisan and inevitably short lived: the return to the system that Gaius Gracchus had overthrown, by which only senators might serve as jurors in the *quaestiones*; and the virtual elimination of the tribunate as an effective force in Roman political life, since the tribunes were now completely or virtually debarred from introducing legislation, and former tribunes were not allowed to hold the higher magistracies of state. Worst of all was the ruthless manner in which Sulla's discharged troops and supporters were settled in the Italian countryside, whether in colonies (for instance, Pompeii) or in districts from which the existing inhabitants were evicted. These settlers were the much hated "Sullan."

In 79 Sulla startled Rome by resigning the dictatorship and retiring into private life. He lived for a year longer, in Campania, writing the memoirs of which Plutarch was to make such extensive use and enjoying the company of the raffish bohemian society in which his youth had been spent.

This resignation—"elementary ignorance," Julius Caesar called it later—constitutes a puzzle that has never been solved. Was Sulla just bored? Was his health beginning to fail? Or did he think that, with senatorial authority reestablished, his task was finished? The evidence does not fully support J. Carcopino's hypothesis that Sulla had all the time been aiming not at the restoration of republican government but at establishing something like the principate that Augustus was to establish later; and that, his scheme detected, his most powerful backers, led by the Caecilii Metelli, turned on him and forced him to resign, using as instruments Pompey, who was certainly on bad terms with Sulla at the end, and Cicero, whose first important speech, *Pro Roscio Amerino*, in 80 or 79 was a bold attack on the Sullan regime.

Sulla was the most superstitious of men, believing himself to be the particular object of divine favour. He expressed his belief in his own luck by assuming, late in 82, the name Felix (in Greek, Epaphroditus). In the same spirit he had given his children earlier the unusual first names of Faustus and Fausta ("fortunate"). Faustus married Pompey's daughter and was killed in 46, having fought on Pompey's side against Julius Caesar; Fausta, even in the Roman society of the last years of the republic, was a notorious profligate.

**SULLIVAN, SIR ARTHUR SEYMOUR** (1842-1900), English composer who, with W. S. Gilbert, established the distinctive national form of the operetta. Born in London on May 13, 1842, he was the son of an Irish musician who became bandmaster at the Royal Military College; his mother was of Italian descent. He joined the choir of the Chapel Royal and later held the Mendelssohn Scholarship at the Royal Academy of Music, London, where he studied under Sir W. Sterndale Bennett and Sir John Goss. His studies were continued at the Leipzig Conservatory, where his teachers included I. Moscheles, J. Rietz, and F. David. In 1861 he became organist of St. Michael's, Chester Square, London, and in the following year his music to *The Tempest*

THE BETTMANN ARCHIVE

SIR ARTHUR SULLIVAN

achieved great success at the Crystal Palace. Then followed his *Kenilworth* cantata (1864), a ballet, *L'île Enchantée*, produced at Covent Garden (where Sullivan was organist for a time), a symphony, and a cello concerto. The *In Memoriam* and the *Di Ballo* overtures, and numerous songs, including "Orpheus with His Lute."

Sullivan's first comic opera was his setting of F. C. Burnand's *Cox and Box* (1867). An operetta, *The Contrabandista*, also on a libretto by Burnand, was produced in the same year. *Thespis* (1871), the first work in which Sullivan collaborated with W. S.

Gilbert, met with little success when produced at the Gaiety Theatre. It was Richard D'Oyly Carte (q.v.), then manager of the Royalty Theatre, who brought the two men together again in 1875; the result was *Trial by Jury*, which, originally put on as an afterpiece to an Offenbach operetta, won instant popularity and ran for more than a year. Carte thereupon formed the Comedy Opera Company with a view to presenting full-length operettas by Gilbert and Sullivan. The first of these, *The Sorcerer* (1877), was succeeded by *H.M.S. Pinafore* (1878), whose eventual success was phenomenal. It was pirated in the United States, where Carte, together with the author and composer, produced an "official" version in 1879. The U.S. rights for their next operetta, *The Pirates of Penzance*, were secured by a production of this work in New York City, shortly before the London production in 1880. During the run of *Patience* (1881), Carte transferred the production to his newly built Savoy Theatre, where the later operettas were presented. These were *Iolanthe* (1882), *Princess Ida* (1884), *The Mikado* (1885), *Ruddigore* (1887), *The Yeomen of the Guard* (1888), and *The Gondoliers* (1889). In all these Gilbert's satire and verbal ingenuity were matched by Sullivan's unfailing melodiousness, resourceful musicianship, and sense of parody. As a result of this unique partnership their works became almost a national institution.

From time to time, however, Sullivan protested against the artificial nature of Gilbert's plots; this led to a disagreement between them that came to a head when Sullivan supported Carte in a minor business dispute. Sullivan's next opera, *Haddon Hall* (1892), had a libretto by Sydney Grundy, and subsequent collaboration with Gilbert, in *Utopia Limited* (1893) and *The Grand Duke* (1896), did not reach their former standard. Three other operettas were completed by Sullivan: *The Chieftain* (1894), largely an adaptation of *The Contrabandista*; the *Beauty Stone* (1898), with a libretto by A. W. Pinero and J. Comyns Carr; and *The Rose of Persia* (1899), with Basil Hood, who also wrote the libretto for *The Emerald Isle*, left unfinished by Sullivan and completed by Edward German.

Sullivan's more serious and ambitious compositions, such as *The Prodigal Son* (1869), *The Light of the World* (1873), *The Martyr of Antioch* (1880), *The Golden Legend* (1886), and the "romantic opera" *Ivanhoe*, written for the opening of the Royal English Opera House (now the Palace Theatre), built by Carte in 1891, were not maintained in the repertory, though they were acclaimed in their day. He also wrote many hymn tunes, including "Onward, Christian Soldiers"; and his song "The Lost Chord" attained great popularity. In 1876 he accepted the principalship of the National Training School for Music (later the Royal College of Music), which he held for five years; he was active as a conductor, particularly at the Leeds festivals from 1880 to 1888. Despite periods of severe illness he enjoyed a busy social life. Knighted in 1883, he died in London on Nov. 22, 1900, and was buried in St. Paul's Cathedral. See also GILBERT, SIR WILLIAM SCHWENCK.

**SULLIVAN, HARRY STACK** (1892–1949), U.S. psychiatrist who contributed an influential conception of psychiatry as the study of interpersonal relations, was born at Norwich, N.Y., on Feb. 21, 1892. His views quickly became controversial, stimulating much study of the relation between social processes and psychiatric disorder.

Sullivan received his medical degree in 1917 and began his psychiatric work under William A. White at St. Elizabeth's Hospital, Washington, D.C., in 1919; he turned to clinical research at Sheppard and Enoch Pratt Hospital, Towson, Md., from 1923 to 1930. There he developed his formulation of psychiatry and applied it by organizing what became a celebrated special ward for the group treatment of schizophrenic patients. After 1930 he devoted himself to elaborating his theoretical analysis, teaching, helping establish the Washington School of Psychiatry (1936), and writing. Conceiving of anxiety as arising in the infant as a disturbance in relations with the mothering one, he taught that the child develops a self-dynamism that functions to guide behaviour in diminishing anxiety; and that anxiety acts in opposition to tendencies to integrate activities with others. Personality characteristics and the "dynamisms of difficulty"—psychiatric disorders—were seen as interpersonal phenomena. Sullivan explicitly asserted the unique individual personality to be a myth.

Following World War II, Sullivan made energetic efforts to apply psychiatric concepts to international tensions. He died suddenly in Paris, Jan. 14, 1949. His major works include *The Interpersonal Theory of Psychiatry* (1953), *The Psychiatric Interview* (1954), *Clinical Studies in Psychiatry* (1956), and *The Fusion of Psychiatry and Social Science* (1964).

See Patrick Mullanby (ed.), *Contributions of Harry Stack Sullivan: a Symposium of Interpersonal Theory in Psychiatry and Social Science* (1952); Edith Jacobson, "Sullivan's Interpersonal Theory of Psychiatry," *J. Am. Psychoanal. Ass.*, 3:149–156 (1955), a critical review. (A. H. Sn.; X.)

**SULLIVAN, JOHN** (1740–1795), American soldier and political leader who played an important part in the Revolutionary War, was born in Somersworth, N.H., on Feb. 17, 1740. He practised law at Berwick, Mass. (now Maine), and at Durham, N.H., was a member of the New Hampshire Provincial Congress (1774), and also served in the First Continental Congress. In June 1775 he was appointed brigadier general in the Continental Army and aided in the siege of Boston. In April 1776 he was ordered to Canada and, on the death of Maj. Gen. John Thomas, commanded the American troops on their retreat to New York. Superseded in command by Gen. Horatio Gates, Sullivan rejoined Washington's army. He was promoted to major general in August 1776 and took part in the Battle of Long Island, where he was taken prisoner. Exchanged in December, he led the right column of Washington's successful attack at Trenton, and in August 1777 led an unsuccessful night attack against the British and Loyalists on Staten Island. He commanded the American right flank in the Battle of Brandywine and took part in the Battle of Germantown. In 1778 he commanded the troops who were to join with the French fleet under Count d'Estaing in an attack on Newport, but the project failed when d'Estaing withdrew to Boston. Indian raids against colonists in western New York resulted in a retaliatory expedition against them led by Sullivan in 1779; with about 4,000 men, he defeated the Iroquois and their Loyalist allies near present-day Elmira, N.Y., burned their villages, and destroyed their orchards and crops. Thanked by Congress in October 1779 for his conduct in this expedition, he resigned from military service soon afterward because of ill health.

Sullivan was again a delegate to the Continental Congress in 1780–81, and from 1782 to 1786 was attorney general of New Hampshire. He was president of the state in 1786–87 and again in 1789, and in 1786 suppressed an insurrection at Exeter immediately preceding Shays's Rebellion in Massachusetts. He presided over the New Hampshire convention that ratified the federal Constitution in June 1788.

From 1789 until his death at Durham on Jan. 23, 1795, he was

United States district judge in New Hampshire.

**SULLIVAN, JOHN L. (LAWRENCE)** (1858–1918), U.S. professional boxer, known as the "Great John L." and the "Boston Strong Boy." Born on Oct. 15, 1858, at Boston, Mass., Sullivan attended school there and for a time studied at Boston College. At the age of 19 he launched his professional boxing career. Sullivan was supreme at the rough-and-ready style and in 1882 knocked out Paddy Ryan in nine rounds to win the world heavyweight championship. He held the title until Sept. 7, 1892, when James J. Corbett knocked him out in 21 rounds at New Orleans, La. In the last bare-knuckle fight of professional boxing, Sullivan knocked out Jake Kilrain in 1889 in a 75-round battle that lasted 2 hr. 15 min. 25 sec. Sullivan, who had earned more than \$1,000,000 as champion but dissipated it all, later became an advocate of prohibition and gave many lectures on the subject before his death in modest circumstances on Feb. 2, 1918.

(J. P. D.; X.)

**SULLIVAN, LOUIS HENRI** (1856–1924), was one of the pioneers of the modern movement in architecture. Born in Boston, Mass., on Sept. 3, 1856, he studied at the Massachusetts Institute of Technology, Cambridge, and at the École des Beaux-Arts in Paris. He worked as a draftsman in various offices, including those of Frank Furness in Philadelphia, Pa., and William Le Baron Jenney in Chicago, Ill., in 1873–74. A decade later Jenney, an engineering genius, invented the principle of skyscraper construction. (See ARCHITECTURAL ENGINEERING.) Sullivan was much interested in the many structural innovations made in Chicago during the generation after the fire of 1871. Dissatisfied with the widespread imitation of past styles that had prevailed during the preceding century, he sought to create a new architectural style, expressive of the functional problems and engineering advances of his day.

Sullivan's greatest work was done during his partnership with Dankmar Adler (1881–95). During those years the firm designed more than 100 structures. Outstanding were the Auditorium Building (acquired by Roosevelt University), Chicago; the Transportation Building at the Chicago Columbian Exposition of 1893; the Gage Building, Chicago; and two great skyscrapers, the Wainwright Building in St. Louis, Mo., and the Prudential Building in Buffalo, N.Y. In his steel-frame office buildings and skyscrapers Sullivan created designs harmonious with the purpose of the structure and appropriate to the new materials being used. During the years 1887–93 Sullivan was assisted by Frank Lloyd Wright (*q.v.*), who entered the office at 18 and became an ardent disciple of the older man, to whom he always referred as "the Master."

After the dissolution of the partnership with Adler, Sullivan's practice fell off drastically, but the score or more buildings he produced before his death included his masterpiece, the Carson Pirie Scott department store building in Chicago (1899–1904), and a number of fine banks in small midwestern towns, notably National Farmers' Bank (later the Security Bank and Trust Company of Owatonna), Owatonna, Minn.

More influential than his buildings was his philosophy of architectural design, which he set forth in books, magazine articles, and lectures. In these he bitterly attacked the imitation of historic styles—the architectural eclecticism of the 19th and 20th centuries—and called for a modern style expressive of the facts and spirit of the 20th century. Sullivan's theory of "functionalism" is but baldly stated in his slogan "form follows function." He believed that the architectural style of a building should be derived from and expressive of its function and structure. He

BROWN BROTHERS

LOUIS H. SULLIVAN

believed that "each problem contains and suggests its own solution," that each building should have its own identity of beauty and that this must necessarily reflect its origin in present-day conditions, social, technical and spiritual. Another mainspring of Sullivan's thinking was an ardent belief in United States democracy, eloquently expressed in his Whitmanesque prose poetry and basic to his conviction that architecture is a democratic social art. Sullivan's most important published books were *Kindergarten Chats* (1901-02) and *The Autobiography of an Idea* (1924).

Sullivan died in almost complete poverty on April 14, 1924, in Chicago. After his death he came to be recognized, in both the United States and Europe, as one of the great pioneers of modern architecture. In 1943 he was posthumously awarded the gold medal of the American Institute of Architects. In 1956 the centennial of his birth was widely celebrated and an exhibition of his work was prepared at the Art Institute of Chicago for national and international showings. See also MODERN ARCHITECTURE.

See H. Morrison, *Louis Sullivan, Prophet of Modern Architecture* (1935); J. Szarkowski, *The Idea of Louis Sullivan* (1956). (H. M.)

**SULLY, MAXIMILIEN DE BÉTHUNE**, DUC DE (1559-1641), French statesman who, as the trusted minister of Henry IV, substantially contributed to the rehabilitation of the state after the Wars of Religion. He was born in the château of Rosny, near Mantes, on Dec. 13, 1559, the son of François de Béthune, baron de Rosny (1532-75). Brought up as a Huguenot, he was early sent to the court of Henry of Navarre (the future Henry IV of France), who took him to Paris in 1572. A student at the Collège de Bourgogne there, he escaped death in the Massacre of St. Bartholomew's Day by carrying a Catholic Book of Hours under his arm. In the civil war of 1575-76, Rosny, as he was called, served in Henry's forces; but in 1580 he went to the Netherlands, in the hope of recovering ancestral lands there. Disappointed, he went back to Henry of Navarre in Guienne. In 1583 he was Henry's special agent in Paris. In 1584 he married a rich heiress, Anne de Courtenvaux (d. 1589). On the renewal of civil war (1585) he rejoined Henry of Navarre. In the Battle of Ivry (1590), during Henry's struggle for the French crown, Rosny was badly wounded. He was in favour of Henry's conversion to Roman Catholicism but refused to change his own religion. He helped arrange Henry's marriage to Marie de Médicis (1600) and to negotiate peace with Savoy (1601); and in 1603 he was ambassador extraordinary to James I of England.

Rosny, who became a member of the king's Council of Finance in 1596, seems to have been sole superintendent of finances by 1598. In this capacity, though he was not strictly an economist, he had the practical sense and the resolution to discern and to impose the most efficacious measures. He authorized the free export of grain and wine; reduced the legal rate of interest on loans from 8½ to 6½%; set up a special court to try cases of speculation; stopped various abuses of tax collecting, including the raising of money by provincial governors on their own authority; and abolished some superfluous public offices. It was he, moreover, who in 1604 sponsored the adoption of the system of the "annual right" or *droit annuel*, which assured the state of a predictable revenue, at the cost of making offices in fact hereditary: under this system, officeholders by paying annually one-sixtieth of the sum that they had originally paid for their office could secure the right to transfer it as they might see fit, whereas previously any transfer that they might have made, by sale or by bequest, could be annulled if they died within 40 days of making it. Altogether, through honest and rigorous conduct of the finances, an average of 1,000,000 livres a year was saved between 1600 and 1610.

The chancellor Pomponne de Bellièvre, who stood for the old tradition of the French monarchy (with the various councils and the *parlements* playing a considerable role in public affairs), was eventually eclipsed by Rosny, who was indeed "the king's man" and who subordinated private and particular interests to the authority of the state. Rosny's loyalty was copiously rewarded. He was appointed grand commissioner for highways and public works in 1597; superintendent of fortifications and grand master of the artillery in 1599; governor of Mantes and of Jargeau, captain general of the queen's *gens d'armes*, and governor of the

Bastille in 1602; and governor of Poitou in 1603. Finally, in 1603 he was created duc de Sully and a peer of France.

For the internal economy, Sully encouraged agriculture and stock raising, urged the free circulation of produce, checked the destruction of the forests, promoted road building and the draining of marshland, and planned a great canal system (the Briare Canal was actually started). He did little for industry, except to establish some silk factories, on which the king himself insisted and he was unsympathetic to the king's colonial policy. He strengthened the military establishment and directed the construction of frontier defense works.

Sully's political role came practically to an end with the assassination of Henry IV on May 14, 1610. Though Marie de Médicis, as regent for Louis XIII, at first retained him in her council, his colleagues were impatient of his domineering leadership, and on Jan. 26, 1611, the queen accepted his resignation. He then retired into private life. In 1634 he was created a marshal of France. He died at Villebon on Dec. 22, 1641.

Sully's curious and lengthy *Mémoires*, otherwise known as the *Économies royales* (1638; numerous editions down to 1837; modern ed. by L. R. Lefèvre, 1942), are remarkable for their often reprinted account of the "Great Design," which he attributes to Henry IV—a European confederation or "Christian Republic" to be established after the defeat of Austria and Spain.

**BIBLIOGRAPHY.**—Apart from H. Carré, *Sully* (1932), and H. Poincaré, *Sully et sa grande passion* (1942), the best works are those listed under HENRY IV; see especially R. Mousnier, *La Vérité des offices ...* (1946) for the new light that it casts. For the "Great Design," see C. Pflster article in the *Revue historique*, vol. 54 and 56 (1894); and A. Puhar, *Les Projets d'organisation européenne d'après le Grand Dessein* (1954). (V. L. T.)

**SULLY, THOMAS** (1783-1872), U.S. painter, one of the best early American portrait painters, was born at Horncastle, Eng., on June 8 (or 19), 1783, of actor parents. They moved to the United States when Sully was nine years old, settling at Charleston, S.C. He was a pupil of Gilbert Stuart in Boston, and in 1809 he entered the studio of Benjamin West in London. After 1810 he made Philadelphia his home, but in 1837 again visited London, where he painted a full-length portrait of Queen Victoria for the St. George's Society of Philadelphia. He died in Philadelphia on Nov. 5, 1872. Though Sully left about 500 subject pictures, he is best known for portraits. Among his 2,000 portraits are those of Stephen Decatur (City Hall, New York); the actor George Frederick Cooke as Richard III, and Lafayette (both in the Pennsylvania Academy of the Fine Arts, Philadelphia); and Thomas Jefferson (U.S. Military Academy, West Point, N.Y.). Many others are in galleries throughout the U.S.

**SULLY PRUDHOMME** (real name RENÉ FRANÇOIS ARMAND PRUDHOMME) (1839-1907), French poet connected with the Parnassian school, winner of the Nobel Prize for Literature in 1901, was born in Paris, March 16, 1839. Throughout his life he suffered from a feeling of loneliness. Ophthalmia prevented him from taking up scientific studies, and he worked as a clerk in Paris (1860). His first published poem, "L'Art," appeared in *La Revue nationale et étrangère* (1863). In 1864 he met Leconte de Lisle and contributed to *Le Parnasse contemporain* (1866, 1871, and 1876). Like the Parnassians, he concentrated on technique but differed in expressing personal feelings—fleeting joys and sorrows in *Stances et poèmes* (1865) and *Les Épreuves* (1866), craving for affection in *Les Solitudes* (1869) and *Les Vaines tendresses* (1875). This sentimental verse, of which "Le Vase brisé" is typical, was widely acclaimed, whereas little interest was aroused by his attempts to create a new type of philosophic and scientific poetry—*Les Destins* (1872), *Le Zénith* (1876), *La Justice* (1878), and *Le Bonheur* (1888). His last works were in prose—*Testament poétique* (1901) and *La Vraie Religion selon Pascal* (1905). In 1882 he was elected to the Académie Française. He died at Châtenay, near Paris, Sept. 7, 1907.

**SULMAN, HENRY LIVINGSTONE** (1861-1940), English metallurgist, one of the originators of the froth flotation process.

cess for concentrating ores preliminary to the extraction of metal from them, was born in London on Jan. 15, 1861. From 1878 to 1881 he studied chemistry at University College, London, gaining a number of medals and other awards. After graduation he served as chemist or manager of various chemical plants in Bristol and London and subsequently engaged in consulting work. In 1898 he entered into partnership with H. F. K. Picard as metallurgical consultants in the City of London, work that involved travel to South Africa, Australia, Malaya, Japan, and Canada. He was the inventor, or co-inventor, of several processes for the extraction of gold, including treatment with bromocyanide. Later, and in conjunction with his partner Picard, he introduced the froth flotation process. The Institution of Mining and Metallurgy, of which he was president 1911-12, awarded him its Gold Medal in 1919. He also received the Gold Medal and premium of the Consolidated Gold Fields of South Africa in 1920. He died at Croydon, Surrey, on Jan. 31, 1940. See also METALLURGY: *Ores and Ore Treatment*. (C. W. D.)

**SULMONA**, a town in L'Aquila Province, Abruzzi e Molise, Italy, 30 mi. (48 km.) SW of Pescara. Pop. (1961) 21,518. Remains include an aqueduct (1250) that supplied water to a 15th-century fountain. The Palazzo dell'Annunziata, founded in 1320, has a facade in both Gothic and Baroque styles. The 13th-century Church of S. Francesco della Scarpa was damaged by earthquakes but retains an imposing Romanesque portal; Sta. Maria della Tomba (15th century) has a Romanesque-Abruzzese front and a rose window; the Palazzo Tabassi has a fine 15th-century Gothic double window. There are collections of ancient marble and medieval Baroque jewelry in the museum. The poet Ovid was born in Sulmona in 43 B.C.; part of his villa still remains. Pope Innocent VII was also a native of the town. Sulmona is a railway junction on the Rome-Pescara line. Manufactures include confectionery (sugared almonds) and liqueurs, and copper and wrought-iron work; trade in agricultural products is important. (M. T. A. N.)

**SULPHUR**. For a description of this element and its commercially important acid, see SULFUR; SULFURIC ACID.

**SULPICIUS RUFUS, PUBLIUS** (c. 124-88 B.C.), outstanding Roman orator and politician who supported the reforms of his friend the younger M. Livius Drusus (91 B.C.) and inherited his policy of generous concessions to the Italian allies. Though he renounced his patrician status to become a tribune of the plebs, he had shown, by prosecuting the tribune Gaius Norbanus (q.v.) for treason c. 94, that his political attitude was moderate, and he had a subordinate command for at least one year (89) in the Social War against the allies (*socii*). As tribune in 88 he introduced several laws: (1) to unseat all senators who were more than 2,000 denarii in debt; (2) to recall all men exiled under the *Lex Varia* of 90 B.C. (a measure that he himself had opposed earlier); (3) to transfer the command in the war against Mithradates from Sulla, the Senate's nominee, to Marius; and (4) to distribute freedmen and the newly enfranchised Italians among the 35 tribes (so as to make their voting power effective). Sulpicius' chief aim was probably championship of the new Italian citizens, but to implement this he needed wide support: hence his other measures, which would secure for him the backing of the people, of Marius, and of the equites. This bold challenge to the Senate led to violence, and Sulpicius is said to have organized a group of 600 young equites and a larger bodyguard of 3,000 armed men. The consuls, Sulla and Q. Pompeius Rufus, declared some form of cessation of public business (perhaps a *justitium*), which Sulpicius denounced as illegal. Disturbances followed in the Forum, and Sulla was forced to call off the *justitium*; he then joined his army in Campania. At Rome Sulpicius' measures were carried. Sulla then marched on Rome and won the city. Marius and Sulpicius fled and were declared outlaws, and Sulpicius was caught and killed at Lavinium. His laws were declared invalid, as passed "by force." Sulpicius' policy is obscure, but he may well have been a liberal optimist, whose championship of the Italians led his enemies to depict him as a revolutionary demagogue rather than as a moderate reformer forced by circumstances to go to greater lengths than he probably wished. He was an outstanding orator, though his

speeches are lost, and was much admired by Cicero, who made him a speaker in his *De oratore*. (H. H. Sd.)

**SULPICIUS RUFUS, SERVIUS** (c. 106-43 B.C.), Roman jurist, who left nearly 180 treatises on law and is often quoted in the *Digest* of Justinian, although direct extracts from his works are not found. He studied rhetoric with Cicero and went with him to study in Rhodes in 78 B.C. Deciding that he would never be a first-class orator, he gave up rhetoric for law. In 63 he was a candidate for the consulship of 62 but was defeated by L. Licinius Murena, whom he subsequently accused of bribery; Cicero successfully defended Murena. In 51 Sulpicius became consul. In the civil war, after considerable hesitation, he threw in his lot with Julius Caesar, who made him proconsul of Achaia in 46. He died in 43 while on a mission from the Senate to Mark Antony at Mutina. He was accorded a public funeral, and a statue was erected to his memory in front of the Rostra.

Two letters from Sulpicius to Cicero are preserved (Cicero, *Ad familiares*, iv, 5 and 12); the first is his famous letter of consolation on the death of Cicero's daughter Tullia. Quintilian mentions three orations by Sulpicius (now lost); one of these was the speech against Murena, another *Pro* (or *Contra*) *Aufidia*, of whom nothing is known. He is also said to have been a writer of erotic poems, though this may refer to his son. The poetess Sulpicia was probably Sulpicius' granddaughter.

**SULPICIUS SEVERUS** (fl. c. A.D. 400), a Christian ascetic, one of the chief authorities for Gallo-Roman history of his own times and the most graceful writer of the age, was born in Aquitaine (southwestern France) of good family not earlier than 353. Trained for the bar in the best period of Gaulish rhetoric, he devoted himself after the early death of his wife to local church building and to the life of a literary recluse in Aquitaine, forwarding the interests of the church in the West, and especially the ascetic monasticism recently introduced into Gaul. To the friendship and generosity of his mother-in-law, Bassula, in Trier he owed his pecuniary independence and doubtless much of his knowledge of current affairs. The biographer Gennadius (c. 500) refers to him as a priest whose orthodoxy was suspect, and he was not in good relations with the Gaulish bishops; but the references to him by St. Augustine and St. Jerome are friendly, and 13 extant letters are addressed to him by his friend St. Paulinus of Nola, one of the choicest Christian spirits of the age. Severus died probably in the first quarter of the 5th century.

Severus' most famous work, the *Vita S. Martini*, was in first draft before the death of St. Martin in 397; but supplementary matter relating to Martin is added in all his subsequent writings, including three authentic surviving letters. In 400 he wrote and c. 402-404 published his *Chronica* ("Sacred Histories") in two books, from the creation to his own time, but omitting the Gospels. It is unusually readable, and the latter portion is a valuable contemporary document, especially for the tragic history of the Priscillianists (see PRISCILLIAN). The *Dialogi*, which appeared in 404, are a literary masterpiece in which the relative merits of Martin's monastery are debated by one of its inmates with a traveler newly returned to Aquitaine from the ascetics of the North African desert, while Severus presides and prompts the speakers.

**SULTANPUR** (formerly KUSAPURA or KUSHBHAWANPUR), a town of Uttar Pradesh, India, and the headquarters of the district of the same name, is on the Gumti River, 83 mi. (134 km.) SE of Lucknow. Pop. (1961) 26,081. Sultanpur is an ancient town, although little is known about its origins. Destroyed and rebuilt several times, it passed into the hands of the sultans, possibly in the 12th century. The Muslim town was finally razed to the ground in 1857. The present town grew as a military settlement during the early British occupation.

SULTANPUR DISTRICT (area 1,713 sq.mi. [4,437 sq.km.]; pop.

[1961] 1,412,984) forms a part of the Ganges-Ghaghra Doab west, traversed by the Gumti and its tributary, the Sai. The surface in general is level, except for some patches of ravines and *usar* lands. The chief crops are rice, wheat, barley, and millets. There is a degree college at Amethi affiliated to Agra University.

(R. L. Sr.)

**SULU**, a province and archipelago in the Philippines extending about 170 mi. (274 km.) SW from the southwestern tip of Mindanao. Its area of 1,087 sq.mi. (2,815 sq.km.) is divided into hundreds of islands, some volcanic and some coral, of which the most important are Jolo, Tawi Tawi, Sanga Sanga, Sibutu, Siasi, and Cagayan Sulu. The 1960 provincial population of 326,898 was about 95% Muslim. These Muslim tribes, known as Moros, historically were fiercely independent (*see* Moro). During the Spanish occupation of the Philippines a troop garrison was stationed at the town of Jolo but Spanish rule never extended far beyond the fort. During the early period of U.S. rule, which began in 1899, several battles were fought against the Moros. The archipelago became part of Moro Province (1903) and civil government was established in 1914. On March 11, 1915, the reigning sultan of Sulu agreed to abdicate his rights of sovereignty and to retain only his right to be head of the Islamic sect. Following this agreement sporadic fighting continued between government forces and outlaw bands. A treaty signed April 1940 abolished the sultanate, and Sulu became part of the Commonwealth, later the Republic, of the Philippines.

Cassava, coconuts, and rice are the main agricultural products, but rice is not produced in sufficient quantity and some must be imported. Fishing and gathering seashells (for the manufacture of buttons) are important activities. The Turtle Islands are famous as a source of turtle shells and eggs. Considerable illegal trade is carried on between Sulu and Borneo. The capital and chief port and trading centre is the town of Jolo on Jolo Island.

(R. E. HE.)

**SULU SEA**, a large, very deep interisland sea, located between the southwestern Philippine Islands and northeastern Borneo. About 350 mi. (563 km.) from north to south, 425 mi. (684 km.) in east to west dimension, and 135,000 sq.mi. (349,650 sq.km.) in area, the Sulu Sea is enclosed by various islands of the Philippines: Palawan on the west and northwest, Dalanganem and Cuyo Islands on the north, Panay and Negros on the east, Mindanao and the Sulu archipelago on the southeast, and Sabah on the southwest. The sea occupies a downfaulted block, in some places almost 3,000 fathoms (18,000 ft. [5,486 m.]) deep. The edges of this enclosed basin are seen in the bordering islands, particularly in the northeast-southwest orientation of Palawan and the Sulu archipelago. The sea is bisected by another northeast-southwest fracture line which is evidenced by the coral atolls of the Cagayan Islands, the Tubbataha reefs, and the volcanic cones of the Cagayan Sulu group. The sheltered sea is extensively used for interisland trade. Fishing is an important occupation and marine products include pearls, pearl shells, *bêche-de-mer*, shark fins, and turtle eggs. Copra, timber, and forest products of the surrounding islands provide the other commercial activities of the area.

The Sulu Sea was long the stronghold of the fierce Moro pirates of the Sulu archipelago, who raided shipping as far away as Malaya. Punitive campaigns, started by the Spanish in the mid-19th century and terminated by U.S. troops in 1906, broke the power of the Muslim Moros and brought peace to the area. (L. A. P. G.)

**SUMAC**, the popular name for shrubs and small trees of the genus *Rhus* (family Anacardiaceae) with perhaps 50 species in southern Europe, Asia, and eastern North America. They have a resinous, milky sap that hardens in the air; a few staghorn branches; alternate, pinnate leaves; terminal clusters of small flowers with parts in fives; and small, one-seeded, hairy, red fruits. Closely related to and often included in *Rhus* is the genus *Schmalzia* with about 30 species of many-branched shrubs with spikelike clusters of flowers and fruit and variously compound or simple, deciduous, or evergreen leaves. The distribution of *Schmalzia* centres in Mexico.

The name sumac is given also to the commercial preparation of

ROCHE

SMOOTH SUMAC (*RHUS GLABRA*)

the dried and ground leaves of the Sicilian or tanners' sumac (*R. coriaria*) of southern Europe long used in making leather. Several of the eastern North American species also were used in tanning. Among the most attractive North American shrubs are the staghorn sumac (*R. typhina*), sometimes a tree 30 ft. (9 m.) high, and the smooth sumac (*R. glabra*), sometimes 20 ft. high, both of which in autumn display highly coloured fruit and foliage. The dwarf or shining sumac (*R. copallina*) is a small shrub in the north and a tree 30 ft. (9 m.) high in the south. Best known in *Schmalzia* is the aromatic sumac (*S. crenata*), 3 to 8 ft. (0.9 to 2.4 m.) high, with pleasant-scented foliage, which occurs in the eastern U.S., and its western counterpart, the skunkbush or squawbush (*S. trilobata*, perhaps better treated as a subspecies of *S. crenata*), with ill-scented foliage, found from Illinois to Oregon and southward. The mahogany sumac, or sourberry (*S. integrifolia*), and the sugarbush (*S. ovata*) are elegant shrubs of southern California.

The laurel sumac of the same area is sometimes placed in another segregate genus, *Malosma* (*M. laurina*).

The swamp-dwelling poison sumac (*Toxicodendron vernix*) is closely related to poison ivy (*q.v.*) and poison oak. Poison sumac can be distinguished from other sumacs by its persistent white or grayish fruits.

In addition to their value in tanning, sumacs were used by the American Indians as sources of orange dyes, medicines, fuel, twigs for basket-weaving (*S. trilobata*), and fruit for cool drinks in summer and hot drinks, with maple sugar, in winter. *R. chinensis* of eastern Asia and *R. typhina* and *R. glabra*, especially the narrow-leaved varieties, are planted for their ornamental foliage. Sumacs are valuable as sand binders, game cover, and pioneers in the revegetation of denuded areas.

(R. F. TH.)

**SUMATRA** (SUMATERA), an island in the Republic of Indonesia lying between 5°39' N and 5°57' S, so that the Equator divides it into two nearly equal parts. Sumatra is the westernmost and, after Borneo, the second largest of the Greater Sunda Islands of the Malay Archipelago. It is separated in the northeast from the Malay Peninsula by the Strait of Malacca and in the south from Java by the Sunda Strait. It is 1,069 mi. (1,722 km.) long, and its greatest width is 324 mi. (521 km.). With its adjacent islands, Sumatra has an area of 182,859 sq.mi. (473,600 sq.km.). In 1961 the population was 15,739,363 (about one-sixth of the Indonesian total of 97,018,829).

## PHYSICAL GEOGRAPHY

**Relief and Drainage.**—Sumatra consists of a high mountain chain which runs along the western coast, descending eastward to a huge tract of flat, alluvial land, drained by many large rivers and their scores of tributaries. Its mountain chain is part of the great mountain system which occurs in Lower Burma and continues via Prepara, the Great Coco Islands, the Andaman Islands, and the Nicobar Islands to Sumatra and then swings east through Java and the Lesser Sunda Islands to the Moluccas. The Sumatran chain, running northwest-southeast through the island, extends for a distance of more than 1,000 mi. (1,609 km.) and contains numerous volcanic peaks up to more than 12,000 ft. (3,658 m.). The whole system, known as the Pegunungan Barisan ("Parade of Mountains"), consists in general of two or more folded chains running parallel to each other, with a valley between, which is broken up into separate sections by the intrusion of volcanic massifs. Along this valley lies a string of mountain lakes, from

south to north—Ranau, Kerintji, Singkarak, Manindjau, and Toba. By far the largest of these is Lake Toba, which is 56 mi. (90 km.) long and 19 mi. (30 km.) wide, of great depth, and has a large island, Samosir.

The line of volcanic peaks stretches through Sumatra from Abongabong (9,892 ft. [3,015 m.]) and the mountains of Atjeh to the islet of Krakatau (*q.v.*) at the southern end of the island. It includes Leuser (Loser; 11,548 ft. [3,520 m.]), Talakmau (Mt. Ophir; 9,554 ft. [2,912 m.]), Kerintji (Indrapura, 12,483 ft. [3,805 m.]), the highest point in Sumatra, and Dempo (10,364 ft. [3,159 m.]). In all, 90 volcanoes have been counted, 12 active.

Sumatra, like Java and Borneo, is formed largely of strata of the Tertiary Period, although it contains also two schistose formations, one of which is pre-Carboniferous. The Tertiary series are more complete than in Java; the volcanoes, so characteristic of the whole archipelago, were formed during the Quaternary Period. The western mountain system is composed largely of Archean rocks, with occasional longitudinal bands of Jurassic and Cretaceous rocks. The whole ridge is metalliferous, and erosion of the ranges exposes their mineral contents. The crystalline rocks (including granites and basalts) are of various geological ages; they are exposed by denudation, or pushed through by intrusion. Extensive petroleum deposits occur in the Tertiary rocks underlying the eastern lowland.

The river system of Sumatra is extensive and of great value to the country. On the west coast, where the mountains approach the sea, the rivers run in valleys with a steep slope, have a very short lower course, and are unnavigable, except near the mouth in the case of a few. The eastern rivers (often impeded by silt) run through alluvial plains, have extensive drainage areas, and form the principal and often the only means of communication. The important rivers lie south of 3° N: the Asahan, which drains Lake Toba, navigable by steamers for a portion of its length; the Panai (Bila and Barumun), with a very wide mouth; the Rokan, about 140 mi. (225 km.) long and flowing into the Strait of Malacca through a wide, muddy estuary, navigable for 70 mi. (113 km.) inland; the Siak, with the port of Pekanbaru 90 mi. (145 km.) upstream; the Kampar and the Inderagiri, both partly navigable for ocean steamers; the Hari, the longest river of Sumatra, having a maximum navigability of 300 mi. (483 km.); and the Musi (*q.v.*), on which oceangoing vessels can reach Palembang, 56 mi. (90 km.) upstream, while steam launches and motorboats are able to go farther inland.

On the west coast there are small semicircular bays but few large indentations, immunity from the southwest monsoon being provided for harbours only between Tapanuli Bay and Indrapura. The north coast has precipitous cliffs crowned with dense vegetation in some parts; in other sections there are sandy beaches and well-cultivated plains, while the Bay of Uleelheue gives shelter for shipping. The south coast consists, mainly, of two large indentations, Lampung Bay and Semangka Bay. The eastern shore of Lampung Bay is mountainous and little indented, the western much cut up; the centre of the bay has a good harbour (Telukbetung). Semangka Bay has a mountainous coastline, with little indentation. The whole of the east coast is formed of morasses and sandbanks, which break up into innumerable islands, large and small, particularly about the central portion; and the coastline is deeply indented in many places and very irregular. The indentations are not permanent, the coast is constantly advancing, and it is difficult to establish practicable ports or landing places.

Sumatra has a chain of islands off the west coast which arise from the edge of the submarine platform and serve as a kind of outer barrier. They have an aggregate area of 5,769 sq. mi. (14,941 sq. km.). Several are densely populated, and some are of considerable size; most have rocky, reef-bound coasts, dangerous of approach. Between south Sumatra and Malaya, athwart the entrance to the Strait of Malacca, lie the innumerable islands of the Riuw Archipelago (*q.v.*).

**Climate.**—The climate of Sumatra resembles that of Java and is hot and extremely moist, but in most eastern coastal districts and often for many miles inland the heat is tempered by cooling land and sea breezes, the wind generally being northeast by day

and southwest by night throughout the year. The wind system of northern Sumatra differs from that of the greater part of Indonesia, the northeast monsoon blowing from December to March, and the southwest monsoon from May to October. During the southwest monsoon strong squalls from the northwest, known as Sumatras, which are accompanied by thunder, lightning, and rain, blow in the Strait of Malacca; they have been known also to occur during the northeast monsoon. On the west coast the influence of the northeast and southwest monsoons is felt as far south as 4° N. Between 4° N and 2° N there is a region of calms and light variable winds, which have a westerly tendency from March to November, when the northwest monsoon is blowing along the remainder of the west coast (*i.e.*, from 2° N to 5°57' S), and an easterly tendency from May to September, the period of the southeast monsoon on the west coast. Southern Sumatra has the highest temperatures, and the mean annual temperature for the lowlands is about 26.6° C (80° F). At Toba, in the Batak country (3,772 ft. [1,150 m.]), this is 21° C (69.6° F), and higher altitudes show a corresponding reduction. On the whole, temperature in Sumatra is slightly higher than in Java. March, April, and May are the hottest months; January and February the coolest, but the difference does not exceed 2° F. The different wind distribution causes a variation of the seasons. Thus in northern Sumatra October is the wettest month and February and March are the driest, while elsewhere the wettest months are December, January, and February, and from July to September is the dry period. Accordingly, the rainfall varies considerably. The annual average rainfall for northern Sumatra is 95 in. (2,413 mm.), for eastern Sumatra 106 in. (2,692 mm.), and for western Sumatra 122 in. (3,099 mm.). The west monsoon gives the heavier rainfall, and the fall is accentuated in western Sumatra by the high mountains.

**Vegetation.**—The vegetation of Sumatra bears a strong resemblance to that of India and of the Malay Peninsula in the northern part of the island and to that of Java in the southern, but it has also many varieties distinct from either, and not only different varieties but different genera from those of Java. The pine, *Pinus merkusii*, in the mountains of the north is not found elsewhere in the Malay Archipelago but occurs as far south as the Equator. One of the most striking flowers is the huge parasitic monster flower, *Rafflesia*, with blossoms up to three feet across, growing on big lianas on the ground in the forests. There are immense areas of savanna country, covered with coarse grasses which stifle other forms of vegetation and give shelter to hordes of wild animals. These tracts occur as low as within 700 ft. (200 m.) of sea level. Myrtles, bamboo, rhododendrons, moss-loving orchids, and palms are common. There are zones of vegetation differing with altitude, but the general tendency is for all forms to grow at a lower level than is the case in Java. The Sumatran forest begins at a height of from 300 to 400 ft. (90–120 m.) and extends to all but the highest mountain peaks, giving a wealth of vegetation that produces very beautiful mountain scenery. The forests contain the finest timber-producing woods in the archipelago; there is not only a great variety of trees, but they possess both stature and beauty. Deciduous trees such as the oak, chestnut, etc., grow on lower slopes than in Java; and apart from ebony, ironwood, camphorwood, and sandalwood there are also many species of resin and wild rubber-producing trees.

**Animal Life.**—Notwithstanding the proximity of the island to Java the fauna of Sumatra shows a greater resemblance to that of Borneo than to that of Java, this being particularly noticeable as regards the fauna of the east coast of Sumatra (that of the west coast and of the islands adjacent is more allied to the Javanese fauna). This striking difference in species between the fauna of Sumatra and Java led A. R. Wallace to assert that the first severance of Sumatra from Java is very ancient; that since the epoch of the first (volcanic) disturbance several distinct elevations and depressions may have taken place, the islands having perhaps been more than once joined with each other or with the mainland (of Asia) and again separated; and that successive waves of immigration may thus have modified the fauna and led to those anomalies in distribution which are so difficult to account for by any single operation of elevation or submergence.

The orangutan, common to Sumatra (in the northeast) and Borneo, is unknown in Java; the siamang is found in Sumatra and in the Malay Peninsula but not in Borneo or Java; there are ape species common to Borneo and Sumatra, also the elephant (introduced into Borneo), tapir (indigenous also in the Malay Peninsula), and Malayan bear, all of which are unknown in Java, though, on the other hand, Sumatra shares the tiger with Java, while it is unknown in Borneo. The one-horned rhinoceros of Java is known also in Sumatra, which shares a two-horned variety with Borneo, but the rhinoceros is now dying out. The Sumatran fauna also includes among primates the gibbon, the banded leaf monkey and the pig-tailed macaque, both common to Borneo also; the silvered leaf monkey and crab-eating macaque, common to Borneo and Java; the slow loris; tree shrews; and the flying lemur, bats, flying squirrels, rats, and mice; the sambar and the serow; wild dog; wild boar; and civet cat.

There is no genus of birds peculiar to Sumatra, but there are a few species and many subspecies. The birdlife is very similar to that of the Malay Peninsula; in the extreme south a few Javanese forms are found. Among birds found in Sumatra but not in Java are the great Argus pheasant, the fireback and other pheasants, and various partridges, the little Malay parrot, the helmeted hornbill, and the red-breasted bee-eater. Other Sumatran birds include woodpeckers, pigeons, and trogons. Insects, which also show a marked difference from those of Java, comprise many beautiful butterflies; the *Kallima* butterfly imitates the leaf of a certain plant so closely as to secure itself from the attacks of enemies. Lizards, large and small, frogs, tortoises, and turtles abound; crocodiles frequent the mouths of rivers and are also found upstream; there are many varieties of poisonous snakes; the rocks around the coast yield many kinds of shellfish; and the sea, ponds, and rivers, numerous sorts of edible fishes. (E. E. L.; J. O. M. B.)

### THE PEOPLE

The inhabitants of Sumatra belong to the Oceanic or southern branch of the Mongoloid race, and to the Malayo-Polynesian linguistic family. They form several groups, each with its own language and distinctive cultural traits. In the lowlands of northwest Sumatra live the Achinese (*q.v.*), who are intensely devoted to Islam. Marriage is matrilineal and the position of the woman is high. The Gajo (*q.v.*) and Alas peoples live in the mountainous north-central portion between the Achinese and Bataks. They are Muslim, with a substratum of animism, and dwell in well-built stilt houses of wood, in small scattered villages. Their chief crop is rice; they rear cattle and horses and collect forest products. The Batak (*q.v.*) inhabit the mountainous region around and south of Lake Toba. Nearly one-third are Muslim, well over one-third Christian, and the rest animist. The Batak possess a written language of their own; they build large houses on piles, with horned roofs, each house occupied by many families, and have rice barns and a communal hall. The houses are beautifully decorated, the Batak being clever craftsmen in wood, ivory, and copper. They are also good agriculturists (rice cultivation, wet and dry, being their chief occupation), and they raise horses, cattle, buffalo, and pigs. They have keen minds and great energy; most of them are literate and many have become traders and shopkeepers, teachers, and even doctors.

South of the Batak, in the Padang Highlands and vicinity, are the Menangkabau (*q.v.*), the largest ethnic group in Sumatra. Although converted to Islam, the Menangkabau have retained their ancient custom of the matrilineate (*i.e.*, descent and inheritance through the female line). A wife remains with her maternal relatives after marriage, and the husband, having no home of his own, only visits his wife and resides in his mother's house; names, privileges, and property derive from the mother's side; the eldest man of the elder female line is termed *mamak* and is the keeper of all the family possessions. Houses, raised high above the ground, are very ornate, with horned ridge poles and finely carved wooden fronts, sometimes painted. Several families bearing the same patronymic live in the same house; and several houses, their rice barns, a communal house, a mosque, a school, an inn, and a market form a village. The Menangkabau are skilful farmers (as evi-

denced by their terraced mountain slopes), excellent wood carvers, metalworkers, and weavers. Whether it was to escape the limitations of highland agriculture, or those of matriarchy, more men of the Menangkabau have settled in other areas and achieved much, helped by Western education which the Menangkabau accepted several generations ago.

The Lampong (*q.v.*) languages are spoken south of the Menangkabau, along the west side of Sumatra to its southern tip. The people of this linguistic group, such as the Redjang and Lebong in the mountains and the Lampong proper in the southern lowlands, have all undergone Hindu influence. In addition to rice for food, pepper and coffee are grown for export. Since the 1930s there has been considerable resettlement of Javanese in the southern lowlands (see *Population*, below).

On the east coast of Sumatra live the Malays (*Melayu*), essentially a coastal and riverine people (see also *MALAY*). In the north, next to the Achinese, they occupy a narrow strip in front of the upland Batak, and in the wide southern plains they inhabit a broad territory. Their seafaring has carried them to many islands, and they have settled not only the adjacent islands but also the coastal regions of west Malaya and of Kalimantan (Indonesian Borneo). Their speech became the lingua franca of the archipelago and now forms the basis for the Indonesian national language. Generally speaking, they are indifferent farmers but good fishermen. Their houses, simple in style, are rectangular and built on piles, for single families. All are Muslims. Among them, deep in the forests, live small bands of the shy nomadic Kubu, their frizzled hair and dark skin denoting Negroid affinities. They live by gathering, hunting, and fishing. For the western islanders see *SIMEULUE*; *NIAS*; *MENTAWAI*. (J. O. M. B.)

### PREHISTORY

The earliest prehistoric remains recorded from Sumatra are Mesolithic, the shell heaps on the north coast being the best known of them. These are accumulations of seashells, evidently food remains of a coastal people, though retreat of the sea has left them 6 to 9 mi. (10 to 14 km.) inland. Numerous stone hand axes have been found in them of a peculiar "uniface" type: oval pebbles worked only on one side. Other remains include red hematite and some rather fragmentary human remains. A quite distinct Mesolithic culture, represented by small flakes and blades of obsidian, has been found around Lake Kerintji and near Palembang.

Evidence that Sumatra was inhabited by the carriers of the Neolithic Quadrangular Adze culture exists but is rather scanty. Of the ensuing Megalithic culture, remains are impressive, and those at Pasemah were investigated in detail in 1931 by A. N. J. van der Hoop. Most remarkable of these remains are large stone images of very dynamic style, representing such subjects as helmeted warriors, people riding on elephants and buffalo, and men fighting a serpent. Upright stones, dolmens, and stone troughs are also among the remains, which are probably contemporaneous with the Indochinese Dong-son culture and so dated approximately at the few centuries immediately preceding the Christian era. (M. W. F. T.)

### HISTORY

**Indian Influence.**—Trade between India and China, through the Strait of Malacca, developed about 2,000 years ago, and thus Sumatra became known to the outer world. Thereafter its relations with India were close, and expressed themselves in the deep impact of Indian culture; those with China, although economically and politically significant, had little if any direct cultural effect. Knowledge of Sumatra's early history is very fragmentary, since it rests on a few Chinese reports and some local inscriptions. Moreover, there is uncertainty whether the foreign sources using "Yawa" or some such name refer to Java or Sumatra.

Chinese reports of the early 5th century leave no doubt about the existence of a hinduized aristocracy. Sanskrit and the Pali script of south India were used, and Buddhism was at the time gaining ascendancy over the Shivaistic rites of Brahmanism. In the 7th century there were at least two hinduized kingdoms in Sumatra. The northern one, *Melayu*, had its capital on the

Baru River at the site of modern Jambi (Djambi). It was overshadowed, and before long conquered, by Sri Vijaya, with its capital on the Musi River at Palembang. Palembang was a centre of Buddhist scholarship, and a meeting place for Chinese pilgrims (among them I-tsing, c. A.D. 680) going to or coming from India. In the 8th century Sri Vijaya came under a branch of the Shailendra (Cailendra) dynasty, well known in the history of Java (q.v.), but the Sumatran rulers appear soon to have become independent of Java. At first, relations between the two houses were good, but as Sri Vijaya rose to be a mighty empire friction developed. The Sumatran kingdom came to dominate not only most of Sumatra but also Malaya, including the Isthmus of Kra, thus controlling the sea trade through the straits as well as the land passage across the neck of the peninsula. Its influence reached to southern Indochina as well as to Ceylon. It reached the zenith of its power toward the end of the 10th century. It not only beat off an attack from the East Javanese kingdom of Mataram but counterattacked, killing the king of Mataram and destroying its capital (1006).

In the early 11th century there were several wars for naval hegemony between Sri Vijaya and the Chola king, Rajendracola Deva I, whose kingdom was on the Coromandel coast of India. He conquered the key cities of the Sumatran empire on one of his expeditions; Sri Vijaya survived the attacks, but its power diminished gradually after this period. It was at this time still a prominent centre of learning; the reformer of Tibetan Buddhism, Atisha, studied in Sumatra c. A.D. 1020 under the priest Dharmakirti, who was considered the greatest scholar of his time. The name of the Shailendra dynasty, which had ruled Sri Vijaya since the 8th century, disappeared in the early 12th century. Resistance in Ceylon and the expansion of the Siamese toward the Isthmus of Kra put severe pressures on Sri Vijaya's resources. Malayu (Djambi), independent from about 1150, was conquered in 1275 by the Javanese king Kritanagara and made into a vassal state under a Javanese-educated Sumatran prince, thus placing the Palembang kingdom under close threat.

Soon after this date, Sri Vijaya became a vassal state and then, in 1377, a province of Java's Hindu Majapahit Empire, and was directly ruled by a Javanese governor. The ruling prince of Majapahit's vassal state Malayu, Adityavarman, on the other hand, gained greater autonomy by moving his residence to the highlands (c. 1350), among the Menangkabau. Hindu influence in the Padang Highlands dates back to the 8th century, but the rise of a strong Menangkabau kingdom seems related to the penetration of Hindu-Javanese influence in the 14th century. For a while Malayu had considerable power in Sumatra, but it did not challenge Java's hegemony.

**The Advent of Islam.**—In 1292 Marco Polo visited Sumatra. He mentioned Malayu, but not Sri Vijaya, among the kingdoms on this island. More important, he noted that the port town of Perlak (Keudepeurelak), in North Sumatra, was Islamic in religion. A few years later there was a Muslim state at the north tip called Samudra, which probably gave rise to the modern name of the island. The first great Muslim power was the city-state of Malacca across the straits. It had its beginnings as a Javanese-Sumatran trade centre in the twilight zone between the dominions of Majapahit and Siam, and sought protection from China when Siamese pressure became dangerous. In 1414 it had its first Muslim sultan, and from then on the attraction of Malacca's trade relations with the Middle East, India, and China drew ever more merchants in Sumatra and Java into the Muslim faith.

In the 16th century Atjeh arose as the main power in Sumatra. From the core area in the north tip, its sultans subdued in a series of holy wars the adjacent eastern and western coasts and even the Menangkabau, converting them to Islam. In the process Atjeh gained control over the pepper-growing districts of northern Sumatra. After the Portuguese had conquered Malacca (1511) the Achinese (Atjehnese) tried repeatedly to dislodge them, but without success. Atjeh, however, extended its influence over some other parts of the peninsula, especially Kedah and Perak which had valuable tin mines. From the tin and the pepper monopoly Atjeh grew rich. Under Iskandar Muda (1607–36) Atjeh might have become the great new sea power of the straits, had its fleet

not been defeated (1629) by the allied naval forces of Portugal, Malacca, Johore, and Pattani.

**The Dutch Period.**—The first Dutch ships to visit Sumatra arrived in 1599 on the roadstead of Atjeh, where they were attacked. Their leader Cornelius Houtman was killed, and his brother taken prisoner. Later, however, the Dutch East India Company (formed in 1602) was permitted to establish a factory there (1616) and the Achinese helped the Dutch in ousting the Portuguese from Malacca (1641). Then the Dutch turned on Atjeh, blockading its coasts and fomenting revolts among the peoples which Atjeh had subjected to its rule. By the Treaty of Painan (1662) the west coast principalities of Indrapura, Tikur, and Padang placed themselves under the protection of the company, which guaranteed their independence from Atjeh in exchange for the trade monopoly in these principalities, with pepper as a particularly rich prize. On the east coast the Dutch had already obtained a monopoly of the pepper trade by responding to requests from the sultans of Djambi (1615) and Palembang (1616) for military protection against threats from Atjeh and from Bantam of West Java respectively. The chieftains of Bangka and Billiton (Belitung) also sought the protection of the company, but the Dutch showed little interest in these islands until tin was discovered there in the 18th century. The English in the early 17th century had a factory at Atjeh and later one at Bengkulu (Benkoelen) on the southwestern coast. Bengkulu, founded in 1685, remained British until 1824.

Increasing British interest in East Asia, and thus in the Strait of Malacca, had been evident since the latter part of the 18th century. After the Napoleonic Wars England returned the East Indies to the Netherlands, but Sir Thomas Stamford Raffles, on his own initiative, purchased the island of Singapore (1819) from the sultan of Johore, although the latter had recognized the overlordship of Batavia over all islands of the Riuw Archipelago. This and other acts led to disputes with the Netherlands, which were settled in 1824 by the Treaty of London. The British gave up Bengkulu and their claims on Billiton, in return for Malacca and Dutch recognition of Singapore as a British possession. Furthermore, to remove the danger of the Dutch controlling the straits, the British obtained a promise from the Netherlands that it would respect the independence of Atjeh.

Until the latter half of the 19th century, the Netherlands colonial government exercised effective authority only in a few areas of Sumatra, and economic development was slow. In 1863, however, tobacco planting was started by private enterprise in Deli on the northeastern coast. This was the beginning of a remarkable transformation of this area from almost empty forest land to one of the most important estate areas in the Indies. The Padang Highlands were in tumult for decades because of a religious conflict (the Padri War), which ended only in 1845. Here exploitation of coal in the interior, and the building of railroads and of harbour works at Padang, stimulated economic progress in the last quarter of the 19th century. At the same time the Batak Highlands were opened up, and missions were established there. The only area that resisted Dutch control until the early 20th century was Atjeh.

In World War II Japanese troops seized Sumatra during February–March 1942. After the capitulation of Japan in 1945 the Dutch tried to reestablish their authority. A period of confusion followed. National independence movements blended in some regions with local revolutions, in which new leading groups eliminated the ruling aristocracies. Finally in 1949 the Netherlands transferred full sovereignty to the United States of Indonesia into which Sumatra was merged. In 1950 this federation was abolished and Sumatra became part of the Republik Indonesia, a centralized state with capital at Jakarta. Dissatisfaction with the policies of the central government in Jakarta, however, led in later years to several regional movements and insurrections in Sumatra. (See *Administration and Regionalist Movements*, below.) During 1964–65, in Indonesia's war of "confrontation" against Malaysia (q.v.), islands off Sumatra's east coast were used as bases for attempts to infiltrate saboteurs and guerrillas into the Malayan mainland. ## POPULATION

The population of Sumatra in 1961 was 15,739,363. The last detailed census was taken in 1930, establishing a population of 8,254,500, of whom 7,745,000 were Indonesians, 28,500 Europeans (mostly Dutch), 448,000 Chinese, and 33,000 other Asians. All Dutch citizens left the island in 1957, but there are groups of American and British people in estate and petroleum enterprises along the east coast. The Chinese are concentrated on the east coast and in the tin-producing islands of Bangka and Billiton. The highest density of population, about 400 per sq.mi. (155 per sq.km.), is in the estate district around Medan in North Sumatra. Densities between 200 and 400 per sq.mi. are characteristic of the Padang Highlands, the north coast of Atjeh, and the upland zone between Medan and Lake Toba, all being well-developed agricultural areas. At the other extreme are the malaria-ridden equatorial forests of Sumatra's broad eastern coastal plain (Jambi, Riouw, Siak), where the population averages less than 15 per sq.mi. (6 per sq.km.). The largest ethnic group is that of the Menangkabau, estimated (1961) at 3,500,000. The Batak number about 2,000,000, the Achinese 2,000,000; the remaining half of the population are Malays, Palembangs, Lampongs, and other related groups. Nine-tenths of the total population live in rural villages or small towns. The main cities are Palembang (1961 pop. 474,971), Medan (479,098), and Padang (143,699).

The relatively sparse population, compared to that of Java, is related to infertile old acidic soils covering much of the higher plain, and to the extensive marshes along the coast. More intensive use of land is possible, however, as shown by the Javanese colonization in south Sumatra. Dutch attempts to alleviate overpopulation in Java by resettling the Javanese in Sumatra date from 1905, but it was not until the 1930s that the movement gathered momentum. The main area of colonization was that of the Lampong. In the southern lowlands of the Lampong district the soil had been enriched by the volcanic ash cover from Krakatau. Farther northward the acidic soils of the upper plain proved good if irrigated with water transporting silt from the andesite highlands, such as the lands along the middle Sekampung River, north of Telukbetung. In 1940 there were 160,000 Javanese in this area and several thousands near Palembang and Bengkulu. After independence resettlement was resumed, providing homes for an estimated additional 300,000 Javanese in south Sumatra.

## ADMINISTRATION AND REGIONALIST MOVEMENTS

Under the Dutch regime Sumatra, with adjacent islands, was divided into ten residencies. After independence, the residencies were eliminated and replaced by three provinces of North, Central, and South Sumatra. Later six provinces were created, each with a presidentially appointed governor and an appointed regional legislative council of representatives. The provinces with their capitals are: Atjeh (Kutaradja); Sumatera Utara or North Sumatra (Medan); Djambi (Jambi); Riouw (Pakanbaru); Sumatera Barat or West Sumatra (Bukittinggi); and Sumatera Selatan or South Sumatra (Palembang).

The increase in the number of provinces was brought about by the realization that the old units were too large to accommodate the regional diversity. Atjeh (q.v.) in North Sumatra was in armed revolt from 1953 to 1957; at least one of the aims of its leaders was autonomy, which was granted in 1956. Regional movements and open insurrections also occurred in other parts of Sumatra. Their purpose, as announced, was not secession from the Republic of Indonesia, but concern for local welfare which, according to the regional leaders, had been neglected by the central government in Jakarta. Among the orthodox Muslims of Sumatra there also was suspicion of leftist leanings in the central government. In December 1956 the regional military commanders, taking over the civil administration, set up revolutionary committees (Banteng ["wild buffalo"] councils) in Medan and Padang, and proceeded to obtain funds by diverting trade revenues from Jakarta to local treasuries. The Banteng Council of Central Sumatra in early 1957 acceded on its own initiative to the claims of Jambi and Riouw for separate status (this was later legalized by the central government). In February 1958 the regionalists

formed a Revolutionary Government of the Republic of Indonesia which included several former cabinet ministers and prominent military leaders. In March-May 1958 the rebels were attacked and defeated by the Indonesian armed forces. The roots of dissatisfaction, however, persist. Sumatra, earning most of the foreign exchange of Indonesia, desires a greater return in the form of schools, roads, and other public works. Within the island the diverse social groups demand reorganization. (See also INDONESIA, REPUBLIC OF: *Administration and Social Conditions*.)

## THE ECONOMY

Sumatra, not having the excessive population of Java, and possessing rich natural resources, contributes well over half of the exports of raw materials from Indonesia.

**Agriculture.**—The soils derived from young basic and neutral volcanic ejecta are very fertile. They occur in the Batak Highlands and coastal areas of north Atjeh and the adjacent zone around Medan, along the central west coast and in the Padang Highlands and farther south in the Palembang Highlands and the Lampong district. In these areas cultivation gives good yields. In other areas the soils are derived from deeply leached parent material, or, if volcanic in origin, from acidic ejecta, which are, on the whole, of low fertility. For these reasons much of the broad east coast plain is of limited value for most crops. Agriculture in Sumatra is of two types: indigenous as practised by smallholders, and European on large estates.

**Smallholder Agriculture.**—The smallholder (small owner) is first and foremost a producer of foodstuffs for domestic consumption, and only secondarily of export commodities. Rice is the predominant crop, raised on permanent fields by flooding or irrigation (*sawah*) or on temporary clearings in the forest (*ladang*). Large quantities of rice have to be imported to feed the labour force on the estates and the urban population. In the hope of increasing rice yields the Indonesian government established pools of equipment from which smallholders could borrow tractors and other kinds of machinery. Other crops exclusively grown for home consumption are maize (corn), root crops, and vegetables. The surplus farm commodities, such as coffee, copra, tobacco, betel nut, kapok, and peanuts, are exported. The government encourages the production of ramie fibre, which has to some extent superseded that of sisal. Two important export crops are pepper and rubber, the former a traditional cash crop, now overshadowed by rubber which was quickly adopted by the Indonesians after introduction on estates in the early 20th century. The hevea tree, not needing rich soil, has proved a special boon to the people of the eastern plain, though rubber is grown in all lowland areas and Sumatra produces about two-thirds of Indonesia's smallholder rubber. But in the mid-1960s yields were decreasing because most hevea trees were old and little replanting had been done since 1940. The farmers in Sumatra are better off than their counterparts in Java: their holdings are larger, affording the space for cash crops, which the Javanese often lack. In Sumatra the Chinese middleman has a minor role, thus leaving much of the local trade in Indonesian hands. Income per capita in Sumatra is probably more than double that of Java.

**Estates.**—European estates, or plantations, were established on Sumatra in the latter part of the 19th century. As labour was scarce, estates either specialized on a commodity that required relatively little care, such as rubber, or they imported labour from China, later from Java, for the intensive cultivation of tobacco and tea. Estates are found in almost all parts of the island, but the great concentration is in the so-called east coast, actually a zone centring on Medan, from about Aru Bay in the northwest to the Barumun River in the southeast, composing the former principalities of Langkat, Deli, and Asahan in the plain and Serdang, Langgun and Karo lands in the hills north of Lake Toba. Cultivation of high-grade wrapper tobacco started in the 1860s. Thirty years later, coffee estates were added. Then, in the early 20th century hevea rubber was introduced, and in the next decade the sisal was established.

The number of estates greatly declined during and after World

War II. Under the Japanese occupation large areas of estate lands were turned over to the idle workers for food production. Deterrents to production in postwar rehabilitation were the disturbed political conditions, changed labour relations, and stringent foreign exchange controls. Most estates were Dutch-owned and in late 1957 these were seized by the Indonesian government, in retaliation for Dutch unwillingness to hand over West New Guinea (Irian Barat), and placed under Army control. The Basic Agrarian Act of 1960 placed restrictions on all remaining foreign estates.

**Forest Products.**—Over 60% of Sumatra is forest-covered. The local population obtains construction materials, firewood, and charcoal from them. There is good timber, such as various species of dipterocarps, but exploitation is hampered because the forests are mixed. Commercial production on a small scale is mainly in accessible areas along the rivers in the eastern lowland. Somewhat larger enterprises, including sawmills, are along the coast and in the Riouw Islands, where the Chinese have concessions. From there logs, firewood, and charcoal are normally exported to Singapore. The timber cut in Sumatra is about 1,000,000 cu.m. (rough timber equivalent), one-third of Indonesia's total output. The forests also yield gums and resins, such as jelutong (used in chewing gum), gutta-percha, damar, and copal.

**Fisheries.**—As fish is the common animal protein accompanying the rice diet, fishing is widespread in the rivers and coastal waters. Intensive fish-raising in ponds, as on Java, is rare. The largest catch comes from the Strait of Malacca and the waters surrounding the Riouw Archipelago. The great fishing port of Sumatra is Bagan-Siapiapi, at the mouth of the Rokan, which handles an annual catch of about 80,000 metric tons, almost two-thirds of the sea fisheries' yield of Sumatra. There a large part of the catch is cured, smoked, or dried, and forwarded to Java. Besides fish, trepang (sea slugs), prawns (from which the delicacy *krupuk* is made), and other shellfish are caught. Other fishing centres are near Telukbetung, at Bengkulu, and on Bangka Island.

**Minerals.**—Sumatra with its adjacent islands is rich in minerals, among which petroleum, tin, bauxite, and coal are foremost, and gold, silver, tungsten, iron, clay, and limestone are of minor importance.

Petroleum is recovered from long, narrow anticlines in the Late Tertiary sediments east of the mountains, from Palembang to Atjeh. Sumatra is the richest producer of crude oil in Indonesia, with about 70% of the total production (over 160,000,000 bbl. in the early 1960s). Palembang, in South Sumatra, is the main refining centre; there are refineries in Sungaierong and in Pladju, both connected by pipelines to the oilfields west and southwest of the city. A field in the Lirik region, central Sumatra, is also exploited. There are wells north and northwest of Pekanbaru between the Siak and Rokan rivers. Until 1959 all crude oil was piped to the Siak River and then into river tankers which carried it 93 mi. (150 km.) to the terminal at the seaport of Pakning. Since then 30-inch pipelines connect the fields (Minas, Pungut, and Duri) with a new ocean harbour at Dumai on Rupa Strait, equipped to receive oil tankers up to 84,000 tons capacity, as well as oceangoing cargo ships.

Tin occurs in the Riouw Archipelago and on the islands of Bangka and Billiton, but only the latter two and Singkep in the Riouw group are significant producers. Ore lodes occur, but most of the tin is extracted from the alluvium in the valleys and their continuation in the drowned continental shelf. Tin mining started in Bangka in the 18th century and in Billiton in 1852. The mines are operated by the government. The rich deposits of tin in these islands have made Indonesia the second largest tin-producing country. As the smelters existing before the war have not been rehabilitated, the concentrates are shipped abroad.

Bauxite was discovered shortly before World War II in the Riouw Archipelago, where it covers large areas to a shallow depth and in varying concentration. The ore, a weathering product of granite and diorite, is dug in open-pit mines on Bintan and the adjoining small islands. Bauxite is shipped abroad for processing, mainly to Japan.

The coal deposits on Sumatra are of Tertiary age. The Umbilin field in central Sumatra near Sawahlunto (in the Padang High-

lands) is of Eocene age and covers about 40 sq.mi. (104 sq.km.). In south Sumatra some Miocene lignite beds have been transformed into excellent coal by intruding andesite plugs. Here lies the Bukit Asem mine, south of the Muaraenim. Both are government owned and operated and produce more than three-quarters of the total output of coal in Indonesia. Production is far less than in prewar years, causing a shortage for the railroads, which are the main consumers. The coal is not suitable for coking. Gold and silver occur in the Redjang-Lebong highlands and in some other sections of the island, but production is negligible.

**Transport and Communications.**—The estate area on the east coast, the Padang Highlands, and south Sumatra have fairly good land transportation networks but the remainder of the island depends on mountain trails and rivers. The main road from Medan to the west coast runs past Pematangsiantar to the resort town of Prapat on Lake Toba and descends to the small port of Sibolga on the west coast; from there it runs through mountain valleys and connecting pass routes to Bukittinggi (formerly Fort de Kock) and Padang (qq.v.). The plain of central Sumatra has few roads apart from those built by the petroleum companies. In the south most of the large towns are linked by main roads.

The railways are divided into three sections. In north Sumatra a narrow-gauge line runs northwest from Medan to Kutaradja, the capital of Atjeh, and to its port Uleelheue, serving rubber plantations and pepper gardens. Southward from Medan the line runs through the tobacco, rubber, and oil palm estates, to Rantauparapat, with a branch line from Tebingtinggi to Pematangsiantar, through tea plantations in the foothills north of Lake Toba. Belawan, connected by a 12-mi. (19 km.) railway to Medan, is the chief ocean port of the estate district; Tandjungbalai, on the Asahan River, also serves as a shipping point. In central Sumatra steep-gradient railways with many tunnels connect the port of Padang on the west coast with the Umbilin mine in the highlands to the east and with Bukittinggi and Pajakumbuh toward the north, where coffee is grown. In south Sumatra Pandjang on Lampung Bay (export of rubber and pepper) and the commercial centre of Telukbetung are connected by rail with Palembang on the Musi River, the shipping point for petroleum products, rubber, coffee, and forest products. Palembang is also connected with the hinterland by a branch line from Perabumulih, which runs southwestward past Muaraenim (with a spur to the Bukit Asem coal mines) and Tebingtinggi, to Lubuklinggau. Each river has its port, several of them well inland. The tin islands have several ports: Pangkalbalam, Belinju, and Muntok on Bangka, which ship pepper in addition to tin; and Tandjungpandan on Billiton. The main trade centre on Bintan is Tandjungpinang. The larger cities of Sumatra are served by the Garuda Indonesian Airways.

**SUMBA** (also known as SANDALWOOD), one of the Lesser Sunda Islands in East Nusa Tenggara Province, Indonesia, lies west of Timor and south of Flores, from which it is separated by the Sumba Strait. Area 4,306 sq.mi. (11,153 sq.km.). It is dominated by heights of 2,200–4,000 ft. (670–1,220 m.); unlike the islands to the north, Sumba has no volcanoes. Several bays on the north coast give good anchorage, the best being that of Waingapu, the chief town (pop. [1960 est.] 5,000). The rivers, most of which are unnavigable, are important for agriculture. The average annual rainfall is 63.7 in. (1,618 mm.), resulting in only light forest and much grassland. Most of the sandalwood is gone. On the island's grazing grounds are bred some of the finest horses in the country—the Sandalwood breed—and fine cattle (Ongole), both of which formerly figured largely as exports. Maize is the main

crop; in addition, rice, coffee, tobacco, coconuts, vegetables, and fruit are grown in a primitive manner, copra being exported. The woven cloth of Sumba, adorned with animal patterns, is famous for its artistic quality.

The population (1961) was 251,126, consisting, apart from the indigenous Sumbanese, of people from Flores, Sawu, and Roti islands; they are mostly animist, though some are Muslim. Traditional customs include marriage by dowry, and polygamy is fairly common among the upper classes. There is no written form of the Sumbanese language, which is allied to that of Sawu. Sumba has numerous megalithic monuments.

The sandalwood of Sumba attracted attention to the island in the 17th century, when Sumba appears to have been a tributary of the state of Bima, in Sumbawa. Later Sumba became independent of Sumbawa, and treaties were concluded in 1756 with the Dutch. Between 1856 and 1874 new treaties were made, but there were frequent difficulties with the inhabitants because of piracy and slave raids. In 1901 and 1914 the Dutch landed troops on the island. (E. E. L.; J. O. M. B.)

**SUMBAWA**, one of the Lesser Sunda Islands in East Nusa Tenggara Province, Indonesia, lies between Lombok and Flores islands, separated from the former by Alas Strait and from the latter by Sape Strait and Komodo Island. In 1960 the population was estimated at well over 400,000. Sumbawa is 175 mi. (282 km.) long by 55 mi. (89 km.) at its widest, but deep coastal indentations divide the island into several peninsulas. The largest bay is that of Saleh on the central north coast with Mojo Island at its mouth. More to the east is the narrow and deep Bima Bay, an excellent natural harbour. The island is very mountainous, with rocky coasts and only a few small plains. Some of the mountains are volcanic, the highest being Mt. Tambora (9,350 ft. [2,850 m.]), whose tremendous eruption in 1815 caused the death of about 50,000 inhabitants and the emigration of about 35,000 to other islands. The average annual rainfall is 90 in. (2,286 mm.) in the central mountains and 50 in. (1,270 mm.) along the north coast; little rain falls in the east monsoon, from June to September. Dense forest occurs only on the mountains of the central watershed. The sappan (red dye) wood, formerly exported to China, has largely been depleted. Because of shifting cultivation, followed by grazing, large areas are now covered by thorn brush.

The people of the western part of the island are of Malay stock, but in the eastern interior Papuan (Oceanic Negroid) traits are quite strong. Islam is the prevailing religion.

Agriculture consists of wet rice cultivation on a small scale on permanent fields along the north coast, but most crops (maize, beans, tubers) are raised on temporary fields. Some coffee is grown in the highlands; coconut palms in the coastal zone yield copra for export. Raising of cattle, goats, and horses is an important feature of the economy, partly for export. A fair-weather motor road traverses the northern part of the island, from Sumbawa-Besar (with an airfield) to Bima. These two towns and Taliwang (on the west coast) are ports of call for ships of the interisland service.

Sumbawa was once a part of the Javanese Majapahit kingdom (see JAVA: History). Later it came under the suzerainty of the sultanates of South Celebes. The defeat of the sultan of Gowa (1668) brought Sumbawa under Dutch authority. From 1701 onward a Dutch representative resided at Bima, but the island was not brought under effective control until 1905. Sumbawa was occupied by Japanese troops during World War II and became part of the Republic of Indonesia in 1949. (J. O. M. B.)

**SUMERIAN LANGUAGE.** Sumerian is the oldest written language in existence. First attested about 3100 B.C. in southern Mesopotamia, it flourished during the 3rd millennium B.C. It was replaced about 2000 B.C. as a spoken language by the Semitic Akkadian (Assyro-Babylonian), but it continued in written usage almost to the end of the life of the Akkadian language (q.v.), around the beginning of the Christian era. Sumerian never extended much beyond its original boundaries in southern Mesopotamia: the small number of its native speakers was entirely out of proportion to the tremendous importance and influence Sumerian exercised on the development of the Mesopotamian and other

ancient civilizations in all their stages.

**History.**—Four periods of Sumerian can be distinguished: Archaic Sumerian, Old or Classical Sumerian, New Sumerian, and Post-Sumerian.

Archaic Sumerian embraced a period from about 3100 B.C. when the first Sumerian records make their appearance, down to about 2500 B.C. The earliest Sumerian writing is almost exclusively represented by texts of business and administrative character. There are also school texts in the form of simple exercises in writing signs and words. The Archaic Sumerian language is still very poorly understood, partly because of the difficulties surrounding the reading and interpretation of early Sumerian writing and partly because of the meagreness of sources.

The Old or Classical period of Sumerian lasted from about 2500 to 2300 B.C. This period is represented mainly by records of the early rulers of Lagash. The use of the Sumerian language is attested not only in business, legal, and administrative texts but also in royal and private inscriptions, mostly of votive character, letters, both private and official, and incantations. These sources are much more numerous than those of the preceding period, and the writing is explicit enough to make possible an adequate reconstruction of Sumerian grammar and lexicon.

During the period of the Sargonic dynasty, the Semitic Akkadians took over the political hegemony of Babylonia, marking a definite setback in the progress of the Sumerian language. During this period, the Akkadian language was used extensively throughout the whole area of the Old Akkadian empire, while the use of Sumerian was gradually limited to a small area in Sumar proper. Toward the end of the dynasty the Sumerian elements came again to the fore, marking in turn a setback to the progress of Akkadian. The New Sumerian period came to an end about 2000 B.C., when new inroads of the Semitic peoples from the desert succeeded in destroying the supremacy of the 3rd dynasty of Ur and in establishing the Semitic dynasties of Isin, Larsa, and Babylon. The New Sumerian period is characterized by an extraordinary number of administrative texts.

The period of the dynasties of Isin, Larsa, and Babylon is called the Old Babylonian period, after Babylon, which became the capital and the most important city in the country. During this period the Sumerians lost their political identity, and the Sumerian language gradually disappeared from spoken use. However, it continued in written usage to the very end of the use of cuneiform writing. This is the last stage of the Sumerian language, called "Post-Sumerian."

In the early stages of the post-Sumerian period the use of written Sumerian is extensively attested in legal and administrative texts, as well as in the royal inscriptions. The latter are often bilingual, that is, in Sumerian and Babylonian. Many Sumerian literary compositions, which came down from the older Sumerian periods by way of oral tradition, were put down in writing for the first time in the Old Babylonian period. Many more were copied by industrious scribes from originals now lost. The rich Sumerian literature is represented by texts of varied nature, such as myths and epics, hymns and lamentations, rituals and incantations, and proverbs and the so-called "wisdom" compositions. For many centuries after the Old Babylonian period, the study of Sumerian continued in the Babylonian schools. As late as the 7th century B.C., Ashurbanipal, one of the last rulers of Assyria, boasted of being able to read the difficult Sumerian language, and from an even later period, in Hellenistic times, there are some cuneiform tablets which show Sumerian words transcribed with the letters of Greek writing.

**Rediscovery.**—At the time of Christ, all knowledge of Sumerian disappeared along with cuneiform writing, and in the succeeding centuries even the name Sumer vanished from memory.

Unlike Assyria, Babylonia, and Egypt, whose histories and traditions are amply documented in biblical and classical sources, there was nothing to be found in non-Mesopotamian sources anywhere to make one even suspect the existence of the Sumerians in antiquity, let alone to appreciate fully their important role in the history of early civilizations.

When the decipherment of cuneiform writing was achieved in

the early decades of the 19th century, three languages written in cuneiform were discovered: Semitic Babylonian, Indo-European Persian, and Elamite, of unknown linguistic affiliation. Only after the texts written in Babylonian had become better understood did scholars become aware of the existence of texts written in a language different from Babylonian. When the new language was discovered it was variously designated as Scythian or even Akkadian, that is, by the very name now given to the Semitic language spoken in Babylonia and Assyria. As knowledge of the new language grew, it was given the correct name of Sumerian.

**Characteristics.**—The linguistic affinity of Sumerian has not yet been successfully established. Ural-Altaic (which includes Turkish), Dravidian, Brahui, Bantu, and many other families of languages have been compared with Sumerian, but no theory has gained common acceptance. Sumerian is clearly an agglutinative language in that it preserves the root intact while expressing the various morphemic changes, through the concatenation principle, by means of prefixed, infixed, and suffixed elements. The difference between nouns and verbs, as it exists, e.g., in the Indo-European or Semitic languages, is unknown to Sumerian. The word *dug* alone means both "speech" and "to speak" in Sumerian, the difference between the noun and the verb being indicated by syntax and different affixes.

The phonemic system of Sumerian consisted of four vowels *a, i, e, u*, and fifteen consonants *b, d, g, h, k, l, m, n, p, r, s, š, t, z*. In the noun gender was not expressed. Plural number was indicated either by the suffixes *-me* (or *-me + esk*), *-hia*, and *-ene* or by reduplication, as in *kur + kur*, "mountains." The relational morphemes of the noun, corresponding approximately to the cases of the Latin declension, are: *-e* for the subject (nominative), *-a(k)* "of" (genitive), *-ra* "to," "for" (dative), *-a* "in," *-ta* "from" (ablative), *-da* "with" (committive), and *-sh(e)* "for (a period of time)," "for (the purpose of)," etc.

The Sumerian verb, with its concatenation of various prefixes, infixes, and suffixes, presents a very complicated picture. The elements connected with the verb follow a rigid order: modal elements, tempo elements, relational elements, causative elements, object elements, verbal root, subject elements, and intransitive present-future elements. In the preterit transitive active the order of object and subject elements is reversed. The verb can distinguish, in addition to person and number, transitive and intransitive, active and passive, and two tenses, present-future and preterit.

Several Sumerian dialects are known. Of these the most important are *eme-KU*, the official dialect of Sumerian, and *eme-SAL*, the dialect used often in the composition of hymns and incantations.

Kramer, *The Sumerians* (1963).

**SUMMARY JURISDICTION**, in Anglo-American law, ordinarily designates the jurisdiction of a magistrate or judge to conduct proceedings resulting in a conviction or order without trial by jury. Since in the later common law the only recognized mode of trial, except in cases of contempt, was jury trial, summary jurisdiction is almost entirely a creature of statute. In the United States, despite federal and state constitutional provisions guaranteeing trial by jury, it is generally held that certain petty offenses may be tried summarily. The trial of such cases is usually more informal and expeditious than those for more serious offenses. Civil suits in which the amounts involved are small may also be tried without right of jury trial. In England crimes are classified as either summary offenses, which are tried by magistrates' courts, and indictable offenses, to which the right of jury trial attaches. There is also a class of offenses that are both summary and indictable. Under the terms of the Magistrates' Courts Act, 1952, most petty offenses punishable by imprisonment for more

than three months may, however, be tried on indictment. Provision is also made for the summary trial of some common indictable offenses when certain conditions are satisfied. The English law includes some civil proceedings within the summary jurisdiction of the magistrates. See also COURT. (F. A. A.)

**SUMMER SCHOOL.** Universities and colleges in the United States offered instruction during the summer months after the 1870s, and more especially after about 1905. The earliest programs of summer study retained many of the qualities of the customary summer vacation. In 1869 N. S. Shaler of Harvard university arranged a field trip in the mountains of Colorado for students of geology. Louis Agassiz of Harvard offered field work in a zoological laboratory established on Penikese Island in Buzzards bay, Mass., in 1873. In 1888 C. O. Whitman founded the Marine Biological laboratory at Woods Hole, Mass., as a centre for researchers in biology.

An early form of summer study which greatly influenced the growth of schools was the Chautauqua summer assembly (see LYCEUMS AND CHAUTAUQUAS) which began with a ten-day session in 1874, enlisting the co-operation of many notable scholars and educators. One of these, William Rainey Harper, who conducted courses in Hebrew and in Old Testament literature, became president of The University of Chicago in 1891. Moved by the success of his Chautauqua experience he provided for a university calendar of four quarters, of which the summer one was an integral part of the university year. Shortly thereafter other universities provided for summer sessions, many of them offering courses which could be counted toward the baccalaureate degree.

One of the factors contributing to the growth of summer schools was the demand for trained teachers in a rapidly expanding system of public schools. During the first quarter of the 19th century teachers depended for help upon the county "normals," one-day conventions which were held at many points throughout the country. By 1850 more elaborate institutes, often of two weeks duration, were common, and were provided for by law in several states.

The first six-week summer course in education for public-school teachers was offered at Martha's Vineyard, Mass., in 1878. This school emphasized teaching methods and in 1890 enrolled 700 students in its elementary, high school and academic departments. Because of the seasonal nature of public-school teaching and the rapid increase in numbers of public-school teachers, U.S. summer schools until the middle 1920s offered chiefly undergraduate courses in educational methods. After the 1920s, standards of qualification for public-school teachers reached so high a level that the emphasis of this aspect of summer schools, especially at the large universities, shifted toward postbaccalaureate courses.

A later development in summer schools was the introduction of highly specialized conferences, workshops and seminars for selected groups of professional and industrial people. Courses of this sort make the results of research at educational institutions available to industrial technicians, teachers and other professional persons.

Summer sessions of varying lengths are often provided within a single institution. At universities employing a calendar of four quarters, many courses offered in the summer quarter are so organized that students may enroll and receive credit for either the first or the last five or six weeks of the quarter. Other institutions schedule sessions of different lengths. Summer sessions in high schools became fairly common after World War I as a means of offering acceleration to superior students, making up failures in the regular school year and for general enrichment.

(H. W. Ss.)

#### GREAT BRITAIN AND EUROPE

The summer school idea developed in Great Britain and Europe especially after the end of World War II for three main reasons: (1) evening classes alone were not sufficient to serve the educational needs of workers; (2) university and school teachers found that the extension of their work beyond the lecture and classroom was of immense value and that the long summer holidays were clearly a time when the most ambitious experiments could be car-

ried out; (3) group recreational activities (particularly for young people brought up in industrial centres) carried out by the principal youth movements, such as the Boy Scouts and Girl Guides, showed the value of recreational education of this kind.

The work of the folk high schools, started in Denmark by Bishop N. F. Grundtvig (q.v.) and his followers in the middle of the 19th century, provided one of the chief inspirations for the early experiments in summer schools. Great impetus to the movement came, naturally, with the introduction of paid holidays; and in Britain many new organizations sprang up to continue the work begun by the Workers' Educational association. Government departments, local authorities, professional associations, trades unions, learned societies and most voluntary youth organizations followed the lead. The movement spread in many countries and became international at an early stage. Universities took the lead in making their premises available for students from abroad and summer courses beginning with language study rapidly developed in European university towns.

After World War II the rate of growth became extremely rapid, and international summer schools were one of the first preoccupations of UNESCO during its early years, as they continued to be.

In the second half of the 20th century there were few holiday resorts or university towns in Europe where buildings were not taken over during the summer months. Many were organized for a limited number of persons who were invited to take part and these were usually not advertised. Some general idea of the numbers of schools may be obtained from three sources: (1) in Great Britain the National Institute for Adult Education publishes each year a list of residential short courses, held between April and September in the United Kingdom, their list for one year containing details of well over 600 courses; (2) in Great Britain again, the Central Bureau for Educational Visits and Exchanges published a list which mentioned over 200 courses in Europe open to students from the United Kingdom, these courses being held in Austria, Belgium, Bulgaria, Denmark, the Republic of Ireland, Finland, France, the German Federal Republic, Greece, the Netherlands, Italy, Norway, Portugal, Spain, Sweden, Switzerland, the U.S.S.R. and Yugoslavia; (3) the UNESCO annual supplement to *Study Abroad*, which includes details of many hundreds more throughout the world. (See also STUDENT AM.)

These figures apply only to courses open to all and devoted to a formal course of study. Summer schools where children of secondary and even of primary school age are taken to camps, schools and other centres for a wide range of educational activities are even more numerous.

The term "summer school," formerly applied only to adult and university studies and to refresher courses for teachers and other professional persons, has grown in meaning to include the extension of all branches of education into the summer holiday period. One great value of the summer school lies in the bringing together of students in pleasant surroundings where they may intensify the study of particular subjects (especially geography, geology, botany and archaeology at field centres).

**SUMMIT**, a city and suburban residential community of New Jersey, U.S., in Union County, on an escarpment of Watchung Mountain adjacent to Springfield, Millburn, and Chatham, is 10 mi. (16 km.) SW of Newark and 19 mi. (31 km.) W of New York City. Founded as Turkey Hill in 1710, it was renamed Summit in 1837 and incorporated as a city in 1899. The site of a lookout post and signal tower for General Washington's troops alerting them to any movement of the British in the Revolutionary War is commemorated by a marker showing the location of the alarm gun "Old Sow." Summit's chief industries are chemicals, pharmaceuticals, textiles, and floristry.

For comparative population figures see table in NEW JERSEY: Population. (D. N. A.; M. P. M.)

**SUMNER, CHARLES** (1811–1874), U.S. statesman, a leader of the anti-slavery forces before and during the Civil War, was born in Boston, Mass., on Jan. 6, 1811. He graduated in 1830 from Harvard College and in 1834 from Harvard Law School. He

THE GRANGER COLLECTION

CHARLES SUMNER. PHOTOGRAPHED BY MATHEW BRADY

interrupted his law practice when he was 26 for a three-year sojourn in Europe (1837–40) which resulted in friendships with many influential Europeans. Upon his return he devoted much time to lecturing at Harvard and to editing legal works. He crusaded for many reforms, including prison reform, world peace and Horace Mann's plans for educational improvement. His especial dedication to "absolute human equality, secured, assured, and invulnerable," made him an effective champion of the abolition of slavery.

In 1851 Massachusetts Free Soilers and Democrats nominated Sumner for the U.S. Senate, and after a heated contest in the legislature he was elected. As a U.S. senator he was in an arena well suited to his talents and soon became famous. On Aug. 26, 1852, he delivered the first of many philippics: "Freedom national Slavery sectional." In this slashing tirade he flayed the Compromise of 1850 and those who supported it, gave hope to abolitionists, and alarmed all compromisers. On May 19–20, 1856, he denounced the "Crime against Kansas" (the Kansas-Nebraska Act, as "in every respect a swindle" and characterized its authors, Senators Andrew P. Butler and Stephen A. Douglas, as myrmidons of slavery. Two days later Congressman Preston S. Brooks of South Carolina invaded the Senate, labeled the speech a libel on his state and on his uncle, Senator Butler, and then severely beat Sumner with a cane. It took three years for him to recover from the beating. He was meanwhile reelected to the Senate where his empty seat was regarded as an effective symbol of freedom of speech and the abolition movement.

His prominent role in organizing the Republican Party and his Senate seniority earned for Sumner the chairmanship of the Senate Foreign Relations Committee on March 8, 1861. Close acquaintance with Cobden, Bright, Gladstone, and the duke and duchess of Argyll, and with many other influential Europeans, gave weight to his views abroad. Sumner used his knowledge of European views to persuade President Lincoln to give up Confederate commissioners James M. Mason and John Slidell after their capture aboard the "Trent" in November 1861. This mediation helped to preserve peace between Britain and the United States.

Following the Civil War, Sumner became an implacable foe of Pres. Andrew Johnson and Johnson's plan for reconstruction of the South. As a prerequisite for readmission to the Union, he believed that the Confederate states should provide constitutional guarantees of equal voting rights to Negroes, and he secured congressional approval of this scheme.

In 1870 Sumner led the opposition that defeated Pres. Ulysses S. Grant's plan to annex Santo Domingo. As a result, Grant apparently brought about Sumner's removal (March 10, 1871) from the chairmanship of the Foreign Relations Committee. The bout almost broke Sumner, but he nevertheless used his influence to win approval by the Senate in 1871 of the Treaty of Washington which helped improve and stabilize relations between the U.S. and Great Britain.

Sumner's last years were saddened by varying misfortunes. His marriage in October 1866 ended in divorce within a year. His greatest act of magnanimity in the Senate was doomed to misunderstanding. In 1872 he introduced a resolution providing that the names of battles with fellow citizens should not be placed on the regimental colours of the U.S. Army. The Massachusetts legislature censured this resolution as "an insult to the loyal soldiery of the nation" and asserted it met "the unqualified condemnation of the people of the Commonwealth." But early in 1874 the legislature rescinded its action. On March 10, 1874, acting against his doctor's orders, Sumner went to the Senate to hear his colleague

report that the censure had been rescinded and that he had been absolved. Stricken that night with an attack of angina pectoris, Sumner died the next day.

Wrong in some things, careless with personal invective, stubborn and uncompromising, Sumner nonetheless ranked as one of America's best crisis leaders. He stood always for principle and honesty, and perhaps that explains his estrangement from the postwar age.

Beale, *The Critical Year* (1930); David Donald, *Charles Sumner and the Coming of the Civil War* (1960). (F. E. V.)

**SUMNER, JAMES BATCHELLER** (1887–1955). U.S. biochemist who discovered that enzymes can be crystallized, was awarded the 1946 Nobel prize in chemistry with W. M. Stanley and J. H. Northrop. Born Nov. 19, 1887, in Canton, Mass., Sumner received his bachelor's degree in 1910 and his doctor's degree in 1914 from Harvard university. He taught at Mt. Allison college, Sackville, N.B., and at Worcester Polytechnic institute. In 1914 he became assistant professor and in 1929 professor of chemistry at the medical college of Cornell university, Ithaca, N.Y., where he remained until his retirement in July 1955. He had studied in Brussels, Stockholm and Uppsala. He was a member of the commission for relief in the Belgian Educational foundation 1921–22. He was awarded the Scheele medal at Stockholm in 1937. In 1947 he became the director of the Cornell laboratory of enzyme chemistry, established by the trustees of the university in recognition of his investigations.

Sumner's early work included the study of urea formation and the estimation of sugar in urine. In 1926, after chemists had hoped to isolate an enzyme, Sumner observed urease, an enzyme essential to the nitrogen cycle. The first enzyme to be prepared in a laboratory, it was a remarkable contribution. In 1937 Sumner crystallized the important enzyme catalase, which influences reactions involving hydrogen peroxide and protects the living cells from this compound, which they produce during their respiratory process. Sumner contributed to the purification of coenzyme I, lipoxidase and saccharase. He published *Biological Chemistry* in 1927. With G. F. Somers he wrote three editions of the two books *Chemistry and Methods of Enzymes* and *Laboratory Experiments in Biological Chemistry*, and with Karl Myrback compiled four books on *The Enzymes: Chemistry and Mechanism of Action* (1950–52). He died Aug. 12, 1955.

See E. Farber, *Nobel Prize Winners in Chemistry, 1901–1961* (1963). (V. Bw.)

**SUMNER, WILLIAM GRAHAM** (1840–1910). U.S. social scientist, an influential teacher and prolific publicist, was born in Paterson, N.J., on Oct. 30, 1840. He studied at Yale (A.B., 1863); and at Geneva, Göttingen and Oxford (1863–66); tutored at Yale (1866–69); served as a priest in the Episcopal Church (1869–72); and was professor of political and social science at Yale (1872–1909). He was president of the American Sociological society in 1909. He died in Englewood, N.J., April 12, 1910.

Like Herbert Spencer, Sumner expounded in many essays on current issues his firm belief in *laissez faire*, individual liberty and the innate inequalities among men. As a social Darwinist he viewed competition for property and social status as resulting in a beneficent elimination of the ill-adapted and the preservation of racial soundness and cultural vigour. For him the middle class Protestant ethic of hard work, thrift and sobriety exemplified those virtues conducive to wholesome family life and sound public morality. Foreseeing the drift toward the welfare state, but viewing poverty as the natural result of inherent inferiorities, he opposed all proposals that smacked of paternalism because they imposed unequal burdens on that class, his "forgotten men."

In his famous *Folkways* (1906), he found the origin of customs and morals in instinctive responses to the stimuli of hunger, sex, vanity and fear, selectively guided by pain and pleasure. He emphasized their inherent irrationality and resistance to reform. His notes became the basis of *The Science of Society*, 4 vol. (1927–28), edited by A. G. Keller.

See **ETHICS, HISTORY OF**; *Ethical Relativity*. (F. H. Hs.)

**SUMPTUARY LAWS**, a term originally used to denote regulations designed to restrict extravagance in food, drink, dress, household equipment and the like, usually on religious or moral grounds. More recently, the term has been applied to laws which either directly prohibit the manufacture or consumption of certain commodities or which influence their consumption indirectly through excise taxes. In the case of this more recent usage, the regulations are ordinarily defended on religious or moral grounds or on the grounds of public welfare.

Sumptuary laws have an ancient origin; numerous instances are to be found in ancient Greece. All the inhabitants of Laconia, for example, were forbidden to attend drinking entertainments and the Lacedaemonians were forbidden to possess a house or furniture that was the work of more elaborate implements than the axe and saw. The possession of gold or silver was forbidden to the citizens of Sparta and the use of iron money alone was permitted by the Lycurgean legislation. A system of sumptuary edicts and enactments was extensively developed in ancient Rome. The code of the Twelve Tables included provisions limiting expenditures on funerals. A series of laws beginning in 215 B.C. governed the materials of which garments could be made, the number of guests at entertainments and the sums to be expended on entertainments, and forbade the consumption of certain foods.

In later times, sumptuary laws were enacted in many countries of Europe. For example, in France, Philip IV issued regulations governing the dress and the table expenditures of the several orders of men in his kingdom and Charles V forbade the use of long-pointed shoes. Under later French kings the use of gold and silver embroidery, silk stuffs and fine linen was restricted. In England during the reign of Edward II a proclamation was issued against the "outrageous and excessive multitude of meats and dishes which the great men of the Kingdom had used, and still used, in their castles." Edward III in 1336 attempted to legislate against luxurious living and at the same time when costumes were regulated it was held that servants of gentlemen, merchants and artificers should have only one meal of flesh or fish per day. Another illustration may be found in 1433 in an act of parliament meeting at Perth which prescribed the manner of living of all orders in Scotland, even going so far as to limit the use of pies and baked meats to those who held the rank of baron or higher. Such legislation was brought to some of the American colonies in the 17th century. It appears, however, that most such legislation was not strictly enforced in the colonies.

In Japan sumptuary laws were passed with a frequency and minuteness of scope that had no parallel in the history of the western world. At the beginning of the 11th century an imperial edict regulated the size of houses and imposed restrictions as to materials that could be used in their construction. During the Tokugawa period sumptuary laws were passed in bewildering profusion regulating the most minute details of personal life.

In more modern times sumptuary laws have generally not gone as far as did the ancient enactments. An exception is to be found in the 18th amendment to the U.S. constitution (in effect 1919–33) that prohibited the manufacture, transport and sale of alcoholic beverages. Many additional illustrations are to be found of laws having the effect of sumptuary laws indirectly although enacted primarily for raising revenue. Excise taxes on tobacco, alcoholic beverages, jewelry, watches and other articles that are viewed as luxuries are levied in many parts of the world and are frequently defended, in part, on the ground of their beneficial moral effect.

See F. Baldwin, *Sumptuary Legislation and Personal Regulation in England* (1926). (Fr. L. K.)

**SUMTER**, a city of South Carolina, U.S., seat of Sumter County, is 40 mi. (64 km.) E of Columbia. Founded as Sumterville in 1799, and named after the Revolutionary general Thomas Sumter, it was long a typical cotton plantation village in the heart of the low-country sand hills. Furniture, lumbering, and textile industries came slowly, and the village was chartered as Sumter in 1887. It claims to be the first city to have successfully adopted, in 1912, the council-manager form of government.

Essentially a town of the new South rather than the old, it

maintains a leisurely Southern atmosphere. Wide streets are lined with oak trees covered with Spanish moss. The iris gardens in the city are known for the old cypress trees, azaleas, and camellias, as well as iris.

For comparative population figures see table in SOUTH CAROLINA: Population. (G. H. Ct.)

**SUMY**, a town and *oblast* of the Ukrainian Soviet Socialist Republic, U.S.S.R., in the northeast of the Ukraine. The *oblast* lies along the southwestern edge of the Central Russian upland from which the land slopes gently toward the Dnieper River. Area 9,382 sq.mi.; pop. (1959) 1,513,718.

Drainage of the *oblast* is by tributaries of the Dnieper, notably the Seim, Sula, and Psel rivers. In the north part its boundary lies along the Desna River, the basin of which is in the mixed forest zone, with extensive areas of marsh. South of the Seim the *oblast* is in the forest-steppe zone, but most of the former areas of oak forest have been cleared for cultivation and occupy not more than 5% of the surface. In the Desna basin soils are sod-podzols and elsewhere chernozems of high fertility. Two-thirds of the population are rural dwellers and agriculture dominates the economy.

The main crops are grains, sugar beet, tobacco, hemp, and potatoes. Sugar refining is a major industry and the beet waste helps to maintain the large number of cattle.

There are 12 towns and 20 urban districts in the *oblast*. All the towns are small, the main industry being food production. Romny, in the southwest, dates from the early 10th century. Konotop and Shostka are minor industrial centres. During World War II the area was occupied (1941–43) by German troops.

The town of Sumy, the administrative centre of the *oblast*, is on the upper Psel River, about 68 mi. SW of Kursk. Pop. (1959) 98,015. Industries include manufacture of machinery for the chemical, coal-mining and metallurgical industries, sugar refining, shoemaking, and the production of superphosphates. There is a teacher training college. Railways connect Sumy with Kharkov and the main Kiev-Kursk line. The town was founded as a Russian settlement in 1652 but there had been an earlier Slav settlement there in the 8th–9th centuries. (R. A. F.)

**SUN.** The sun is apparently the largest and brightest of the stars visible to the naked eye, but it is actually among the smallest and faintest. The illusion arises from its comparative nearness—the next nearest star is, in fact, nearly 300,000 times as far away.

### TELESCOPIC INVESTIGATION

**General Characteristics.**—The sun presents to the telescopic view a dazzling white, circular disk with a sharp edge, whose diameter is an angular distance in the sky of about  $\frac{1}{2}^\circ$ . Slight systematic variations of the angular diameter reveal that the distance from earth to sun is not constant, and that the earth's orbit is an ellipse with the sun at one of the focuses. Several methods have been employed to measure the distance of the earth from the sun in miles or other terrestrial units. The mean value throughout the year (from which the actual distance departs by less than 2%) is found to be about 93,000,000 mi. (149,664,900 km.). This is expressed astronomically by saying that the solar parallax is 8.79 (i.e., 8.79 sec. of arc), the solar parallax being the difference in direction of two ends of the earth's equatorial radius as viewed from the sun.

The sun's linear diameter, in miles, follows at once from its distance and the observed angular diameter. It is approximately 865,000 mi.—about 109 times the diameter of the earth, but much smaller than many stars, some having diameters 800 times that of the sun.

Its mass is calculated from the force of mutual attraction of the earth and sun, the mass of the earth having been independently determined (see EARTH). The result ( $2 \times 10^{33}$  g. or  $2 \times 10^{27}$  tons) is 333,000 times the mass of the earth and about at the middle of the range of stellar masses. Mass and diameter are sufficient data for the estimation of the mean density of the sun, viz., 1.41 times that of water. The density of the sun actually varies from a value in its outer layers much less than that of air to about 60 times the density of ordinary rocks at its centre.

Comparison of measurements of the positions of the stars made over long periods shows that in the direction of the constellation Hercules the stars appear on the whole to be getting farther apart; in the opposite direction (the constellation Columba), they appear to be drawing together. This indicates that the sun and the members of the solar system are moving as a group with respect to the stars.

**Surface Features.**—The mensurational characteristics are supplemented by a voluminous body of physical data. When the surface of the sun is carefully observed through a telescope it is found to present a mottled or grainy structure. The brightness of the disk is not uniform; the region near the circumference, or limb, is appreciably less bright than the centre of the disk—a fact which appears most obvious in photographs. Sunspots, which are frequently visible to the eye when viewed through a dense smoked glass, are the most easily observed markings on the sun.

A sunspot consists of a central, apparently black, umbra, surrounded by a less dark penumbra. Each of these regions is in fact

MEAN AREAS AND HELIOGRAPHIC LATITUDES OF SUNSPOTS FOR EACH YEAR 1874–1965

Areas in millionths of the visible hemisphere, heliographic latitudes in degrees

exceedingly bright, and appears dark only by contrast with the still brighter solar disk. Spots often are clustered together in groups, often in pairs or pairs of groups, and only rarely appear outside two zones on either side of the solar equator, extending about halfway toward the sun's north and south poles of rotation. The spots move steadily across the face of the sun so as to leave no doubt that the motion is caused by rotation of the sun about an axis. The sun, since it always appears circular in the sky, must be spherical, and its bright visible surface is called the photosphere. A remarkable feature of the sun's rotation is its variation with latitude; i.e., the sun does not rotate as a rigid body: the nearer its equator, the faster the rotation. Near the equator, the mean rotation period is 24.65 days; at solar latitude  $20^\circ$ , it is 25.19 days; at  $35^\circ$ , 26.63 days; and at  $60^\circ$ , 30.93 days.

Individual sunspots appear spasmodically, remain visible for periods varying from a few hours to several months and then disappear. This apparently capricious behaviour becomes a striking regularity when large numbers of spots and great lengths of time

### PHOTOGRAPHIC STUDIES OF THE SUN

1. The photosphere of the sun, showing an unusually large number of spots, faculae, and darkening at the limb (Rutherford)
2. Photograph taken in calcium light, the image of the photosphere having been artificially covered. Shows Chromosphere and Prominences (Evershed)
3. Comparison of solar spectrum with laboratory spectrum of iron (violet region). Presence of iron in the atmosphere of the sun is indicated by coincidence in positions of lines (Imperial College)
4. Spectroheliogram (photograph of sun made by monochromatic light) showing distribution of high-level calcium in the solar atmosphere (Deslandres)
5. Spectroheliogram showing distribution of hydrogen in the solar atmosphere (Deslandres)

#### STUDIES OF SOLAR PROMINENCES

1. Prominence of Sept. 21, 1939, an example of the sunspot-type classification. All detectable motions were downward (i.e., toward the surface of the sun). The photograph shows a loop formation that measured approximately 90,000 mi. in height and 105,000 mi. in width at the start of the record. The overall dimensions increased about 25% during the period of observation.
2. Sunspot-type prominence of Sept. 7, 1939, recorded in a remarkable motion-picture scene of continuous and varied activity. As the scene progressed, the general pattern became intricate, developing a background of faint gigantic loops and many small condensations moving at high velocities toward the chromosphere. The longest streamer extended more than 150,000 mi. above the edge of the sun.
3. Quasi-eruptive prominence of Aug. 24, 1939, photographed in the  $H\gamma$  of ionized calcium. The prominence was about 105,000 mi. high and extended about 155,000 mi. along the edge of the sun.
4. The same prominence as in (3), photographed the next day.
5. Prominences of the sun observed May 26, 1916, at Srinagar, Kashmir, India.
6. Inner corona and prominence photographed during a total solar eclipse May 29, 1919, observed at Sobral, Brazil. The red flame rose type of height of 130,000 mi. to more than 500,000 mi. above the surface of the sun in less than seven hours.

### CORONAE AT VARIOUS STAGES OF SUNSPOT ACTIVITY

1 Corona May 18 1901, near time of minimum sunspot activity. Characteristic of sunspot minimum with short polar brushes and long equatorial streamers.

2 Corona Aug. 30 1905, near time of maximum sunspot activity. The character of the corona is characteristic of a sunspot-maximum period and the long equatorial streamers which give it its typical form are here well developed.

3 Corona during total eclipse of June 8 1917, characteristic of maximum sunspot activity. Photograph taken at Garden Island.

4 Solar corona, Alhambra, Sp. Aug. 30, 1905. Photograph taken with 40-in. telescope, exposure time 2 1/2 seconds.

ECLIPSE OF THE SUN, JULY 20, 1963, AS PHOTOGRAPHED FROM NEW YORK CITY

PHOTOGRAPHS, (ALL) PAUL GREENWALD FROM 1963

are considered. If the number of spots appearing per year (or the total area covered by them) is plotted against time, as in the diagram, a nearly periodic relation is shown, the annual number reaching a maximum approximately every 11th year. A similar regularity characterizes the location of the spots. At a time of minimum those of a new cycle begin to appear in the higher latitudes, both north and south, of their appointed belts, and as the cycle progresses the place of outbreak gradually moves toward the equator. The thin lines in the graph illustrate this.

Sunspots are always accompanied by exceptionally bright areas on the photosphere, known as faculae. They are most easily seen near the limb, where the brightness of the photospheric background is diminished. Although they are less conspicuous than the spots, their study is equally important for an understanding of the sun.

On the comparatively rare occasions on which the sun is observed in total eclipse, small red clouds are seen apparently floating above various points on the circumference of the dark moon. They belong in reality to the sun, and are known as prominences. Prominences are not seen through an ordinary telescope in full daylight because the intense photospheric light, diffused by the earth's atmosphere and the optical parts of the telescope as by a ground glass, acts as a veil through which prominences and faint stars alike are invisible as individual objects. Prominences assume various shapes and sizes, sometimes reaching heights of hundreds of thousands of miles above the photosphere. The larger prominences can easily be seen during eclipses.

Prominences seem to be extensions of an outer solar atmosphere that is directly revealed at the beginning and ending of each total eclipse. When the moon is just covering the last remnant of the photosphere, a crescent of atmosphere remains exposed for a few seconds. It is easily seen in a small telescope as a brilliant red layer, and has been named the chromosphere.

The most striking solar eclipse phenomenon is the corona, a pearly white halo enveloping the sun and extending in more or less definite rays or streamers to distances of many solar radii. The brilliance of the corona diminishes very rapidly with distance from the sun's limb, and although its total brightness is about one-half that of the full moon, it is much fainter, area for area, than the solar prominences. No two aspects of the corona seen at different eclipses are identical; however, there is a relation between the shape of the corona and the sunspot period. At sunspot maximum the corona appears to extend equally in all directions from the sun's limb and appears round. At sunspot minimum, the poles of the sun are marked by comparatively small tufts of light, while from the equatorial regions long streamers extend to enormous distances.

A special type of telescope, called a coronagraph, can be constructed so that it diffuses almost no light and intercepts the image of the photosphere with a metal disk. On high mountain tops where diffusion by the earth's atmosphere is negligible on days of exceptional clarity, the innermost, brightest portions of the corona can be observed directly with this instrument.

### SPECTROSCOPIC INVESTIGATION

**General Considerations.**—The spectroscope is the most important of the auxiliary instruments used with the telescope for the investigation of the sun because it can select minute portions of the flood of solar radiation for intensive study. (See SPECTROSCOPY; SPECTROSCOPY, ASTRONOMICAL.)

Nearly all solar research depends at some point on a device for sorting radiation by its wavelength. This results in the familiar sequence of colours seen in the rainbow. The word spectroscope in its most general meaning is used to indicate such a device. The human eye is sensitive to only a small band out of the vast range of wavelengths represented in the total radiation of the sun, but over this restricted range, the word "wavelength" is analogous to a precise specification of colour. The spectrum, or ordered arrangement of radiation obtained from a spectroscope, of the sun's radiation consists mainly of a continuous bright background on which dark lines appear. This is called an absorption spectrum, and it confirms the direct eclipse observation that the photosphere

is covered by a layer of glowing gases. The dark lines are evidence that the glowing gases are relatively cool. A qualitative spectroscopic chemical analysis of the sun's outer envelopes may be made by comparing the positions, or wavelengths, of the absorption lines with those of emission lines produced by known substances in the laboratory. In this manner the presence on the sun of 67 elements known on earth, and 18 chemical compounds, has been established. The spectroscopic chemical analysis of the sun can also be made quantitative by directing attention to the total amount of radiation extracted from the continuous background by the dark lines. The darkness of a line is related in a complicated way to the amount of material that produces it, but with the aid of laboratory calibrations of line strengths, the relative abundance of the chemical elements has been determined for the sun. The chemical constitution of the sun resembles that of the earth, with the exception that the lighter elements, especially hydrogen and helium, account for almost all its mass.

The spectrum of individual features of the sun may be studied, as well as the light of the entire solar disk. Just at the start of, or just before the end of, the total phase of a solar eclipse, when the chromosphere still remains exposed for a few seconds, the spectrum of its light shows bright rather than dark lines, since this layer of the sun is semitransparent and there is no bright photospheric background to provide a source of radiation to be absorbed. Because of its evanescence, this spectrum is known as the flash spectrum, and it is essentially identical with the absorption spectrum in the position of its lines. The heights reached by the various substances have been determined from special observations at such times. The majority are confined to the lowest atmospheric layers, not more than 500 mi. high, near the top of the photosphere or the bottom of the chromosphere. Hydrogen, helium, and ionized calcium can be traced to great heights, extending up to 8,000 or 9,000 mi. The radiation of hydrogen is the source of the intense red colour of this part of the sun's atmosphere—the chromosphere.

The chromosphere is so bright when viewed during a solar eclipse that it seems reasonable to expect success in the observation of its bright-line spectrum in full daylight. The observation is difficult because the photospheric light diffused by ordinary telescopes and the earth's atmosphere spreads over and drowns the chromospheric radiations. Nevertheless, the hydrogen and helium emission lines are easily observable with very modest telescopic and spectroscopic equipment, but the fainter lines can be seen only with very powerful instruments fed by clean (nondiffusing) telescopes, such as the coronagraph, and located where the scattering of light by the earth's atmosphere is as small as possible.

When the spectroscope is directed toward the corona, at eclipse time or with the aid of a coronagraph, it is found that a great deal of the coronal radiation yields the ordinary solar spectrum and seems to be only reflected sunlight. Actually, radiation from the corona contains four main components: a continuous spectrum which is sunlight scattered by electrons; an absorption spectrum, which is sunlight diffracted by interplanetary dust particles; a series of bright emission lines which have not yet been produced in terrestrial laboratories; and radiation that can be detected using radio methods. The bright emission lines of the corona can be identified with radiations emitted by isolated and very highly ionized atoms of iron, nickel, and calcium (see CORONA).

**Spectra and Physical Conditions.**—The spectrum of the solar corona is one of the best examples of the results of physical conditions in modifying the radiation emitted from various regions of the sun. After the effects on line spectra of temperatures, pressures, magnetic and electric fields, and motions of the sources of light had been established through terrestrial spectroscopic studies, these and other physical parameters could be investigated on the sun by means of detailed investigation of the solar spectrum lines. Three of the more important applications to the sun have produced knowledge of temperatures, magnetic fields, and motions.

An early spectroscopic laboratory result classified spectrum lines into high-temperature and low-temperature lines. This classification had an important application when spectra of the photosphere and of a sunspot were compared. The spectrum of a spot

contains evidence of compounds, of which only the separated elements contribute to the photospheric spectrum, and the spot spectrum shows a strengthening of low-temperature and a weakening of high-temperature lines when compared with the spectrum of the photosphere. The conclusion is that the sunspot region has a temperature  $2,000^{\circ}\text{C}$  lower than the rest of the solar atmosphere.

A source of light placed in a magnetic field (*i.e.*, a region such as the neighbourhood of the poles of a magnet) has many of its spectrum lines split into a number of component lines, lying closely side by side. Unless the field is very strong, the components are too close together to be seen as distinct individual lines, but the original line may appear to be broadened. By means of special appliances very slight broadenings produced by weak magnetic fields can be detected. The lines in the spectrum of a sunspot show just the composite character that would result from the existence of a magnetic field in the spot in a direction perpendicular to the sun's surface.

Many years of observation show that all sunspots are magnets, some presenting a north, others a south pole to the surrounding space. In each pair of spots, or spot groups, the leaders and followers in the journey around the sun's axis have opposite polarities. Many apparently single spots have invisible companions which can be found by the magnetic splitting of the spectrum lines.

There is a reversal of polarity in the southern solar hemisphere with respect to the northern; thus, if the leader of a pair were a north pole in the northern hemisphere, it would be a south pole in the southern hemisphere, and vice versa; and, with few exceptions, this order would characterize all spots from one minimum to the next of a sunspot cycle. During the next cycle this order would be reversed, so that the approximate period from north pole preceding in the northern hemisphere to north pole preceding in the northern hemisphere is 22 years, just twice the interval between sunspot maxima.

More refined investigations have shown that weak magnetic fields are widespread over the solar surface. At times, these fields, which are much weaker than those of the spots, and generally only a few thousandths of the field in extremely large spots, give the impression that the sun as a whole is a magnet like the earth. (*See GEOMAGNETISM.*) Continued observation of the sun's weak fields has shown that they vary in a complicated, quite disorganized fashion and produce no resultant general magnetic field for the sun. Among the weak fields, the stronger show a gross structure closely related to the forms of the facular regions, but there is no obvious connection between brightness variations, motions, and the general background of weak fields in the photosphere.

Relatively rare measurements of magnetic fields in the chromosphere indicate a weak correlation between magnetic fields and motions in this layer of the solar atmosphere. A fairly close relationship between brightness, motions, and magnetic fields may exist in the corona, but the technical difficulties of achieving direct, simultaneous observation of these quantities are enormous.

The effect on a spectrum line of relative motion of the source and observer along the line of sight (*see* DOPPLER, CHRISTIAN JOHANN; SPECTROSCOPY, ASTRONOMICAL) has had many and varied applications. The amount and direction of displacements of the spectrum lines relative to their normal positions indicate velocities of approach or recession.

Spectroscopic measurement of line shifts in stellar spectra has been used to find the speed of the sun's motion among the stars. Analysis of the line displacements shows that the solar system is moving at a speed of 12 mi. per second with respect to the local stellar system.

Another application to the sun consists in the observation of line shifts in spectra of the east and west limbs of the sun. These show that the east limb is approaching the earth and the west limb receding. The deduced values of the speed of rotation agree very well with those indicated by the spots, and the spectroscopic observations can be extended beyond the narrow belts to which the spots are confined. Similar spectra can be used for determining what lines in the solar spectrum properly belong to the sun, and which are produced by absorption in the earth's atmo-

sphere. The atmosphere of the earth contains much water vapor and other constituents that produce many absorption lines. These are not only intermingled with the solar lines, but are crowded closely together in long ranges of the spectrum that no sunlight at all reaches the earth in these wavelengths. Such lines, however, occupy identical positions in the spectra of the two solar limbs and are therefore readily distinguished from the displaced lines of the sun.

One of the most difficult and important applications of the shifts arising from motions along the line of sight seeks to detect atmospheric currents in the sun. Solar storms sometimes occur of incomparably greater fury than the hurricanes and tornadoes of the earth, but quite inconsequential as far as the sun is concerned, and the stormy motions of the solar atmosphere are revealed by distortions and displacements of the spectrum lines. Prominences are sometimes ejected from the sun as a result of such activity, and bits of the solar atmosphere can be projected from sun to earth, where they may produce auroras and magnetic storms. However, there are systematic movements which have been observed, and of these perhaps the most interesting are those occurring near sunspots. At the lower atmospheric levels gases move upward and outward from a spot, while in the higher levels the movements are inward and downward, as if a spot were a sort of whirlpool into which the high-level gases are drawn. Indeed there is definite evidence of high-level circulatory movements around the axes of spots, which points strongly to the same conclusion.

Away from the spots, the solar atmosphere is in a constant, random, bubbling motion in rather strong contrast to the organized movement enforced by a sunspot region. Close to sunspots and their surrounding faculae, the bubbling, or twinkling, motions of small regions in the solar surface are strongly suppressed, possibly because of the action of magnetic fields.

#### SPECTROHELIOGRAPHIC INVESTIGATION

The spectroheliograph is an instrument that uses a spectroscope as a light filter to reject all radiation but that in the centre of a dark absorption line or other small regions of the spectrum. The radiation transmitted by a spectroheliograph is used to form a monochromatic picture of the sun. (For construction and method of operation of this instrument, *see* SPECTROHELIOGRAPH.) A variant of the spectroheliograph, the spectrohelioscope, can be employed for direct visual examination of the sun using light from any selected wavelength in the visual part of the spectrum.

Somewhat similar photographs and views of the sun can be obtained through polarizing monochromatic filters, or multilayer interference filters. These devices are used to select small regions of the spectrum, and may be properly regarded as forms of the spectroscope in the general sense. The filters transmit a complete picture rather than dissecting it into lines and then reassembling it as is the case in the spectroheliograph, and they have found wide application in the production of monochromatic solar pictures.

The observation of the solar atmosphere with the instruments mentioned points the way to a fairly complete knowledge of the appearance of the sun in the radiation of various spectral lines and regions of the continuous spectrum. The observations verify and extend the evidence of the complicated structure of the sun which the ordinary telescope provides. The upper part of the sun's atmosphere is composed of minute prominences that form, disappear, and re-form repeatedly, so that on the average the monochromatic view of the sun shows a rather permanent twinkling. In the region of spot groups, bright plage regions, and the monochromatic aspects of the faculae, are revealed, and the spectroheliographic studies have shown that sunspots always appear only in the plages. The plages form before the sunspots appear and persist long after the spots have vanished.

Solar flares, the sudden, short-lived brightenings of small parts of the solar surface, also appear only in plages. The word "sudden" must be emphasized in the definition of a flare since the larger plage regions often change brightness at a slow rate. Among the markings on the sun's surface, revealed by monochromatic observation, flares are the most significant from the standpoint of

the direct effects of the sun on earth. The outbreak of a flare, visible in hydrogen light and accompanied exactly at the start of the visible disturbance by a sudden large increase in the solar radiation in the radio region of the spectrum, often is followed by a magnetic storm on earth after a delay of one to three days. Magnetic storms are accompanied by auroral displays, and it is assumed that the flares in some way eject nuclei of hydrogen atoms or protons) and electrons and these, traveling at rather modest speeds of 400 to 600 mi. per second, impinge upon the earth's atmosphere about 50 hours after the flare outbreak to produce the observed terrestrial disturbances. The connection between solar flares and the electrical equilibrium of the earth's ionosphere has been established so firmly that observations of the flares are important elements in the prediction of favourable or unfavourable conditions for the sending of long-distance radio messages. See also INTERNATIONAL GEOPHYSICAL YEAR.

### INVESTIGATION OF THE SUN'S RADIATION

**The Sun's Total Radiation.**—Of the  $3.9 \times 10^{33}$  ergs emitted by the sun every second in the form of electromagnetic radiation, its attendant planets and their satellites receive about 1 part in 170,000,000, so that the significance of the process is primarily cosmic, even though of dominant importance for the thermal environment of the earth. The first step in seeking further knowledge of this fundamental process is the measurement of the rate of radiation with as great precision as possible. Various instruments must be used in this endeavour, since one must measure X-rays, ultraviolet radiation, light, infrared radiation, and radio emissions.

Only the radiation received by a small area near the earth can be measured, but, knowing the dimensions of the solar system, the total amount can be deduced. A general method is to convert the sun's radiation into heat, which can be accurately measured. The result is called the solar constant: the amount of energy which would fall perpendicularly per square centimetre per minute on a surface placed outside the earth's atmosphere at the earth's mean distance from the sun. The value of this constant is about 2.0 cal.

The results of measurement of the solar constant can be combined with similar laboratory measurements for obtaining an estimate of the sun's temperature. Extrapolations from experiment have shown that an ideal emitter of electromagnetic radiation—a black body—would radiate energy at a rate strictly proportional to the fourth power of its temperature. The assumption that the sun radiates like a black body is an oversimplification, yet it makes possible a temperature estimate which is an important clue to solar radiative processes. Since the sun is visible, energy is flowing out of it from hotter to cooler regions, and it cannot be uniform in temperature. It is necessary to consider what region of the sun has the temperature that is determined by the black-body assumption. Because the greatest part of the radiation is in the form of light, this region must be the photosphere: the relatively thin visible surface of the sun, and the temperature estimated from the total radiation is that of this layer. The temperature is called the effective temperature, and has a value of  $5,800^\circ \text{K}$  (absolute centigrade degrees).

**The Sun's Analyzed Radiation.**—The same instruments that are used in the measurement of the sun's total radiation can be employed in other ways to provide data for a slightly different method of estimating a temperature of the sun. The radiation from a black body is distributed among the various wavelengths in its continuous spectrum in a manner definitely related to the temperature. Therefore, if a photoelectric cell be passed along the solar spectrum, and the amount of energy at each point in the continuous background be measured, the distribution of energy throughout the spectrum is obtained and the absolute temperature follows. There are several methods of analyzing such observations to derive a temperature, and values are obtained in the range  $4,500^\circ$  to  $6,300^\circ \text{K}$  (absolute). If the sun radiated exactly like a black body, the several temperatures would agree with one another and with the result obtained from the solar constant. The slight departures from agreement indicate that the sun is not quite in the ideal equilibrium demanded for a black body, but

is sufficiently close to ensure that the physical phenomena near its surface are similar to those expected in an enclosure at a temperature of  $5,000^\circ$  to  $6,000^\circ \text{K}$ .

Although the assumption of black-body conditions provides a close representation of measurements of radiation made with ordinary and infrared light, there are two regions of the spectrum which are extraordinary in appearance and show large differences from expectations based on a solar model radiating perfectly at a temperature of  $5,000^\circ \text{K}$ . The two regions are: in the extreme ultraviolet, where observations must be made from rockets, or other space vehicles, far above the earth's atmosphere; and in the radio region, where special types of antennae and receivers make investigation possible from the earth's surface.

**The Sun's Radiation in the Extreme Ultraviolet.**—In the extreme ultraviolet (wavelength less than  $0.00015 \text{ mm.}$ ), the continuous background of the sun's spectrum is undetectable and only bright lines appear. The principal line is the fundamental line of hydrogen. The character of this line indicates that it is formed in a region of the chromosphere where the temperature is increasing rapidly with height above the photosphere. Other bright, high-temperature lines are present to support this deduction. Thus the chromosphere, which is the source of the bright lines in the extreme ultraviolet part of the solar spectrum, is a most unusual region, in which the temperature increases with distance away from the sun, and atoms are observed in motion at unexpectedly high speeds.

**The Sun's Radiation in the Radio Region.**—The result derived from the observations in the extreme ultraviolet is confirmed by measurements of the sun's radio radiation. In the ultraviolet part of the solar spectrum the wavelengths of solar radiation are less than  $0.00015 \text{ mm.}$ ; in the radio region the wavelengths are in the range  $5 \text{ mm.}$  to  $10,000 \text{ mm.}$  The shortest wavelengths originate near the base of the chromosphere, but the longest can only come from far out in the corona. Energy observed at the various wavelengths can be equated to the energy radiated from a black body of the same size as the sun's visible disk in order to derive an apparent temperature. Apparent temperatures, based on measurements of the radio energy received from the sun, range from about  $6,400^\circ \text{K}$  for the shortest waves originating in the chromosphere near the sun's visible surface to  $1,200,000^\circ \text{K}$  for wavelengths of tens of metres originating entirely in the solar corona, more than  $1,000,000 \text{ mi.}$  above the visible surface.

On earth lightning flashes are the only natural sources of radio waves, but there are at least five different kinds of radio energy generated on the sun: (1) The continuous, nearly invariable component from which the apparent temperatures are computed; (2) The continuous and steady contribution that is associated with the presence of plages on the sun's visible surface; (3) Erratic increases in energy of very short duration, but following closely upon one another, often so closely that they overlap; these may be accompanied by an increase in the steady component; (4) Sudden, very great, nonrecurrent increases beginning at the start of solar flares and associated with them; (5) Occasional isolated increases of very short duration. Sometimes the variable portion of the sun's radio energy quite overwhelms the continuous background. This is completely different from the situation in the visible spectrum, where the variable features are difficult to detect. See also TELESCOPE, RADIO.

### THEORIES OF SOLAR STRUCTURE AND EVOLUTION

**Structure of the Sun.**—A mathematical model of the structure of the sun can be based on data from observations similar to those described above, and data from terrestrial physics laboratories dealing with the behaviour of matter at temperatures, pressures, and densities that range from the extremely high to the almost vanishingly small. According to these models, the temperature at the centre of the sun is about  $20,000,000^\circ \text{K}$ . Going out from the centre of the sun toward the surface about  $4,200^\circ \text{K}$  is reached at the very top of the photosphere. In the chromosphere the temperature starts to rise, at first very slowly and then more rapidly, until at the beginning of the corona, about  $9,000 \text{ mi.}$  above the photosphere, the temperature is  $500,000^\circ \text{K}$ . In the

outer parts of the corona, 1,500,000 mi. from the centre of the sun, the radio observations are best fitted by a temperature of 1,500,000° K. Pressures start at 6,000,000,000,000 lb. per sq.in. at the centre, decrease to about atmospheric near the visible surface, and become inappreciable in the upper chromosphere and corona. The mathematical model indicates that 99% of the mass of the sun is concentrated within 0.6% of its radius; thus, the density of the sun decreases rapidly away from the centre.

Only the most elemental forms of matter can exist at the temperatures encountered near the centre of the sun. Atomic nuclei must be stripped almost bare of their satellite electrons and the rates of motion of the elementary particles must be in the range 100 to 1,000 mi. per second. All of the bits of matter—electrons, neutrons, and protons—that exist at the sun's centre participate in a process of continual interchange of energy between radiation and motion of particles. But there is an important difference in the behaviour of the atoms and electrons on one hand and the radiation on the other. The motions of the particles are kept within a limited range by the gravitational equilibrium of the whole sun, while electrostatic forces preserve a constant proportion between the number of nuclei and the number of electrons in each region. Radiation, however, is not so controlled. It works its way from the centre, where it is most intense, out to the surface and thence to space at the observed rate of  $3.8 \times 10^{33}$  ergs per second. The sun loses radiation at this prodigious rate, and has been doing so for many millions of years, while the electrons and atomic nuclei remain chained within its boundaries.

**Source of the Sun's Radiation.**—It has been realized for many years that the observed rate of energy loss by leaking of radiation from the solar surface must be balanced rather exactly by the rate of energy generation in the interior, since there is little evidence that the sun is heating or cooling rapidly. Because other sources of energy are insufficient, astronomers have sought a series of nuclear transformations which would liberate radiation at the required rate. The transformation of 1% of the sun's mass from hydrogen to helium supplies enough energy to keep it shining for fully 1,000,000,000 years. There are other conditions that must be satisfied in the selection of possible energy sources. The sun must not only be in balance as regards the flow of radiation; it must simultaneously be in mechanical equilibrium. The pressure, which is primarily determined by the temperature, must exactly balance the weight of the overlying layers at every point throughout the sun. Restrictions such as these on the possible choices have directly led to the conclusion: fusion between hydrogen nuclei, or protons, to produce helium is the source of the sun's energy. The discovery of a satisfactory means of generating the required enormous energies and advances in knowledge of nuclear reactions have made possible the computation of a probable course of evolution for the sun.

**Mathematical Models of Detailed Features of the Sun.**—The general concepts involved in the computation of plausible models for the interior of the sun and the choice of a method of energy generation, if complete, would imply the existence of sunspots, the chromosphere and the prominences, the plages and the flares, the corona, the weird law of solar rotation, the magnetic fields—in short, all of the detailed and transient features that still require continuous observation. Considerable progress has been made in the study of solar details, but mutually consistent theories for the different structures do not exist. Perhaps a reason can be found in the realization that the observed deviations from equilibrium represent trifling phenomena on a solar scale, despite their remarkable effects on earth, and the idea of the sun as the perfectly calm, unchanging star of the mathematician and poet is an amazingly good approximation to the truth. See also STAR; and references to "Sun" in the Index.

**BIBLIOGRAPHY.**—General accounts of the sun are contained in Giorgio Abetti, *Solar Research* (1963); W. M. Baxter, *The Sun and the Amateur Astronomer* (1963); A. Dauvillier, *Physique Solaire et Géophysique* (1962); G. Gamow, *A Star Called the Sun* (1964); D. H. Menzel, *Our Sun*, rev. ed. (1959); H. W. Newton, *The Face of the Sun* (1958); for more technical treatment see R. J. Bray and R. N. Loughhead, *Sunspots* (1964); J. W. Evans (ed.), *The Solar Corona* (1963); G. P. Kuiper (ed.), *The Sun* (1953); M. R. Kundu, *Solar Radio As-*

*tronomy* (1965); H. J. and E. v. P. Smith, *Solar Flares* (1963); R. Thomas, *Physics of the Solar Chromosphere* (1961); A. Unsöld, *Physik der Sternatmosphären* (1955). (H. D.; O. C. M.)

**SUNBIRD**, a group of small perching birds of more than 100 species forming the family Nectariniidae. They are the Old World counterparts of the hummingbirds. Africa is richest in species, then southern Asia, nearby islands, and Australia. They are forest-, brush-, and garden-dwelling birds. The males of many species have brilliant colours; iridescent blues, purples, and greens with patches of yellow, red, and black are common. However, some species are dull coloured, as the females usually are.

Sunbirds are characteristically flower birds, fitting about and perching among blossoms, probing into the flowers for small insects and nectar. For this they have long, slender, curved bills and extensible, more or less tubular tongues. The usual type of nest is an oval, hanging structure attached to a twig. The entrance is at the side near the top, over which a roof projects. The eggs are usually spotted and two in number. (A. L. R.)

**SUN BITTERN**, a bird, *Eurypyga helias*, of Central and South America, placed in a family by itself, the Eurypygidae. It is distantly related to such birds as the kagu of New Caledonia and the rails and cranes and is grouped with them in the order Gruiformes. The sun bittern is a slender bird about 17 in. long, somewhat rail-like but with full wings; a long, ample tail; and plumage variegated with browns, yellows, black, and white. In courtship, its beautifully marked golden wings and tail are fully spread. It lives on the ground in wet forests and feeds on insects. The flight is buoyant. It builds a bulky nest in trees and lays two or three rust to brownish eggs, with darker blotches. (D. W. A.)

**SUNBURY**, the seat of Northumberland County, Pa., U.S., is an industrial and agricultural centre on the Susquehanna River, 40 mi. (64 km.) N of Harrisburg, on the site of an old Indian village. Sunbury was surveyed in 1772, incorporated as a borough in 1797, and became a city in 1922. Ft. Augusta, erected 1758, where the French were defeated during the French and Indian War, and the nearby home of Joseph Priestley, the discoverer of oxygen, are tourist attractions. In July 1883 Thomas Edison began operating in Sunbury the world's first three-wire central electric-lighting station. For comparative population figures see table in PENNSYLVANIA: *Population*. (A. J. P.)

**SUNBURY-ON-THAMES**, an urban district in northwest Surrey, Eng.; until 1965 it was in the former Middlesex County. It comprises Sunbury, Sunbury Common, Ashford Common, Charlton, Littleton, Shepperton, Shepperton Green, and Upper and Lower Halliford. Pop. (1961) 33,437. The district has a frontage to the River Thames of about eight miles. A vast reservoir of the Metropolitan Water Board is at Littleton, and other properties of the board and of the Thames Conservancy are elsewhere in the locality. Sand and gravel are excavated on a considerable scale. There is an extensive petroleum research centre in the district. Large film studios are at Shepperton, and race meetings are held at Kempton Park. Some market gardening is carried on.

Thomas Love Peacock, the poet and novelist, who lived in Lower Halliford for many years, is buried in Shepperton Cemetery.

**SUNDA ISLANDS AND STRAIT.** The Sunda, or Sunda Islands extend from the Malay Peninsula to the Moluccas and include the Greater Sunda Islands (Sumatra, Java, Borneo, Celebes, and adjacent smaller islands) and the Lesser Sunda Islands (Bali, Lombok, Sumbawa, Sumba, Flores, Timor, Alor, Wetar, etc.). With the exception of Borneo, eastern Sumatra, and nearby areas they belong to the geologically unstable zone of island arcs, under sea ridges and active volcanism lying between Asia and Australia. The Sunda Islands include most of the land area of Indonesia. Only northern and northwestern Borneo and eastern Timor are not under Indonesian political control. Malaysian cultures and languages predominate in the area.

Sunda Strait separates Java and Sumatra. At its narrowest the island of Sangiang divides it into two channels, each about 10 miles wide. Although overshadowed in commercial and strategic significance by Malacca Strait, it remains an important passage uniting the Indian Ocean and eastern Asia. The spectacular eruption of Krakatau (q.v.) took place in Sunda Strait in 1883.

See also **INDONESIA, REPUBLIC OF** and articles on the individual islands. (J. M. Br.)

**SUN DANCE**, the most spectacular and important religious ceremony of the Plains Indians (*q.v.*) of the 19th century. Ordinarily held by each tribe once a year in early summer, it was an occasion when all could gather with guests from other tribes and reaffirm their basic beliefs about the universe and the supernatural through words, ceremonies, and symbolic objects.

The ceremony was most highly developed among the Arapaho, Cheyenne (*qq.v.*), and Oglala Sioux (and may have originated with these tribes). By the end of the 19th century, it had spread with local variations to include most (26) of the tribes from the Plains Ojibwa in Saskatchewan south to the Kiowa (*q.v.*) in Texas. The sun dance is a good example of the many individual quests for power or aid from the supernatural that became elaborated as tribal ceremonies. In many instances it was a private experience involving just one votary, or a small group of them. The development of total tribal participation, widespread co-operative effort, direction by such officials as tribal leaders and shamans, and elaboration beyond the immediate sun dance indicate the meaning of this ceremony in terms of tribal aspirations (secular and religious) and in the reinforcement of social control.

In the most elaborate versions a great camp circle was formed, preliminary instruction was given to the pledger and his associates, necessary supplies were gathered, and a dance structure was erected with a central pole to symbolize a source of supernatural power (*e.g.*, the sun). Preliminary dances by others and the erection of an altar were followed by the sun dance itself. This continued intermittently for several days and nights; during this time those dancers who were fulfilling a vow or seeking power neither ate nor drank, their sacrifice ending in frenzy and exhaustion (among some tribes in self-torture and mutilation). In one version skewers tethered to the central pole were thrust through the flesh of the dancer's breast or back and torn away to end the rite, the camp site then being immediately abandoned.

In an effort to curb such practices the U.S. government outlawed the sun dance (1904). Among some tribes benign forms of the ceremony continued, usually as part of Fourth of July celebrations. A few tribes, however, have attempted to revive the sun dance in its original form and meaning.

Jones, "The Sun Dance of the Northern Ute," *Bureau of American Ethnology Bulletin* 157 (1955). (W. H. Ke.)

**SUNANESE**, a highland people of West Java (Republic of Indonesia), numbering about 12,000,000. Historically they were first recorded under the Indo-Javanese Brahmanical states (8th century A.D.) and subsequently accepted the Mahayana (*q.v.*) Buddhism adopted by the Shailendra kings (*see* **JAVA: History**). Muslim trade influenced them to accept Islam in the 16th century, the people of Bantam (*q.v.*) being especially fervent; however, animistic and Hindu influences survive.

The Sundanese village is ruled by a headman and a council of elders. Single-family houses of wood or bamboo are raised on piles. Close to the settlement are individually owned lands largely devoted to terraced rice fields. Rice culture and ironworking, as well as marriage, birth, and death ceremonies, conform closely to the Indonesian pattern, although often mixed with elements of more elaborate Indian ceremonies.

The opening of roads into the highlands, development of government- and foreign-owned plantations, and the establishment of village schools tended to erase differences between other Javans and the Sundanese. They have spread into neighbouring districts of Java and into the Lampong area of southern Sumatra.

(F.-C. Ce.; P. E. de J. de J.)  
Except for Javanese, the most widely spoken Malayo-Polynesian language is Sundanese (with a number of dialects; that spoken in Priangan Province has the highest prestige). Like Javanese,

Sundanese has status styles: *kasar* (informal), *lemes* (deferential), and *panengah* (a middle style). The Javanese alphabet (the earliest used to write Sundanese) and one adapted from Latin are most commonly employed. A modified Arabic system is usual in religious writings. Publication in Sundanese has been meagre, the major city of Bandung (*q.v.*), for example, having only one newspaper. The limited Sundanese literature is strongly affected by that in Javanese. See also **JAVA: Population**. (I. Dn.)

Wales, *The Making of Greater India* (1951); E. M. Uhlenbeck, *A Critical Survey of Studies on the Languages of Java and Madura* (1964).

**SUNDARBANS** (formerly **SUNDEBUNDS**), a tract of country in the India-Pakistan subcontinent, forming the seaward fringe of the Gangetic Delta. It extends for about 170 mi. (274 km.) along the coast of the Bay of Bengal, from the estuary of the Hooghly River (India) on the west to that of the Meghna (East Pakistan) on the east. It is intersected from north to south by large tidal rivers or estuaries, which are connected by numerous interlacing channels. The whole tract is a network of estuaries, rivers, and creeks, which enclose a large number of flat, marshy islands. Most of these are covered with forest standing in soft mud, usually under water at high tide. Formerly the Sundarbans ran inland from 60 to 80 mi. (97 to 129 km.). The characteristic tree is a large mangrove, the sundari (*Heritiera littoralis*), from which the name of the tract probably derives. Along the coast the forest passes into a mangrove swamp of other, smaller species, which in some places is separated from the sea by a line of sand dunes. South of the northern area of cultivation the Sundarbans are almost uninhabited, but wild animals are numerous, and crocodiles infest the estuaries. (L. D. S.)

**SUNDARGARH**, a town of Orissa state, India, and the headquarters of the district of the same name, is 45 mi. (72 km.) N of Sambalpur and 120 mi. (193 km.) SW of Ranchi. Pop. (1961) 11,329. The town has a science college affiliated to Utkal University in Cuttack.

**SUNDARGARH DISTRICT** (area 3,571 sq.mi. [9,715 sq.km.]; pop. [1961] 758,617), created in 1949 by the merger of the former princely states of Gangpur and Bonai, occupies the northwestern part of Orissa and is bounded west by Madhya Pradesh and north and east by Bihar. Gangpur is a plateau 700 ft. (213 m.) above sea level with a belt of forest in the north. Bonai is a thickly wooded region surrounded by low hills. The chief rivers are the Ib, the Samkha, and the Koel. The majority of the population is engaged in agriculture, and the main crops are rice, pulses, mustard, gram, sugarcane, potatoes, and jute. The district has valuable deposits of coal, iron ore, limestone, manganese, and dolomite, however, and is rapidly being industrialized. The main industrial centre is the town of Rourkela (pop. [1961] 90,287), the site of the Hindustan steel plant. Built with aid from West Germany, the plant has an annual output of more than 1,000,000 tons of steel. (MA. M.; N. K. S.)

**SUNDAY, BILLY** (WILLIAM ASHLEY SUNDAY) (1862–1935), U.S. evangelist, whose sermons gave vivid expression to the emotional upheaval caused by the transition from a rural to an industrial society in the United States, was born at Ames, Ia., on Nov. 19, 1862. The son of a brickmason who died a private in the Union Army (1862), Sunday spent four years in an orphan's home, grew up on a farm, completed high school, and worked as an undertaker's assistant before entering professional baseball in 1883. He gave up baseball in 1891 to become a YMCA worker. From 1896 until his death he conducted religious revivals in major cities throughout the United States. He was ordained in the Presbyterian Church in 1903. His theology was Fundamentalist.

Following in the footsteps of Dwight L. Moody (*q.v.*), and with the aid of a choir leader, Homer A. Rodeheaver, and a score of revival "specialists," Sunday conducted more than 300 revivals with an estimated total attendance of 100,000,000. Sunday claimed that 1,000,000 "hit the sawdust trail" to profess their conversion; he received more than \$1,000,000 in "free-will offerings." Despite his sensationalism, Sunday was enthusiastically supported by the evangelical churches and by influential laymen. He played

a prominent part in the prohibition movement and reached the peak of his fame in 1917 in his New York City revival. He died at Chicago, Ill., on Nov. 6, 1935. See REVIVALISM.

**BIBLIOGRAPHY.**—Elijah P. Brown, *The Real Billy Sunday* (1914); William T. Ellis, *Billy Sunday: the Man and His Message* (1936), which contains Sunday's brief autobiography; Homer A. Rodeheaver, *Twenty Years with Billy Sunday* (1936). The only analytical study of Sunday's career is that of William G. McLoughlin, Jr., *Billy Sunday Was His Real Name* (1955). (W. G. McL.)

**SUNDAY**, the first day of the week, called in Christian terminology the Lord's day (*kyriake* in Greek and *dies dominica* in Latin; hence *domenica* in Italian, *domingo* in Spanish, *dimanche* in French). But it is not the Lord's day in the same sense as the Jewish sabbath (*q.v.*), on which the sovereign lordship of God is acknowledged by abstention from work. Sunday is the day not of Yahweh but of Christ, the Lord in virtue of his resurrection from the dead (hence the Russian word for Sunday, *Voskresenye*, derived from the word for "resurrection"). Sunday is the weekly memorial of the Easter mystery and of the rebirth of Christians, the day both of Christ the Lord and of the people whom he bought with his blood. The essence of its celebration is the gathering of the baptized around the Lord's table (see EUCHARIST; LITURGY; MASS). Thus the Constitution on the Sacred Liturgy (1963) of the second Vatican Council says: "The Lord's day is the original feast day," which should be observed "as a day of joy and of freedom from work."

**The Weekly Easter.**—The keeping of Sunday is based on the Gospel accounts of the resurrection of Christ and his first appearance to his disciples thereafter. It was on "the first day of the week" that the Lord rose again (Matt. 28:1; Mark 16:9; Luke 24:1; John 20:1) and showed himself to his friends; that he was recognized by the disciples at Emmaus "in the breaking of the bread" (Luke 24:35); and that he appeared among the assembled apostles, ate with them (Luke 24:41-43), and said to them "As the Father has sent me, even so I send you" (John 20:21-23). The first commemoration of the resurrection took place eight days later (by biblical methods of counting), on the following Sunday, when the disciples were met together and Jesus showed himself again, stood among them, and invited Thomas to place his hand in his wounded side (John 20:26-27).

The apostolic generation at once grasped the importance of the first day, linked to the remembrance and the presence of the risen Lord. St. Paul, writing at Easter in about the year 57, connects the collection for the brethren in Jerusalem with the weekly meeting (I Cor. 16:2), and in Acts there is a description of the group with Paul at Troas on "the first day of the week, when we were gathered together to break bread" (Acts 20:7). Before the end of the 1st century A.D., the author of Revelation gave the first day its name of the "Lord's day": "I was in the Spirit on the Lord's day" (Rev. 1:10).

But Easter for Christians is a day not merely of remembrance but also of hope. For this reason the Lord's day has always been kept as an anticipation of the return of Christ in glory; the Lord's Eucharist brings together the royal and priestly people until he comes (I Cor. 11:26). The church fathers therefore called Sunday the eighth day. In the words of St. Augustine, "The day which was first shall be the eighth, so that the first life will not be taken away but made eternal." After the present age, with its rhythm of seven days in the week, comes the eternal day, the day beyond weeks, the day of the consummation of Easter.

**The Day of the Church.**—Sunday is the church's day, because on it the people of God meet together. The text from Acts quoted above shows the local community thus assembled. A little later (perhaps late 1st century A.D.) the author of the *Didache* said, "Having met together on the Lord's day, break bread and give thanks." Justin (mid-2nd century) gave the first description of this liturgical assembly: "On the day called the day of the sun all our people living in town or country meet together in one place. The memoirs of the apostles are read, or the writings of the prophets." After the reading of the Word of God came the homily of the presiding minister, common prayer, and the celebration of the Eucharist.

As the day of the church, Sunday is also the day of baptism (as

can be seen from the *Apostolic Tradition* of Hippolytus, written at the beginning of the 3rd century), of ordinations, and of church dedications. Baptism marks the entry of newcomers into the people of God, represents the death and resurrection of Jesus Christ (Rom. 6:3-5), and is the first moment of Christian initiation which is achieved in communion at the Saviour's meal celebrated in the Lord's assembly.

**A Day of Joy.**—As the weekly Easter, and the day of the Saviour and of his church, each Sunday ought to be full of joy and charity; hence the early custom of standing to pray (no longer entirely observed in the West) and of not fasting on Sunday. "On Sunday be always joyful, for he who is afflicted on Sunday commits a sin," says the 3rd-century *Didascalia apostolorum*. This command is echoed by the whole church tradition. (Pl. J.)

**Sunday Observance.**—In the early church, which had no legal standing in the Roman Empire, Sunday was a day not only of joyful worship but also of ordinary work. Constantine I introduced the first civil legislation (321) making Sunday a day of rest when he decreed the cessation of work on Sunday for the legal profession and for townsfolk, though farmers were not compelled to remain inactive because of the dependence of agriculture on the weather. This law, aimed at providing time for worship, was followed later in the same century and in subsequent centuries by further restrictions on Sunday activities.

At first no connection was made between the Jewish regulations governing the sabbath and the Christian laws of Sunday abstinence from work, but parallels between them began to be drawn in the 6th century and by the 9th century the commandment in the Decalogue which forbids work on the sabbath was explicitly cited in a Roman synod as a justification for undertaking no servile labour (*i.e.*, such as a slave would do) on Sunday. There was no identification of the sabbath with Sunday in the medieval West, however, and the parallel was not pushed to its logical conclusion until after the Reformation in some Protestant countries. Hence Sunday in Roman Catholic countries tends to be a day of both worship and enjoyable recreation.

The great Reformers themselves, including Luther and Calvin, held that Sunday did not replace the Jewish sabbath. But the Puritans, with their desire to regulate life by the Bible, and in the absence of any clear commands in the New Testament about Sunday observance by Christians, applied the Old Testament sabbath regulations to Sunday. A book by the English rector Nicholas Bownde (Bound), *The Doctrine of the Sabbath* (1595), which identified Sunday with the sabbath, was of great influence in this connection. In 17th-century England and Scotland, and hence also in parts of colonial North America, laws were passed forbidding public entertainments, sports, buying and selling and traveling on Sunday, in addition to the time-honoured prohibition on unnecessary work. Together with this went the strict practice in private life of confining the day to godly pursuits alone, alongside church worship. Restriction of public activities continued to be the subject of legislation, to facilitate opportunities for worship and keep the day holy. (See SABBATARIANISM)

In the changed conditions of the 20th century, however, Sunday legislation has often been relaxed. Yet Sunday generally remains a day of legal cessation of many forms of labour, and for Christians a day primarily of worship.

Rorert, *Der Sonntag . . . im ältesten Christentum* (1962).

**SUNDBYBERG**, a town of Sweden in Stockholm län (county), on the northwestern outskirts of Stockholm. Pop. (1960) 26,987. Founded in 1877 as one of Stockholm's first residential suburbs, it received its charter in 1927 and has become an important industrial centre. The church (1909-11), beautifully situated in a park, has some notable stained glass. Among other imposing buildings are those of the large Marabou chocolate factory, while around Storskogen Park is a district of modern multi-story apartment blocks. Electrical and chemical equipment, building materials, outboard motors, and other products are manu-

factured. Immediately to the southwest is Bromma Airport for internal services.

**SUNDERLAND, CHARLES SPENCER, 3RD EARL OF** (c. 1674–1722), English statesman, first lord of the treasury from 1718 to 1721, originated the financial schemes that resulted in the South Sea Bubble (*q.v.*). The second son of Robert, 2nd earl of Sunderland (*q.v.*), he succeeded to the earldom in 1702. When Spencer's first wife, Arabella, died in 1698, Sidney Godolphin (*see* GODOLPHIN, SIDNEY GODOLPHIN, Earl of), the reigning exponent of court politics, arranged a match for him with Lady Anne Churchill, second daughter of Godolphin's ally the earl (later duke) of Marlborough. The marriage was celebrated in 1700. Sunderland, however, devoted his skill in intrigue to the Whig Junto, and his marriage in the long run drew Marlborough and Godolphin toward the Whigs. In 1706 the Junto, as the price of their support, forced Sunderland upon Godolphin's ministry as secretary of state for the southern department. Sunderland's ungovernable extremism, and his violent support of the impeachment of Henry Sacheverell in 1710, were met by the rooted antipathy of Queen Anne, and his dismissal in June 1710 heralded the overthrow of the Whig government.

Sunderland conducted factious negotiations with the Hanoverian court, but on the accession of George I in 1714 he was bitterly disappointed by his relegation as lord lieutenant of Ireland. Currying favour with the king's mistress the baroness von Schulenburg (later duchess of Kendal) and with his German ministers, he became lord privy seal in 1715 and in 1716 went to the king in Hanover to foment the misunderstandings between the king and some London ministers over the delay in the conclusion of the Triple Alliance between Great Britain, France, and Holland. Sunderland succeeded in ousting Robert Walpole and Charles Townshend from office and established a new ministry in which as northern secretary (1717), lord president of the council (1718), and first lord of the treasury (1718) he shared chief influence with James Stanhope (created Earl Stanhope in 1718). Sunderland's plan to maintain a permanent majority in the Lords by his Peerage Bill (1719) and his South Sea scheme (1720) both failed disastrously (*see* ENGLISH HISTORY). Stanhope died in February 1721, and in April Sunderland had to yield office to Walpole and accept his protection from political attack. Sunderland died unexpectedly in London on April 19, 1722. (W. R. Wd.)

**SUNDERLAND, ROBERT SPENCER, 2ND EARL OF** (1641–1702), English statesman who held high office under Charles II and James II and who was one of William III's closest advisers, was the son of Henry, 3rd Lord Spencer (afterward earl of Sunderland), and Dorothy Sidney, daughter of Robert, 2nd earl of Leicester. He was born in Paris on Sept. 5, 1641, and succeeded to his father's titles on the latter's death at the Battle of Newbury in September 1643. He was ambassador to Madrid (1671–72) and to Paris (1672–73). He was sent to Paris again, as an envoy extraordinary, in July 1678, but he returned to London in October at the beginning of the crisis caused by the move to exclude James, duke of York (later James II), from succeeding Charles II. Sunderland was appointed secretary of state in February 1679.

His policies were not at first incompatible with his loyalty to his old patron the duke of York. With his uncle Henry Sidney (later earl of Romney) and his friends Sir William Temple and Arthur Capel, earl of Essex, he was soon identified with the group that supported Princess Mary (later Mary II) and her husband William of Orange (later William III) and rejected the claims of James, duke of Monmouth, to the succession. By 1680 he had emerged as one of the chief ministers of Charles. On the assembly (October 1680) of the Parliament that brought in the second exclusion bill, he decided that the duke of York must be sacrificed to prevent the complete triumph of Monmouth and the Whig opposition, and, although he could not convert the king to his views, he voted for the exclusion bill (November 1680). For this he was dismissed from his offices in disgrace in January 1681, but his abilities as an administrator and his knowledge of foreign affairs were such that he could not be permanently discarded, and the following year, aided by the influence of the king's mistress, Louise

de Kéroualle, duchess of Portsmouth, he was reconciled with the king and the duke of York and returned to court in July 1682. He was reappointed secretary of state in January 1683.

From 1683 until the Revolution in 1688 Sunderland was associated with the authoritarian, pro-French, pro-Catholic policy that was a feature of this period. In December 1685, soon after James II's accession, he was appointed lord president of the council, and the dismissal of his chief rival and political opponent, Lawrence Hyde, earl of Rochester, in January 1687, left him as the chief minister. There is some evidence to show that he tried to moderate James's more extreme policies, but his own position at court was never strong enough for him to make a stand, even if his rather attenuated moral principles had dictated it. In June 1688 he felt obliged to turn Roman Catholic. On the other hand, there is no evidence to support the legend that he betrayed James by offering his support to William of Orange, and the probabilities are against it; though William always retained a high regard for him, which was manifested after the Revolution.

Dismissed in October 1688, Sunderland fled to Holland in December and was exempted from both James II's and William III's proclamations of pardon. He returned to England in May 1690, having abandoned the Roman faith, and in two years established himself as one of William's most valued political advisers and the principal intermediary between him and the parliamentary leaders. It was mainly his pressure that obliged William to form a new war ministry round the Junto Whigs in 1693. But the loathing with which the public, and many practising politicians, regarded him reached its peak in April 1697, when he made the mistake of accepting William's pressing offer of the lord chamberlainship. The hostile reaction of the House of Commons drove him to resign in December, and the king did not easily forgive his "desertion"; however, William was happy to consult him on the formation of a new ministry in 1700 and again in 1701. Sunderland did not long survive the king, dying at Althorp, Northamptonshire, on Sept. 28, 1702.

He married Anne Digby, daughter of George, 2nd earl of Bristol, in 1665. Their only surviving son, Charles, 3rd earl, married Anne Churchill, second daughter of the great duke of Marlborough, and their grandson Charles, 5th earl of Sunderland, succeeded as the 3rd duke of Marlborough in 1733. From him is descended the Spencer Churchill family.

*See* J. P. Kenyon, *Robert Spencer, Earl of Sunderland 1641–1702* (1958). (J. P. K.)

**SUNDERLAND**, a seaport, municipal, county and parliamentary borough situated at the mouth of the Wear river in County Durham, Eng., 13 mi. (21 km.) NE of Durham by road. Pop. (1961) 189,686. Area 13.4 sq.mi. (34.7 sq.km.). It is a great shipbuilding centre (shipbuilding was recorded as early as 1346) and has also big ship-repairing and marine-engineering works. Coal was first shipped from the port in 1396 and the tonnage exported per year from Wearmouth and other collieries had reached 5,000,000 before World War II. There are several foundries and the largest ships' anchors are made there. Other manufactures include telecommunication equipment, ropes, aircraft engineering, furniture, clothing, confectionery, pottery (the Sunderland lustreware was an early product), glass, beer and many more.

The Wear river commissioners administer the port of Sunderland which has a well-equipped deep-water quay and several wet and dry docks. The two curved piers at the entrance, on one of which stands a lighthouse, enclose about 130 ac. In addition to coal and coke Sunderland exports iron and steel, machinery, paper, coal tar, pitch, glassware, etc. The main imports are timber, grain, sisal and hemp, esparto, iron ore, wood pulp, fuel oil and petroleum. Within the borough are the seaside resorts of Roker and Seaburn, with fine sands.

In Sunderland there are a technical college, affiliated to Durham university and specializing in electrical engineering and other subjects, a teachers' residential training college and a college of art. There is a museum and art gallery.

**History.**—In 674 a monastery was established on the north side of the river by St. Benedict Biscop and a church built, dedicated to St. Peter. The church is still in use and retains parts of the

original building. The Venerable Bede was born at Wearmouth about 673 and studied at the monastery. Biscop brought over skilled Frankish workmen who made glass for the windows of the church—the first recorded instance of glassmaking in England.

The area in which the monastery was located became known as Monkwearmouth. Sunderland was the part "sundered" from the monastery by the river. Bishopwearmouth, immediately west of Sunderland, had been granted in 930 to the bishops of Durham, by Aethelstan. In 1382 there was probably a dock there and from the 16th century Bishopwearmouth seems to have been completely identified with Sunderland. In 1567 Wearmouth was one of the three ports in Durham where precautions were to be taken against pirates, while no mention is made of Sunderland. Monkwearmouth remained purely agricultural until 1775, when a shipbuilding yard was established and prospered to such an extent that by 1795 five similar yards were at work. Prosperity continued until the depression of the 1930s caused severe unemployment—41% of the insured population in 1934.

From the 9th to the 11th century the district suffered from successive raids from the Danes and the Scots. Hugh Pudsey, bishop of Durham, granted a charter toward the end of the 12th century, elevating Sunderland to borough status. In 1634 Bishop Thomas Morton granted a further charter. During the Great Rebellion Sunderland supported the parliamentary cause. Newcastle took the royalist side and an embargo on ships leaving the Tyne resulted in increased shipments from the Wear. In 1717 a board of harbour commissioners was appointed to develop the port.

In 1796 the river was spanned by what was then the longest single-span cast-iron bridge in the world (an aluminum alloy bridge opened in 1948 also created a record). Sunderland was incorporated in 1634 and became a parliamentary borough in 1832. It returns two members to parliament.

**SUNDEW**, an insectivorous plant of the genus *Drosera*, of which there are more than 90 species with worldwide distribution. There are four species in North America and three in Europe. The most extraordinary development of this genus is attained in Australia and south Africa, where, in addition to the low, soft, herbaceous plants found elsewhere, occur tall plants attaining a height of three feet, with wiry stems that climb by the aid of adhesive leaf blades.

All species are carnivorous. They catch their prey by means of tentacles that spring in a regular pattern from the upper surface of the leaf blade. As many as 400 tentacles have been counted on a leaf of *D. rotundifolia* 0.9 cm. in diameter. The tentacles vary in size, shorter in the middle of the blade and much longer (0.6 cm.) along and near the margins. In some species with linear leaves there is little or no difference in size. Each tentacle consists of a stalk, broader at the base and tapering to the top, which supports an oval or rounded gland of rather complex structure. The middle of this gland is occupied by a cylindrical mass of water vessels enclosed within a bell-shaped layer of flat cells. The cells that form the edge of the bell extend to the outer surface of the gland. Covering this bell are two courses of cells normally filled with red or purplish sap. Each gland secretes and supports a droplet of mucilage, which accounts for the dewy appearance of the leaf. The red point of colour shining through the clear mucilage presents an appearance of rare beauty, which appears to attract insects. Connecting the gland with the vascular tissues of the leaf is a strand of vascular tissue extending through the stalk and base to the veins of the blade.

The tentacles are capable of motion. Darwin was the first to make extensive experimental studies on the matter. When a small insect alights on the leaf, its escape is prevented by the mucilage, which smears and smothers it during its struggles to escape. The presence of an insect provides a stimulus to neighbouring tentacles, which bend toward the prey and attach themselves to it by their mucilage, bringing a large contact surface to bear. A digestive ferment is secreted that attacks the nitrogenous content of the prey. The products of this digestion are then absorbed by the same glands. The movements of the tentacles are complex, but the net result is to bring the body of the prey toward the middle zone of the leaf blade, which itself can bend to surround the prey.

There are also many minute sessile glands, scattered over both leaf surfaces, whose function is problematical. The leaf blade may be nearly orbicular, or linear and rushlike (it is then nonmotile with various intermediate forms. Some are peltate (i.e., having the stalk attached to the underside rather than to the base of the leaf) and circular, bowl shaped, or lunate, others variously ovate to large strap shaped.

Reproduction takes place not only by seeds but also by leaf buds which spring normally from the bases of the tentacles, more abundantly on leaves that have been detached. In one or two species buds, in the form of gemmae, spring from the apex of the stem after the foliage leaves have been produced. Some species produce "droppers," special branches with negative geotropism, which penetrate the substrate. Their ends then enlarge into tubers. Closely related to *Drosera* are the genera *Drosophyllum* and *Byblis*, both carnivorous, and *Roridula*, which traps insects but does not utilize them as food.

**SUNDIAL**, a device which indicates divisions of the day by the motion of the shadow of some object on which the sun's rays fall. It is one of the earliest examples of the application of man's knowledge of the apparent motion of the sun across the sky, and is constructed in various ways.

**History.**—The first device used was probably the gnomon. This consisted of a vertical stick or pillar, and the length of the shadow which it cast gave an indication of the time of day. By the 8th century B.C. it is clear that more precise devices were in use, and the earliest known sundial still preserved is an Egyptian shadow-clock of green schist dating at least from this period. This clock consists of a straight base and a crosspiece set at 90° to it. The base was placed in an east-west direction and the shadow of the crosspiece fell across the base, upon which was inscribed a scale of six time divisions. Clocks of this kind are still in use in primitive parts of Egypt; they are positioned so that the crosspiece lies to the east before noon and to the west after noon.

Another early device was the hemispherical sundial or hemicycle. It is attributed to the Babylonian astronomer Berosus (Berosus, fl. c. 300 B.C.). Made of stone or wood, the instrument consisted of a cubical block into which was cut a hemispherical opening; to this was fixed a pointer or style, the end of the style lying at the centre of the hemispherical space. The path traced by the shadow of the style was, approximately, a circular arc. The length and position of the arc varied according to the seasons, so an appropriate number of arcs was inscribed on the internal surface of the hemisphere.

Each arc was divided into 12 equal divisions and each day reckoned from sunrise to sunset, had therefore 12 equal intervals or hours. Because the length of the day varied according to the season, these hours likewise varied in length from season to season and even from day to day, and were consequently known as temporary hours. The dial of Berosus was widely used for many centuries, and, according to the Arab astronomer al-Battani (Albategnius, c. A.D. 858–929), was still in use in Muslim countries during the 10th century.

The Greeks, with their geometrical prowess, developed and constructed sundials of considerable complexity. Apollonius of Perga (c. 250 B.C.) developed the hemicycle by using a surface of conic section upon which the hour lines were inscribed; this arrangement gave greater accuracy. Ptolemy used the analemma, a device which enabled shadows to be projected geometrically on vertical flat surfaces inclined at various angles to the horizontal. In general it appears that the Greeks constructed instruments with either vertical, horizontal or inclined dials, indicating time by temporary hours. The Tower of the Winds in Athens, which is octagonal in shape and dates from about 100 B.C., contains eight sundials. It is therefore clear that dials facing various cardinal points were in use for a long time.

The Romans also used sundials with temporary hours. The first dial set up in Rome in 290 B.C. had been captured from the Samnites, but it was not until almost 164 B.C. that a sundial was

actually constructed for the city. In his great work *De Architectura*, M. Vitruvius (1st century B.C.) mentions many types of sundials, including portable ones.

The Arabs attached much importance to the study of sundials, the principle and design of which they derived from the Greeks. They increased the variety of designs available and, at the same time, simplified the processes of design and construction by using the principles of trigonometry. Abu'l Hasan, at the beginning of the 13th century A.D., wrote on the construction of hour lines on cylindrical, conical and other surfaces and is credited also with introducing equal hours, at least for astronomical purposes. With the advent of mechanical clocks in the early 14th century sundials with equal hours gradually came into general use.

During the Renaissance the construction of sundials flourished; there was a great diversity of forms, and some dials of considerable artistic merit were produced. The making of sundials was a profitable business and required not only considerable manual skill but also some understanding of the theoretical principles of the apparent motion of the sun; in consequence, the methods of sundial design and construction were jealously guarded trade secrets. From the 16th century onward, however, the growing spirit of inquiry into natural phenomena caused this secrecy to give way to open discussion, and in Basel in 1531 the German cosmographer Sebastian Münster (1489–1552) published his *Compositio Horologiorum*, which contained details of sundials and also of a moondial.

By the 17th century the study of dialing, as it was then called, formed a branch of education. The German Jesuit astronomer Christopher Clavius (1537–1612) published in 1581 the *Gnomonices*, in which he virtually summed up all knowledge on dialing at that time. Universal sundials, adjustable for use in any latitude, were a feature of the 18th century, although such instruments had been constructed earlier.

The increasing accuracy of clocks and watches eventually made the sundial obsolete. By the 19th century sundials were, in general, used only as ornaments in gardens, although it is to be noted that certain instruments of a very precise kind, such as the heliochronometer, were designed and used for scientific purposes.

**General Principles.**—Time-keeping by sundial depends on the changing position of the sun in the sky. As is well known, this apparent motion is caused by the diurnal rotation of the earth and by the motion of the earth in an elliptical orbit about the sun. The diurnal motion causes the sun to appear to rise in the east and to set in the west. The orbital motion gives rise to three other factors which the designer of a sundial has to take into account if correct time indications are to be obtained. The first of these is due to the earth's motion about the sun as a focus; because of this the apparent motion of the sun is retarded, so that it takes four minutes longer to move across the sky than do the stars.

The second factor is due to the elliptical nature of the earth's orbit. This causes the earth to move more slowly when far from the sun than when near to it, so the velocity of the sun's apparent motion varies according to the time of year. Third, the inclination of the axis of diurnal rotation is inclined by  $23^\circ$  to the plane of the earth's orbit; therefore in summer the apparent path of the sun (the ecliptic) is higher in the sky than in winter and the duration of sunlight is longer. There is also the latitude of the observer to be considered; this affects the maximum height which the sun reaches above the horizon, and thus the inclination of the style or the position of the hour lines on a sundial.

Although it was not until the 17th century that the earth's orbit was correctly understood, sundials of considerable accuracy could nevertheless be constructed because dialing is concerned with the apparent motion of the sun. Temporary hours were sufficient until the advent of mechanical clocks, when reckoning of time in equal hours became necessary. Such equal hours give a mean solar time compared with the apparent solar time of temporary hours.

Mean solar time is based upon the behaviour of a fictitious body called the mean sun, which is assumed to travel along the celestial equator at a uniform speed. The mean sun coincides with the true sun at the equinoxes and solstices. The time difference between the two is known as the equation of time and is defined as mean solar time minus true solar time. The greatest numerical value of the equation of time, of the order of 16 minutes, occurs at a point between each equinox and solstice.

For indicating true solar time a sundial is oriented so that the style lies in the meridian and, in the cases of vertical, horizontal and inclined dials, with the style parallel to the earth's polar axis, i.e., inclined to the horizontal by an angle equal to the latitude of the place at which the dial is to be used. At local noon as indicated by the true sun, the shadow cast by the style should fall on the noon mark engraved on the appropriate hour line. A sundial may be oriented by a compass or, if a compass is not available, by a plumb line to the end of the style. The shadows cast by the style employing a plumb line should coincide over the noon mark at the aid of Local noon as indicated by the true sun may be obtained of similar time and making due allowance for the upper coinage by the printing being set up.

Sundials for use in the southern hemisphere are used in the northern, except that the hour lines are in opposite direction. The noon mark and orientation entered the in a similar manner.

**Types of Sundial.**—*T-Shaped Dials.*—The use of in Egypt in very ancient times. They usually consisted of a simple inscribed bar with a perpendicular block with two sloping sides cut in steps of rectangular block at each end. In the national university at the duty for hour lines and the instrument was trained for governmental at midday.

*Hemispherical Dials.*—In the original T'ang period had been hemispherical depression was cut in the families of north China. only part of the hemisphere was used. Educational positions encouraged situated at one end of the block to nations. Candidates were sub-noted, Apollonius of Perga used through written tests on three which gave greater accuracy. Training the ordeal for each one who the late 16th century in Italy, numbers thus recruited rose from a of a cup or goblet. There were over 200. The effort to devise were inscribed on the interior.

*Sunken Dials.*—In fashion and testing methods. To preserve this kind were usually made to bidate and ensure fairness in grading, variation of the hemisphere copied by clerks, examinees were identified a great variety of forms. Three examiners read each paper. Higher triangular and heart-shaped to nominate junior relatives for admission became popular to cut, the great stress on examination grades in of churches and into the practice of recruiting many lower officials.

*Cubical Dials.*—The clerical service ensured a considerable free-these sundials had. Promotion of the more able and reliable was Different time scales, fully guaranteed recommendation by higher of a well-preserved, equal merit ratings.

FLORENTINE CUBICAL SUNDIAL  
SHOWING ITALIAN HOURS, c. 1560

The bureaucracy was successful in drawing into its ranks nearly all of the ablest educated men. As a result, the outstanding achievements in fields of the greatest diversity were by men active in government and politics. The "universal man" was the typical figure of the time. A leading official might be creatively concerned with philosophy, history writing, poetry, science or painting, and most often with several of these: Ou-yang Hsiu, Fan Chung-yen, Su-ma Kuang, Wang An-shih, Shen Kua, Su Tung-p'o, Chu Hsi, Lu Hsiang-shan and Wen T'ien-hsiang were but a few of the most famous. Women were represented by such examples as the poet-archaeologist Li Ch'ing-chao. The emperor Hui Tsung—painter of the first rank, calligrapher, patron of art and archaeology—was the best-known instance of such versatility among the Sung emperors, but not the only one.

**Political History of the Dynasty.**—The character of officialdom and the tradition of the ruling house created an atmosphere favourable to spirited political debate. After the vigorous rule of Chao K'uang-yin (960-976), who took the reign title of T'ai Tsu, and his brother T'ai Tsung (976-997), both circumstances and the rulers' personalities tended to confine their role to that of selecting the chief officials and resolving divergences over policy. The emperor Chen Tsung (997-1022) was unsettled in mind during his later years; on the accession of the 11-year-old Jen Tsung (1022-63) the empress dowager ruled as regent; his successor, Ying Tsung (1063-67), was an invalid during his short reign. The authority deputed to the councilors of state was tempered by the influences of the censorate, the bureau of policy criticism and the bureau of academicians, and discussions at court on questions of policy often ranged officials of these and other bureaux in opposing groups. While more ardent followers of Confucius were never satisfied that his precepts of government through moral principle, character and reason were fully applied, the early Sung perhaps came closer than any other period to realizing the Confucian political ideal in practice.

But factional divisions grew acrid as economic and military problems became pressing. Rising farm population and equal land inheritance aggravated the burden of heavy taxes for the small farmer, who often lost his lands to larger landholders who could keep their lands in better condition and farm them more effectively. While the government depended increasingly on state monopolies or excises—salt, metals, wine, alum, aromatics and foreign imports—the total state income had begun to decline. Fan Chung-yen and others had proposed and sometimes implemented schemes to deal with some of these problems, but the difficulties increased. Wang An-shih (*q.v.*) offered a more radical and comprehensive program to deal with the mounting difficulties. He advocated increased economic planning by the government and urged that the training of government officials be made more practical and technical. Firm support by the emperor Shen Tsung (1067-85) enabled Wang to carry out his program despite the antagonism of his leading contemporaries, which he invited by impatiently ousting from office all who questioned the prudence of any new measure. The magnitude of the problem and the bureaucrats' ineptness in applying the new laws limited their success. They were repealed under the regency of the empress dowager Hsuan-ho early in the reign of Che Tsung (1085-1100) and restored when the emperor assumed personal power. Despite the moderating efforts of the following ruler, Hui Tsung (*q.v.*; 1100-25), the struggle of the pro-Wang and anti-Wang factions continued for several generations, during which one or the other party was sometimes declared anathema and barred from all official rank or function.

In the meanwhile the military situation had further deteriorated. After the initial achievement of recovering from the Khitan (Liao) empire all that it had seized of north China excepting a small strip within the Great Wall, and the subjection of the independent principalities in south China, the rulers curtailed the powers of their commanders to forestall a recurrence of the war lordism that had destroyed the T'ang. The peace of the 11th century was unbroken until midway in Jen Tsung's reign when the new Tangut (Hsi-hsia) empire invaded the northwest frontier, and the Khitans in the north were kept neutral only through appeasement payments. The regular troops were softened by ease, and the enemy was

repelled only by the raising of militia corps. Wang An-shih included in his program a provision for regular militia reserves and for army horses to be kept by farmers. The inadequacy of the army was shown when the Jurchen (Chin) empire, after overthrowing the Khitan in alliance with the Sung, invaded China and attacked K'ai-feng. After a humiliating peace and the abdication of Hui Tsung to his son Ch'in Tsung (1125-27), the Jurchen renewed the fight, took both emperors captive and invaded the Yangtze valley. Under Kao Tsung (1127-62), who established the capital of the Sung at Hangchow, the Chinese responded to the emergency. Led by Yueh Fei and other generals they threw the invaders back. Perhaps for economic reasons, the councilor Ch'in Kuei nevertheless determinedly renounced the reconquest of the north, made peace with the Jurchen in 1141 and executed the recalcitrant Yueh Fei who was revered thereafter as China's national hero. Despite the fervid national spirit that could be aroused in times of crisis, the Chinese of the Sung had grown less martial and depended increasingly for military success on the technical development of weapons. Incendiary projectiles had long been used; explosive grenades appeared by the 13th century and by the end of the dynasty it appears that cannons were also employed. Such weapons also armed the large navy that was built up in the Southern Sung.

With such help the Sung Chinese enjoyed another century of relative prosperity and intellectual flowering, despite accumulating difficulties with monetary inflation and an unsolved farm problem. Under the reigns of Hsiao Tsung (1162-89), Kuang Tsung (1189-94) and Ning Tsung (1194-1224). But China's security was precarious. The Jurchen, and then the Mongols who conquered them, in time discovered the secrets of China's new weapons, and technicians from occupied north China could copy them. Chinese technical skill was forced to surpass itself in creating still newer weapons to counter the earlier ones. Beginning in the second decade of the reign of Li Tsung (1224-65) and continuing through that of Tu Tsung (1265-74), the key fortresses guarding the northern approach by the Han river fell after a prolonged siege, and during the brief reigns of Kung Tsung (1274-76) and the child emperors Tuan Tsung (1276-78) and Ti-ping (1278-79) the Sung court sought successive refuges near the Canton estuary while Wen T'ien-hsiang and other loyal leaders fought defensive actions; it was believed that after a last unsuccessful naval engagement the Sung admiral perished in the sea with the infant ruler rather than surrender him to the Mongols.

**Intellectual and Artistic Achievements.**—In its cultural life the Sung dynasty was a time of beginning in some respects and of culmination in others. The rise of cities, new wealth and wider availability of education called into being new forms of entertainment to please simpler tastes and led a larger number to pursue more sophisticated forms of intellectual satisfaction. To the amusements of acrobatic troupes and displays of fireworks were added simple theatrical presentations that were to develop into the drama of later dynasties and itinerant storytellers whose prompting books held the plots of later historical and picaresque novels. The forms of verse developed by the great T'ang poets were employed subtly and elegantly as the habitual expression of educated men, reaching greatness at the hand of Su Tung-p'o and a new form of poetry was brought to perfection—the writing of lyrics to well-known melodies. Great skill was devoted to art-craftsmanship, and the manufacture of porcelain, while it did not reach the technical dexterity of the Ming and Manchu periods, attained perhaps its highest aesthetic perfection. Buddhist sculpture found its fullest grace; landscape painting, at the brushes of masters like Kuo Hsi, Hsia Kuei and Liang K'ai, attained successive heights of expressiveness, subtle mood and mysticism that were scarcely to be touched again.

While Buddhism had passed its intellectual prime in China, its past attainments challenged reviving Confucianism to create a metaphysical system that could answer the problems the Buddhists had raised. Freedom of speculation prevailed, and private academies taught a diversity of interpretations; the two most influential formulations were those reached in the 12th century by Chu Hsi (*q.v.*), whose discipline stressed the extension of knowledge

and the more mystical Lu Hsiang-shan. While the system of Chu would become orthodox in later times, that of Lu was the forerunner of Wang Yang-ming's heterodoxy. The explanation of nature concerned systematic thinkers like Chu Hsi, and men like Shen Kua combined active interests in mathematics, theoretical speculation and the many advances that Chinese were making in practical technology, ranging from new medical practices to the development of the mariner's compass.

Ssu-ma Kuang and Li Tao typify the many historians who applied more critical methods, created new forms of historiography to present the causation and relationship of events and treated recent history in works impressive for size and detail. The thought of the time is expressed also in the popularity of the essay; and the individual personalities of the period are well preserved in the many collections of letters and other smaller pieces that were first published in large numbers.

**SUNN** (SANN, SUNN HEMP, or INDIAN HEMP) embraces at least two species of *Crotalaria*, of the pea family (Leguminosae). *Crotalaria juncea* is best known as the source of an inner bark or bast fibre, which also is termed sunn. Sunn is a familiar plant in Asia, and has been naturalized in the West Indies. Other species of *Crotalaria* are employed as cover crops in the southern United States. Sunn fibre of commerce comes almost entirely from India, where *C. juncea* is grown and marketed much as is jute. The fibre is of better quality than jute, approaching hemp or flax in its characteristics. Thousands of tons are produced annually, much of it locally consumed for coarse cloth, cordage, sacking, and calking. Sunn fibre imported into the U.S. has usually been employed in the making of special papers, such as that for cigarettes.

The plants are low shrubs with slender silky stems, undivided leaves, and bright yellow flowers. At maturity seeds rattle loose in the pealike pod, giving rise to the name *Crotalaria*, from the Greek word for "rattle," source also for *Crotalus*, the rattlesnake. The fibres develop as bundles or strands in the inner bark next to the woody core of the stem, and are usually freed from the softer surrounding tissues by the process known as retting. Retting depends upon bacterial decomposition or "rotting" of the thin-walled weaker cells, and is completed in four or five days with sunn. The thick-walled resistant fibres can then be sloughed free of decomposing debris and core. The four- or five-foot-long fibre strands are dried and marketed as yellowish or grayish hands.

Sunn fibres are essentially pure cellulose. Were they to contain any aromatic principles, certain to be evident as "off flavours" upon burning, sunn could not substitute for flax in the making of cigarette paper. (R. W. SV.)

**SUNNISM**, the main body of Islam, referring to the followers of the Way (*sunna*) of the Prophet. The term *ahl al-sunna wa l-jama'a*, "the people of the *sunna* and of the community," describes the orthodox, generally meaning as opposed to the Shi'ites (see SHI'ISM). See ISLAM.

**SUNNYVALE**, a city of Santa Clara County in northern California, U.S., 39 mi. S of San Francisco, is noted primarily for its two major industries, electronics and guided missiles. Incorporated in 1912, the city adopted the council-manager form of government in 1949. Originally a part of the Mariano Castro land grant, it was known as Murphy's Station from 1850 to the turn of the century and then briefly as Encinal; the name Sunnyvale was officially adopted in 1912. Between World Wars I and II it was chiefly a cannery centre processing the fruit of the extensive orchards nearby. Industry came to the area during World War II and the Korean War; its population rose from 4,373 in 1940 to 52,898 in 1960. For comparative population figures see table in CALIFORNIA: Population. (J. J. HA.)

**SUNSHINE**, the sun's light; the direct rays neither scattered nor reflected; hence the warmth and light given by the sun's rays. Sunshine includes not only the visible portion of radiation from the sun, but also invisible ultraviolet and infrared rays (see also SUN). Radiation from the sun is the ultimate source of nearly all energy that is essential for the maintenance of plant and animal life on the earth and the operation of most natural phenomena on the surface of the earth. In particular, the amount and distribution in time and space of the solar radiation which is intercepted by the earth are the prime cause of weather and climate. (For man's attempts to harness the energy of the sun, see SOLAR ENERGY, UTILIZATION OF.)

The energy output of the sun has its peak at  $0.47\mu$  ( $0.00047$  mm.) and radiates 8 kw. per square centimetre into space. At the earth's surface the amount received is on an average 1 kw. per square metre. The energy measured at the outer boundary of the atmosphere, the so-called solar constant, is 2 cal. per square centimetre per minute on a surface normal to the rays at the mean distance between sun and earth. The amount of possible sunshine for each point on the earth's surface is determined by latitude and season, as shown in Table I.

TABLE I.—Possible Duration of Sunshine in Various Northern Latitudes (Hours:Minutes)

Date	10°	30°	50°	70°	90°
Feb. 15	11:49	11:10	10:07	7:20	0:00
April 15	12:21	12:53	13:44	16:06	24:00
June 15	12:42	14:04	16:21	24:00	24:00
Aug. 15	12:28	13:16	14:33	18:26	24:00
Oct. 15	11:55	11:28	10:47	9:03	0:00
Dec. 15	11:32	10:14	8:05	0:00	0:00
Longest day	12:35	13:56	16:09	24:00	24:00
Shortest day	11:25	10:04	7:51	0:00	0:00

**Duration.**—At the surface of the earth cloudiness is the primary factor governing the amount of sunshine actually received, but even through dense clouds or fog some diffuse radiation still penetrates. The insolation received through various cloud types (in percent of clear sky radiation) is: cirrus 83%, cirrostratus 78%, altocumulus 49%, altostratus 41%, stratocumulus 32%, stratus 25%, nimbostratus 20%, fog 18%.

The distribution of sunshine over the earth varies from over 4,000 hours per year; i.e., more than 90% of the possible, to less than 2,000 hours in the storm belts. The Sahara Desert gets the largest amount, areas around Iceland and Scotland are among those getting least.

In the conterminous United States, Arizona shows the greatest amounts of sunshine, the Pacific northwest coast receives least. The variation throughout the year in terms of the possible duration in various parts of the world is given for a selection of representative stations in Table II.

The sunshine shows in most places a rather regular variation throughout the day. A common situation, representative of many parts of the U.S. and other moderate latitudes, is cloudiness in early morning, fewer clouds in late morning and early afternoon, and an increase in cloudiness again in late afternoon.

**Quality.**—The major portion of sunshine which penetrates through the atmosphere ranges in wave length from  $0.29\mu$  to  $2.5\mu$ . Ordinarily, sunshine is broken down into three major components: (1) the visible, or that part between  $0.4\mu$  and  $0.8\mu$  (one octave of wavelength); (2) the ultraviolet, or that portion with wavelengths shorter than  $0.4\mu$ ; and (3) the infrared with wavelengths longer than  $0.8\mu$ .

Because of a continual shift in the position of the maximum of the solar energy curve, no one factor can be used accurately to convert values in gram calories to values in footcandles. However, the value of 6,500 footcandles per gram calorie suffices for most practical purposes.

**Visible Radiation.**—Visible radiation is commonly termed light; however, the word light now has a broader meaning and includes the ultraviolet, or that invisible portion immediately adjoining the shortest wavelength of visible radiation. The visible portion comprises nearly one-half of the total radiation received at the surface of the earth.

\*In percent of possible.

**Ultraviolet Radiation.**—While ultraviolet light comprises only a very small proportion of the total radiation, this component is extremely important. It produces vitamin D through the activation of ergosterol. It also is an important germicidal agent. Unfortunately, the contaminated atmosphere over large cities robs radiation of practically all the shorter wavelengths.

Ultraviolet and the near ultraviolet rays comprise the so-called actinic rays which are very potent in effecting chemical changes on photographic films.

**Infrared Radiation** has its chief merit in its heat-producing quality. Close to one-half of total solar radiation received at the surface of the earth is infrared. The spectrophotometer is the most important instrument for measuring small components of sunlight. Solar rays of different wavelengths are refracted on entering and emerging from a prism, the shorter wavelengths being refracted more than the infrared rays. It was through the use of the spectroscope and matched absorption bands that knowledge of the composition of the sun was determined.

The sunshine reaching the outer edge of the earth's atmosphere is closely equivalent to the radiation of a black body at a temperature of 5,800° to 6,000° C. On its path through the atmosphere this radiation is absorbed and weakened by various constituents of the atmosphere. It is also scattered by air molecules. This scattering, which occurs in the shorter wavelengths, causes the light-blue colour of the sky at the earth's surface. In the stratosphere, with fewer air molecules above the observer, the sky appears dark.

An effective absorber of solar radiation is ozone, which forms by a photochemical process at heights of 20 mi. and filters out most of the radiation below 0.3 $\mu$ . Equally important as an absorber in the longer wavelengths is water vapour. A secondary absorber in the infrared range is carbon dioxide. These two filter out much of the solar energy below 1 $\mu$ .

In the low layers of the atmosphere, dust scatters and absorbs effectively. At sunrise and sunset sunlight has a long path through the turbid air. The light is much attenuated and the short wavelengths are scattered. This causes the red colour of the sun at those times and permits one to look directly into the sun.

**Measurement of Sunshine.**—Several devices are used to record sunshine.

**The Campbell-Stokes Sunshine Recorder.**—This instrument consists essentially of a segment of a spherical metal bowl, having a glass sphere placed concentrically within it and centred so that the sun's rays are focused on a card lining the bowl. Direct sunshine burns a spot or a line on the card. Differentiation between a record of a few seconds and a minute of intense sunlight is difficult because the two traces are similar. Also, when the sun is barely visible through smoke or thin clouds, its rays are too weak

to make a record.

Modified forms of sunshine recorders use blueprint paper mounted on a cylinder. The Jordan type contains two semi-cylinders with narrow slits in their narrow sides and, like the Campbell-Stokes recorder, maintains its own time record.

**The Marvin Sunshine Recorder.**—This is an air thermometer in which an electrical circuit is closed through the expansion of mercury by thermal action of the sun.

The instruments so far mentioned merely indicate when the sun shines.

**The Eppley Pyrheliometer.**—This unit accurately responds to nearly all the radiation which reaches the surface of the earth on a horizontal surface and gives

quantitative results. The instrument consists of two concentric rings of equal area, one blackened and the other white coated. The hot junctions of a multiple thermopile of gold-palladium and platinum-rhodium alloys are attached to the lower side of the black ring, and the cold junctions are fastened to the lower side of the white ring. The differential in temperature between the two rings when radiation falls upon them creates an electromotive force that is nearly proportional to the amount of radiation received. The rings are mounted horizontally in the centre of a thin spherical glass bulb which is sealed to prevent deterioration of the receiving surfaces and also to prevent moisture from condensing within. The electromotive force generated by the receiver is recorded on a potentiometer and reduced to values in gram calories per minute per square centimetre.

For information regarding the biological effects of the sun's radiation, see RADIATION: BIOLOGICAL EFFECTS: Radiation and Human Health: Effects of Hertzian Waves and Infrared Rays and Effects of Visible and Ultraviolet Light. See also METEOROLGY: Solar and Terrestrial Radiation; RADIATION BALANCE OF THE EARTH; and references under "Sunshine" in the Index.

(I. F. H.; H. E. Lc.)  
**SUNSTONE**, a variety of the mineral feldspar (q.v.) exhibiting a brilliant spangled appearance in certain directions, caused by minute scales of iron oxide arranged parallel to a cleavage. It is somewhat similar to aventurine. The best-known locality is in Tvedestrand, Nor. It is also found near Lake Baikal, Sib., and at several localities in the U.S., especially at Middletown, Pa., and Statesville, N.C.

See also AVENTURINE.

**SUNSTROKE:** see HEATSTROKE.

**SUN WORSHIP.** The sun, as the most prominent representative of the heavens, plays a central role in primitive man's life. It regulates the change between day and night and is a benevolent giver of warmth as well as the terrible sender of unsupportable heat. In the ancient high cultures, as well as among preliterate peoples, the sun was an object of worship.

**Ancient Egyptian Religion.**—In Egypt the sun-god Re (q.v.) was the dominating figure among the high gods and kept this position from the most remote times. However, the sun was worshiped also by other names—as Kheper in the symbol of the scarab and as Horakhte, "the Horus of the Horizon." In the myth relating the voyage of the sun-god over the heavenly ocean the sun sets out as the young god, Kheper; appears at noon in the zenith as the full-grown sun, Re; and arrives in the evening at the western region in the shape of the old sun-god, Atum. The right eye of the god, the Horus eye, as the "Sun-Eye," was the central figure of mythical speculation (see HORUS). When Ikhnaton reformed Egyptian religion, he took up the cult of the ancestor deity Re-Horakhte under the name of Aton, an older designation

of the sun's disk. The hymns of this age, the Amarna period, give insight into the deeper aspects of solar religion. Above all, the sun's qualities as creator and nourisher of the earth and its inhabitants are glorified. The great importance of the so-called Aton hymns is shown by their influence on Hebrew cult lyrics, as, for example, Psalm 104. (See further EGYPT: *History: Ancient Religion*.)

**Sumerian and Semitic Religion.**—The sun-god occupied a central position in both Sumerian and Akkadian religion, but neither the Sumerian Utu nor the Semitic Shamash (*q.v.*) was included among the three highest gods of the pantheon. In religious literature Shamash is above all a guardian of justice and punisher of evil. In the Epic of Gilgamesh he is the constant supporter of the hero. He sees everything and foretells the future, and for this reason the seers are attached to him. (See further BABYLONIA AND ASSYRIA: *Religion*.)

Shamash belongs to the oldest Semitic pantheon. As Shemesh he was worshiped among the western Semites, as is shown by many Palestinian place-names; and as the goddess Shapash, the same deity plays a certain role in the mythical epics found in the excavation of Ras Shamra (ancient Ugarit). The female character of the sun deity recurs also in Arabia, where Shams enjoyed a widespread worship. Traces of the male deity are found also in the Old Testament (Ps. 19:4-6).

**Indo-European Religion.**—The sun was one of the most popular deities of the Indo-European peoples and a symbol of divine power. Sūrya is glorified in the Vedic hymns of ancient India as the all-seeing god who observes both good and evil actions. He expels not only darkness but also evil dreams and diseases. His existence is attested as early as the Kassites of Mesopotamia, among whom Suriyash is found, as well as in the Mitanni kingdom of northern Mesopotamia, where the proper name Shuwardata, "Given by the Sun," occurs. The Indian Sūrya has a female consort, Sūryā, who is thought of sometimes as the daughter of Sūrya, and sometimes as the daughter of Savitar, apparently only an aspect of Sūrya. Sun heroes and sun kings also occupy a central position in Indian mythology, where Vivasvant, the father of Yama, corresponds to the Iranian Vivahvant, the father of Yima. There is a dynasty of sun kings, characterized by peaceful character, quite distinct from the warlike moon kings. This contrast returns in ancient Iran, where Yima is the peaceful sun king. The symbolic animal of the sun in Indo-Iranian culture is above all the horse. After an interregnum, when a new king had to be appointed, he was chosen at sunrise by the neighing of a horse. The sun horse obviously played a great role all over the Indo-European culture area and is attested also in Baltic folk songs.

Many of the gods in Indo-European religion show traces of solar qualities—among them, Mitra-Mithra (see MITHRAISM) in India and Iran, and Apollo (*q.v.*) in Greece—but the worship of the visible sun itself seems early to have faded from official religion. The deities possessing names derived from *svar-*, the root of Sūrya, such as *hvar* in Iran, Helios (*q.v.*) in Greece, Sol (*q.v.*) in Rome, and the visible sun in Germanic religion, are not included among the highest gods. Nevertheless their worship must once have been more important. A special Zoroastrian hymn is devoted to praise of the sun. Helios and Sol play considerable roles. Caesar (1st century B.C.) says that the Teutons worshiped the sun as a deity (*De bello Gallico*, 6, 21), and they celebrated sun festivals at those times of the year when the sun's appearance is of special purport.

In medieval Iran, sun festivals were celebrated as a heritage from pre-Islamic times. Such feasts are known also from India and Europe, where survivals are still found in popular customs. The centre of such festivals is occupied by fire rites and certain phallic ceremonies. The Indo-European character of sun worship is also seen in the conception of the solar deity, drawn in his carriage, generally by four white horses, common to many Indo-European peoples, and recurring in Indo-Iranian, Greco-Roman, and Scandinavian mythology.

During the later periods of Roman history sun worship gained in importance and ultimately led to what has been called a "solar monotheism." Influence from Oriental sun cults contributed to

an already existing tendency. Nearly all the gods of the period were possessed of solar qualities, and both Christ and Mithra acquired the traits of solar deities. The feast of *Sol Invictus* (unconquered sun) on Dec. 25 was celebrated with great joy, and eventually this date was taken over by the Christians as Christmas, the birthday of Christ.

**Other.**—The most famous type of solar cult is the sun dance (*q.v.*) of the Plains Indians of North America, a complex conglomeration of rites, very important for the understanding of the position occupied by the sun in the religion of North America. In the pre-Columbian civilizations of Mexico and Peru, sun worship was a prominent feature. In Aztec religion extensive human sacrifice was demanded by the sun gods Huitzilopochtli (*q.v.*) and Tezcatlipoca (see also AZTEC; ANDEAN CIVILIZATION: *Inca Culture*). The ball games found both in pre-Columbian civilization and among the Indians of modern times symbolize the movements of the sun and possessed ritual significance. In both Mexican and Peruvian ancient religion the sun occupied an important place in myth and ritual. The ruler in Peru was an incarnation of the sun god, Inti, the divine ancestor of the deity. In Japan the sun goddess, Amaterasu, who played an important role in ancient mythology and was considered to be the supreme ruler of the world, was the tutelary deity of the imperial clan, and to this day the sun symbols represent the Japanese state (see JAPANESE MYTHOLOGY).

**SUN YAT-SEN** (1866-1925), the leading figure in the Chinese revolution of 1911 and a national hero for all factions in modern China, was born in a farming village in Kwangtung province, near Canton. When he was 13 years old an elder brother who had emigrated to Hawaii sent for him; there he was educated and converted to Christianity in an Anglican school. After a brief return to his village, where he showed himself impatient with traditional practices and beliefs, Sun left for Hong Kong in 1883. He completed training in medicine there in 1892, and practised briefly in Macao, but his real interests lay in politics, not in medicine. His experience in Hawaii and Hong Kong, his belief in Christianity, and his western education combined to make him eager for change in China. Because Sun Yat-sen was poorly grounded in the classical tradition of Chinese culture he drew his support from Chinese who were western-oriented as he was. He traveled constantly to recruit followers and solicit funds from Chinese living in southeast Asia, Japan and the western world. He also had many close friends in England and the United States. For a decade, during much of which he used the name Nakayama, Japan provided help for some of his many abortive revolts, and at the end of his life he looked to the Soviet Union for aid.

#### Revolutionary Activities.

—In 1894 Sun Yat-sen made an unsuccessful attempt to present a memorial to the Viceroy Li Hung-chang urging reforms. The following year came the Japanese victory over China, and in its wake came Sun's first effort at rebellion in Canton. From then until the collapse of the

BROWN BROTHERS

SUN YAT-SEN

Manchu (Ch'ing) dynasty he tried time after time to bring about a revolution. His tactics formed a link between the conspiratorial techniques of the old secret societies, which had always been strong in south China, and the more broadly based nationalist movements of modern times. Until 1911 Sun's program was dominated by a determination to rid China of the Manchus. To this end he allied himself with many other discontented groups. Japan, where thousands of Chinese students were to be found, was the scene of the organization of the T'ung-meng-hui (Combined League Society) in 1905. Although a broad program was set forth for the organization, its members were most firmly united on the nationalist, anti-Manchu goal.

**Early Years of the Republic.**—Sun Yat-sen was abroad when the Manchu dynasty fell, late in 1911; he returned to China a national hero. After a brief period as president of the Chinese republic, he resigned in favour of Yüan Shih-k'ai (q.v.), whose military strength forced the revolutionaries to compromise with him. It then became clear that Sun's republican associates could not agree on a political program. Sun trusted in the new constitutional machinery to control Yüan, but the latter, who enjoyed the financial support of international loan consortiums, was able to flout the will of the revolutionaries. In 1913 Sun staged an unsuccessful revolt against Yüan. Thereafter, once again a fugitive and conspirator, Sun entered upon a discouraging period during which he bargained desperately for foreign support. Henceforth he was less confident and trusting, and more concerned with practical politics and the strategy of power.

After Yüan Shih-k'ai's death in 1916 China entered the chaotic period of war-lord rule. By dealing with war lords in the Canton area Sun was able to set up a government there. But his real strength lay not with the war lords but with the students, merchants and workers of the modern cities, for whom he was becoming the best-known and most articulate representative of the new spirit of nationalism. When the Soviet Union turned its attention to China, Sun's movement seemed to offer the best prospects for a "united-front" drive against imperialism. By agreement with a communist agent in 1923 Sun received Soviet support for the reorganization of the Kuomintang (q.v.). The party was recast on communist lines, with leadership securely in the hands of the central executive committee. Soviet military advisers trained and equipped the new army headed by Chiang Kai-shek, and Chinese communists, who joined the Kuomintang as individuals, contributed their organizational skills and propaganda to undermine the war lords in preparation for the northern expedition that was to bring national unification.

Sun did not live to carry out this program. Shortly before the northern expedition was to begin he made one last attempt to negotiate with the war lords. After his death in Peking on March 12, 1925, his last testament, a moving document that instructed his followers to carry on his work, became his legacy to modern China. Acclaimed as the leader of the Kuomintang and father of his country, he was for a time the centre of a state cult. In character and personality he was ideally suited for such a role, for his integrity, idealism, courage and sincerity had played a large part in bringing about the final victory. But the choice of Sun's writings as the centre of a new ideology was less fortunate.

**Writings.**—Sun had read widely and had drawn his ideas from many sources, but he was primarily an activist, intent upon the selection of materials suitable for the needs of the moment. His revolutionary program had begun to form in 1905 when he first enunciated the Three Principles of the People (*San Min Chu I*). "People's Rule" (nationalism), "People's Authority" (democracy) and "People's Livelihood" (sometimes given as socialism) became the slogans of the revolutionary movement. These principles received their fullest treatment in lectures Sun delivered at Canton shortly before his death. Under nationalism he denounced foreign controls on China and called for a rise in national spirit. His approach to livelihood owed much to the single-tax doctrines of Henry George (q.v.). Most significant was his treatment of democracy. He saw his party, the Kuomintang, acting as an elite, preparing the Chinese people for democracy against the day when they would be able to take over the task of governing themselves.

There again Sun's ideas were garnered from many sources. He distinguished between the four powers of the people (election, recall, initiative and referendum) and the five powers of the government (legislative, executive, judicial, civil service examinations and censorate). The skilled elite would run this elaborate machine just as an engineer would run a railroad train. Clearly this acceptance of the necessity of a period of one-party rule would delay indefinitely the establishment of democracy in China.

Perhaps because of the lack of a systematic treatment of the topics, Sun Yat-sen's writings were later made to serve many purposes. His mantle was claimed by Wang Ching-wei, who headed the puppet government at Nanking during the Japanese occupation, and also by Chiang Kai-shek, who carried the northern expedition to completion and headed the new Nationalist regime. Sun Yat-sen's widow, who was the sister of Mme Chiang Kai-shek, professed to find the program of the Communist government, which she served in high posts, in harmony with her husband's views. But it was above all the Nationalist government of Chiang Kai-shek that laid claim to Sun's memory. Sun Yat-sen's son, his first marriage, Sun Fo, held many important positions in the Nationalist administration. A magnificent mausoleum for Sun Yat-sen was erected on Purple Mountain outside Nanking under Sun's title as Kuomintang Leader, *Tsung-li*, remains his in perpetuity. See CHINA: History; see also references under "Sun Yat-sen" in the Index.

**SUPERCONDUCTIVITY** is exhibited by many pure metals and alloys when they are cooled to within a few degrees of absolute zero. Superconducting material is characterized by zero electrical resistance; i.e., electric charge is apparently transported through the specimen without friction, and no magnetic field can exist inside the material. The flux lines of a weak magnetic field are expelled from the specimen when it is cooled below its superconducting transition temperature; a moderately strong magnetic field, on the other hand, completely eliminates the superconducting state.

Superconductivity was discovered by H. Kamerlingh Onnes in 1911, but the perfect diamagnetism (q.v.) of superconductors was not reported until 1933 (W. Meissner and R. Ochsenfeld). The microscopic interpretation of the superconducting state has been given by J. Bardeen, L. Cooper, and J. R. Schrieffer, and N. Bogolyubov (1957). In the 1960s empirical verification of theory was made by B. D. Josephson (e.g., Josephson tunneling in semiconductors), P. W. Anderson, and others. Superconductivity seemed to be linked to superfluidity (q.v.) through the quantum-theory principle that matter has wave properties. A superconducting magnet with a coil only six inches long developed (1965) fields as intense as 132,000 gauss. See LOW-TEMPERATURE PHYSICS.

See G. Rickayzen, *Theory of Superconductivity* (1965). (J. R. R.: X)

**SUPERFLUIDITY**, a phenomenon that occurs in liquid helium when it is cooled to within about 2.2° of the absolute zero of temperature; i.e., when it is cooled below -271° C (-456° F). This temperature, the so-called lambda point, marks the transition between two phases: liquid helium I and the low-temperature liquid helium II. The low-temperature phase appears to be a mixture of two fluids, the normal and the superfluid, with the fraction of superfluid increasing as the temperature is lowered. Certain properties of the superfluid give rise to its name—it can pass with ease through very narrow capillaries or small cracks, thereby showing no viscosity, and it conducts heat extremely well.

It is known that the helium molecule is a Bose-Einstein particle, and the phase transition at -271° C is apparently closely related to the condensation mechanism of an ideal Bose-Einstein gas. See HELIUM; LANDAU, LEV DAVIDOVICH; LOW-TEMPERATURE PHYSICS; SUPERCONDUCTIVITY.

See F. London, *Superfluids*, 2nd rev. ed., 2 vol. (1961-64).

(J. R. RE.)

**SUPERIOR**, the most northwesterly city of Wisconsin, is situated between the bays of St. Louis and Allouez on Lake Superior; it is the seat of Douglas County. With its twin port, Duluth (*q.v.*), it forms the western terminus of the St. Lawrence Seaway; through the natural harbour shared with Duluth are shipped iron ore, coal, grain, and crude oil. The Superior harbor shipping facilities include four ore docks, averaging 2,250 ft. (686 m.) in length and 80.5 ft. (24.5 m.) in height, with a total capacity of 500,000 gross tons; eight grain elevators with a 30,500,000-ton capacity; and ten coal docks with a capacity of more than 3,500,000 tons. Crude oil arrives at Superior from Canada through a 1,127-mi. (1,814 km.) pipeline to be refined. Other industries include shipbuilding and the manufacture of coal briquettes, flour, beer, and dairy and wood products.

Pop. (1960) city 33,563; Duluth-Superior standard metropolitan statistical area (St. Louis County, Minn., and Douglas County, Wis.) 276,596. For comparative population figures, see table in WISCONSIN: *Population*.)

The Superior area was occupied originally by the Sioux (Dakota) and Chippewa Indians. In 1655 the Jesuit Father Claude Allouez built a mission near the bay that bears his name. Pierre Esprit Radisson and Médard Chouart des Groseilliers arrived in 1661. Trading posts were established about 1678 by Daniel Greysolon, Sieur Dulhut (or Duluth) and about 1820 by the Hudson's Bay Company. Permanent settlement did not take place until 1853, one year after the government survey made by George R. Stuntz. Lands were purchased, and settlement was made at the eastern end of present Superior, the Allouez Bay area, where names of avenues recall early speculators, such as William Wilson Corcoran, former Sen. Robert J. Walker, and Congressman John C. Breckinridge. A second settlement was made in 1882 by Gen. John H. Hammond; he organized the Land and River Improvement Company, which platted the townsite of West Superior on St. Louis Bay. The third townsite was South Superior. Both West and South Superior were joined with the original East End settlement, and the united municipality was incorporated as the City of Superior in April 1889. Between 1941 and 1959 the city was administered by a city manager and seven councilmen; then the mayor-council form of government was adopted.

Superior is the site of a Wisconsin State College, opened in 1896. The city has public and parochial high schools, a Carnegie Library with several branches, and the Douglas County Historical Museum.

Proximity to Lake Superior, numerous small lakes, and Brule River, famous for trout fishing and canoeing, make the area a tourist haven. Along the St. Louis River is Billings Park. Manitou Falls, the largest in Wisconsin, is 14 mi. S of Superior.

(E. F. GR.)

**SUPERIOR, LAKE**, named from the French *Lac Supérieur*, meaning "Upper Lake," and the most northwesterly of the five Great Lakes of North America, is the largest body of fresh water in the world. It is bounded on the east and north by the province of Ontario, on the west by the state of Minnesota and on the south by Wisconsin and Michigan. The general form of Lake Superior is that of a wide crescent convex toward the north. It is 383 mi. (616 km.) long (on a straight line) in an east-west direction and its greatest width is 160 mi. (257 km.). The surface area of the lake is 31,800 sq.mi. (82,362 sq.km.) and the area of its drainage basin, exclusive of lake area, is 48,200 sq.mi. (124,838 sq.km.). The mean height of the lake above sea level is 602 ft. (183 m.), 22 ft. (6.7 m.) above that of Lake Huron, to which it is joined at its eastern extremity by the St. Marys river. Its maximum recorded depth is 1,333 ft. (406 m.), 731 ft. (223 m.) below sea level. (For comparison with the other Great Lakes, a discussion of their origins, connections, utilization, etc., see GREAT LAKES, *THE*.)

**History.**—Pierre Radisson and Médard des Groseilliers traveled extensively on Lake Superior in 1659-60 and returned to the east with a valuable cargo of furs. Father Claude Jean Allouez circumnavigated the lake by canoe in 1667 and prepared a map of

the lake which was the most accurate drawn until recent times.

Daniel Greysolon, Sieur Dulhut, known as Duluth, opened Lake Superior to active trading in 1679. Fur trading by the French then flourished at intervals, but in 1763 the entire region was ceded to Great Britain. Lake Superior was under formal British control until the close of the American Revolution in 1783; after that, trade continued in the hands of the British until 1817 when John Jacob Astor's American Fur Company took control of trade south of the international boundary line.

**Physiography.**—The lake receives the drainage of approximately 200 rivers. The largest tributary is the Nipigon river, entering from the north and draining Lake Nipigon, and the second largest is the St. Louis river, entering from the west at Duluth. Other principal rivers of the north shore are the Pigeon, which forms the international boundary northwestward from the lake, the Kaministiquia, which enters Thunder bay at Fort William, the Pic, the White and the Michipicoten. No large rivers empty into the lake from the south. The outlet, the St. Marys river, carries a mean annual discharge of 73,100 cu.ft. per second.

Going outward from the lake in any direction except the southeast, one soon comes to an escarpment above which is a distinct upland overlooking the lake basin. At many places the escarpment, 400 to 800 ft. (122 to 244 m.) high, descends into water 500 to 800 ft. (152 to 244 m.) deep. The coast line is picturesque, the north shore particularly being indented by deep bays surrounded by high cliffs. The principal islands in the lake are Isle Royale, 44 mi. (71 km.) long, near the northwestern shore, which is a U.S. national park; Michipicoten, 17 mi. (27 km.) long, in the eastern part; and the Apostle Islands, a group off the Wisconsin shore in the southwest. Abandoned shore lines indicate that the lake once stood about 200 ft. (61 m.) higher and drained southwestward to the Mississippi river while glacial ice occupied the eastern part of the basin, and that later the lake discharged into Green Bay of Lake Michigan before its present outlet was uncovered by melting of the ice sheet.

The ancient (Precambrian) rocks which nearly surround Lake Superior contain valuable mineral deposits. For many years the Lake Superior district was the largest producer of copper in the United States. Iron ore was mined and smelted locally in the Negaunee and Marquette areas during 1848-54. The opening in 1855 of the ship canal along St. Marys river (see SAULT SAINTE MARIE) was followed by regular shipment of iron ore from the Marquette district to the lower lakes. Subsequently iron was produced from many parts of the Lake Superior district, including the Mesabi range in Minnesota (see IRON AND STEEL INDUSTRY). By the second half of the 20th century high-grade iron ores were becoming scarce but improved technology permitted the use of abundant taconite and other low-grade ores.

**Harbours and Commerce.**—Lake Superior is fairly well provided with natural harbours, and works of improvements have created additional harbours at various points. Fort William at the mouth of the Kaministiquia river and Port Arthur, 4 mi. (6.4 km.) distant, with an artificial harbour, are the lake terminals of two Canadian transcontinental railway systems and they ship grain from the western prairies. Taconite Harbor, Minn., formed by joining two islands to the shore with breakwaters, and Two Harbors, Minn., on a natural bay improved with breakwaters, are important shipping points for iron ore. Duluth, Minn., and Superior, Wis., are located at the western end of the lake on a large natural harbour, formed by a sand bar across the mouth of the St. Louis river, with two entrances maintained by piers. This port ships a large tonnage of iron ore, grain and flour. The principal ports along the south shore of the lake are Ashland, Wis., with a harbour formed by a breakwater; Houghton and Hancock, Mich., located on a 25-mi. (40 km.)-long canal across the Keweenaw peninsula; and Marquette, Mich., with an artificial harbour. These ports ship large tonnages of ore. The traffic to and from Lake Superior via the United States and Canadian locks at Sault Ste. Marie amounts to approximately 100,000,000 tons annually.

A large part of the land surrounding Lake Superior is very sparsely settled and much of it is a wilderness. Extensive forests are held in federal, state, provincial and private timber lands.

Hunting and sport fishing in season and tourism in the summer months form the basis for an increasingly important recreation industry in the region.

**BIBLIOGRAPHY.**—Canadian Hydrographic Service, *Great Lakes Pilot*, vol. iii and charts (annually); U.S. Army Corps of Engineers, U.S. Lake Survey, *Great Lakes Pilot* and charts (annually); G. L. Nute, *Lake Superior* (1944). (J. L. НН.)

**SUPERNATURALISM**, a belief in an otherworldly reality that, in one way or another, is found in all forms of religion.

The idea of nature is unknown to primitive man, who inhabits a wonder world charged with the sacred power of *mana* (q.v.) and spirits. Primitive man associates the uncanny, the unusual or the powerful of any kind (including so-called natural phenomena such as the rising of the sun and the prowess of a warrior) with the presence of a sacred power.

In the higher religions, a gulf usually is created between the supernatural and natural realms. Thus, for example, Christianity distinguishes between this world and the Kingdom of God, or nature and grace, or earth and heaven. Hinduism in its various forms draws a polar distinction either between nature and spirit or between *samsara* (the world) and Brahman-Atman (the deity); and in the Vedanta school of Hinduism the world becomes *maya* (illusion).

Early Buddhism drew a radical distinction between the world as pain and suffering (*samsara*) and the redemptive goal of the disciple (*nirvana*), while refusing to look upon *nirvana* as a supernatural realm of existence. Certain later schools of Mahayana Buddhism postulated a mystical and paradoxical identification of *nirvana* and *samsara*. This identification of the world and the Beyond, the profane and the sacred, is virtually unique in the history of religions, although it has a parallel in the Hasidic school of Jewish mysticism.

Far eastern religions have never abandoned their primitive roots; and in Confucianism, Taoism and various sects of Chinese and Japanese Buddhism no genuine distinction is made between the natural and the supernatural.

The secularization of modern western civilization has created a gulf between the natural and the supernatural resting upon the idea of an autonomous nature existing apart from the influence or control of God. Here, the world becomes a profane reality wholly isolated from the sacred. This situation led to Nietzsche's proclamation of the "death" of God and his condemnation of Christianity as a flight from reality and an escape to an otherworldly nothingness.

So pervasive is the modern experience of the unreality of the supernatural realm that certain schools of Protestant theology have collapsed the distinction between the natural and the supernatural. This is fully apparent in process theology, as exemplified by H. N. Wieman, and partially so in the existentialist school of dialectical theology led by Paul Tillich and Rudolf Bultmann (see NEO-ORTHODOXY). In the one case is found an affirmation of a rational and scientific universe that will admit the existence neither of a supernatural realm nor of a God who exists wholly apart from the world; in the other, a dialectical conception of faith that conceives it as leading the believer in some sense beyond the world while at the same time insisting that true faith leads the Christian into the depths of his present existence in such a way as to exclude the possibility of a belief in an actual supernatural realm.

**SUPERNOVA**; see NOVA AND SUPERNOVA.

**SUPERSTITION**, an irrational belief, half belief, or practice. Those who use the term imply that they have certain knowledge or superior evidence for their own scientific, philosophical, or religious convictions (see KNOWLEDGE, THEORY OF). But the word is ambiguous, and it seems likely that it cannot be used except subjectively. With this qualification in mind, superstitions may be classified roughly as religious, cultural, and personal.

Every religious system tends to accumulate superstitions as

peripheral beliefs—a Christian, for example, may believe that in time of trouble he will be guided by the Bible if he opens it at random and reads the text that first strikes his eye. Over and beyond these, however, one man's religion is another man's superstition: Tacitus called Christianity a pernicious superstition; Constantine called paganism superstition; Catholic veneration of religious images, and the saints appears superstitious to many Protestants. Christians regard many Hindu practices as superstitious; adherents of all "higher" religions may consider the Australian aborigine relation to his totem superstitious; and all religious beliefs and practices may seem superstitious to the person without religion.

Superstitions that belong to the cultural tradition (in some cases inseparable from religious superstition) are enormous in the variety. Nearly all men, in nearly all times, have held, seriously or half seriously, "irrational beliefs" concerning methods of warding off ill or bringing good, foretelling the future, and healing or preventing sickness or accident. A few specific beliefs, such as that in the evil eye or in the efficacy of amulets, have been found in most periods of history and in most parts of the world. Others may be limited to one country, or one region, or one village, to one family or one social or vocational group. Some of them stem from a body of outmoded learning (such as astrology), from a superseded religion (as, according to Margaret Murray, the medieval witch cult in Europe, traces of which probably can still be seen represents the remains of pre-Christian pagan religion), from magical practices whose original significance has been long forgotten (as touching wood when mentioning a run of good fortune or merely from a conservatism that continues to accept without question explanations or ideas once they have become current).

And, finally, people develop personal superstitions: a schoolboy writes a good examination paper with a certain pen, and from then on that pen is "lucky"; a horseplayer may be convinced that gray horses run well for him.

Superstition, defined as above, has been deeply influential in world history. It would be impossible to estimate how many people have been hanged or burned as adults or drowned in infancy; how many battles have been fought, drawn, or evaded, how many journeys undertaken or withdrawn from because of superstition. Being irrational, superstition, one would say, must recede before education and, especially, science. Once an astronomer has been able to provide a natural explanation for solar eclipses and predict to the day and minute the occurrence of the next one, those who are within reach of his voice or his writings are much less likely to believe that an eclipse is a sign of the gods' disapproval of some act of man. Many superstitious observances are little more than automatic habitual reactions: a physicist may comment on a black cat's crossing his path; a cultured Chinese may consult his astrologer, or an educated American may glance at the horoscope in his newspaper every day. Others may represent nothing more than an unvoiced notion that one might as well not invite trouble—it is just as easy to walk around a ladder as under it. If the question is put to him seriously, the boy will acknowledge that the pen is no more lucky than any other, and the horseplayer will admit that gray horses have failed him. But even in a day when objective evidence is valued very highly, there are few people who, if pressed, would not admit to cherishing secretly one or two irrational beliefs, or superstitions.

**SUPERTONIC**, in music, the second degree of the diatonic scale, as D in the scale of C, that is, the note next above the tonic, whence its name. See SCALE.

**SUPILO, FRANO** (1870-1917), Croatian patriot who played a significant role in the conflicts preceding the birth of an independent South Slav state. He was born into a peasant family on Nov. 30, 1870, at Cavtat in Dalmatia. From 1900 he edited *Novi List*, a Croatian newspaper at Rijeka, which strongly opposed Austrian and Hungarian encroachment on Croatian interests. In 1905, together with Pero Čingrija and Josip Smoljaka, he drew up the Rijeka Resolution, which led to the formation of a new political group, the Croato-Serb coalition. Supilo became the first

president of this group and the instigator of anti-Austro-Hungarian activities in Croatia. In order to discredit him the Austrian Foreign Office supplied documents, allegedly proving his collusion with Serbia, to the publicist Heinrich Friedjung (*q.v.*); but Supilo and other coalition leaders then sued Friedjung for defaming them, and they were vindicated at a sensational trial in Vienna (December 1909), when the documents were shown to be forgeries. Even so, Supilo gave up his presidency, and the coalition adopted an opportunist attitude toward Budapest.

During World War I, Supilo went over to the Allied side and, together with Ante Trumbić and Ivan Meštrović, started the movement for the liberation of the South Slavs. From a talk with S. D. Sazonov, the Russian foreign minister, he learned of the negotiations between the Allies and Italy. The Allies were promising that extensive territories along the eastern Adriatic coast, to be taken from Austria-Hungary, should go to Italy. Supilo and his friends, who had formed the Yugoslav Committee, warned the Allied leaders against this and propagated the idea of establishing a South Slav state. Favouring a federalist constitution for this union as a security valve against Serb predominance, he came into conflict with Nikola Pašić (*q.v.*). Supilo proposed that agreement with Serbia on the constitution of the future Yugoslavia should precede all efforts for unification. Outvoted on this point, he resigned from the Yugoslav Committee; but shortly before his death, which took place in London on Sept. 23, 1917, he endorsed the Declaration of Corfu of July 20, which Trumbić and the committee had negotiated with Pašić.

See Josip Horvat, *Frano Supilo* (1938).

(A. S. PA.)

**SUPPÉ, FRANZ VON** (real name FRANCESCO EZECHIELE ERMENEGILDO SUPPÉ DEMELLI) (1819–1895), Austrian composer of light operas written in the style of Offenbach, who greatly influenced the development of Austrian and German light music up to the middle of the 20th century. Born at Spalato (Split) on April 18, 1819, he came from a family of Belgian origin that had lived in Italy for two generations. In his youth he went to Vienna, where he studied composition with S. Sechter and I. X. Seyfried and took advice from Donizetti. Later he conducted at the Theater an der Wien, the Josephstadt, and other theatres in Vienna. In 1841 he wrote the incidental music for a play at the Josephstadt Theatre and thereafter wrote numerous comic operas and operettas, as well as incidental music, including the overture for the play *Dichter und Bauer* ("Poet and Peasant," Vienna, 1846). His most successful comic operas were produced in Vienna and include *Leichte Kavallerie* (1866), *Fatinitza* (1876), and *Boccaccio* (1879). He also wrote choral works, a symphony, and string quartets. He died in Vienna on May 21, 1895.

See O. Keller, *Franz von Suppé der Schöpfer der deutschen Operette* (1905); E. Rieger, *Offenbach und seine Wiener Schule* (1920).

**SUPPLY AND DEMAND.** The celebrated "law of supply and demand" in economics can be formulated simply by saying that for each commodity some price must exist that will cause the supply and the demand for any commodity or source to be just equal. Such a price will "clear the market." This principle of supply and demand was called the "first, greatest, and most universal principle" of political economy by one of the early giants among economists, Thomas R. Malthus. His enthusiasm may have carried him a little too far, but probably not by very much.

Supply and demand can be spoken of in two possible contexts, one that concerns individual commodities, and another that considers the aggregate of all commodities taken together. In discussing individual commodities the first point to be made clear is that supply, or demand, should be thought of not in terms of what is actually supplied, or demanded, in any given instance but rather in terms of schedules of potential supplies, at various possible prices, and of potential demands. One would indicate the willingness of suppliers to sell at various prices, the other the willingness of potential customers to buy. At any one price the two may or may not match. It is the function of markets to make them match.

**Characteristics of Demand.**—A curve relating willingness to buy to various prices is usually drawn with a "negative" slope, indicating that this willingness declines as prices rise. The justi-

fication for this practice can be seen if the two major types of markets are considered separately, first the market for consumer goods and services, then the market for services of the factors of production, land, labour, and capital. In the first it is discovered that as the price of a certain commodity rises, more of any consumer's income will be lost on it should the consumer maintain the volume of his purchases. Less would be left over for other commodities, whose purchases must therefore decline.

But as purchases of some alternative commodity decline, the alternative commodity becomes scarcer—and hence more valuable—in the eyes of the consumer. It is likely, therefore, that the consumer will become increasingly reluctant to sacrifice more of it, and prefer to reduce instead his purchases of the commodity whose price has risen. This causes the "demand curve" to have a negative slope in the market for each individual consumer good.

What causes the demand curve in the market for productive factors to have a similar slope? Naturally an enterprise would not hire any such factor unless its contribution to the revenues of the firm were sufficient at a minimum to cover the cost of that factor. For example, in the case of labour, an employer seeking to maximize profits for his firm would have to continue to hire labourers as long as—for each additional workman—the product exceeded the wage. Suppose, however, that each additional worker's contribution to the product tended to decline, due to the operation of the law of diminishing returns. Then the demand for labour, and employment, could continuously increase only if the wage continuously fell. That fact accounts for the negative slope of the demand.

The steepness of such curves reflects what has come to be known as the "elasticity" of the curve, or better, the "responsiveness" of demand to changes in price. If, for example, a 1% decline in price causes demand to increase by 2%, the elasticity of demand is said to be equal to two—that is, equal to the ratio of the percent change in demand to the percent change in price. This elasticity depends in the first instance on the availability of substitutes.

**Characteristics of Supply.**—Curves relating willingness to sell individual commodities to some range of possible prices are customarily drawn with a "positive" slope, indicating that this willingness increases as prices increase. In the commodity market, one justification for this practice runs as follows. Productive resources are deployed in such a way that producers make the highest possible profit. Should prices rise in a certain line, say ladies' hats, profits there would rise and attract resources away from competing uses. In these competing lines, supplies would therefore fall, driving up prices there. Should competing prices rise very quickly, the redeployment of resources to the production of hats would not go very far, unless the price of hats was increased still further. There is, therefore, a positive correlation between the supply and the price of hats.

In the factor markets supply curves are drawn similarly, and for similar reasons. If a certain factor has been earning a given return in a particular employment, it can be attracted to any other—"new"—line only by the offer of a higher return. As the transfer proceeds, the supply of factors in old employments falls, the marginal products there rise, and the returns foregone by shifting into the "new" line increase progressively. To keep attracting more and more factors, "new" lines will have to keep offering progressively higher returns. The supply, again, is positively correlated with the return; *i.e.*, with the price offered.

**Equilibrium.**—Schedules of willingness to buy and sell generally reveal some price at which the two come out to be equal. This is the "equilibrium" price; at this price all sellers can find buyers and all buyers sellers. Suppose a price obtains such that some sellers cannot find buyers. Disappointed sellers will then cut prices in order to lure buyers away from their competitors. Suppose, on the other hand, a price obtains at which some would-be buyers cannot find sellers. They will then offer to pay higher prices to divert supplies away from their rivals. Any departure from an equilibrium price seems, therefore, automatically to be corrected by market forces pushing the price toward equilibrium.

This happy result is sometimes destroyed by speculation. Suppose that demand rose above supply; the price would then show a

tendency to rise. If all went properly, any rise in price should lower demand and raise supplies. If, however, an initial increase in price leads speculators to believe that prices will continue to rise, then they may withdraw more supplies from the market rather than add to them, hoping to do better by themselves later, when prices are yet higher. It is easy to see that this sort of thing may lead to a greater disequilibrium rather than to a restored balance between supply and demand. Where there is the possibility of such speculation, any equilibrium is spoken of as being "unstable."

**Aggregates.**—The problem of the supply and demand for all commodities taken together is very complex, and, therefore, a few points only are discussed here.

Aggregate supplies depend on the inducements offered to productive factors to produce. In the case of labour, it could be argued that increases in total labour hours worked involve reductions in the leisure enjoyed by the working population. The less leisure left to them, the higher the compensation for additional reduction would have to be. Once every man is employed this probably holds true. With unemployment, however, changes in labour hours supplied involve changes in the number of men working rather than in the division of time between work and leisure for each man. In that case, more men could probably be hired at the going wage, and the supply curve of labour would have to be drawn as a horizontal line up to the point of full employment.

The same would hold for other factors of production, such as land and capital. The overall supply of land would stay more or less fixed. Its supply curve past full employment would therefore be vertical. The supply of capital could grow as long as people were willing to produce capital rather than consumer goods. The rate of growth of capital probably depends, in part at least, on the inducement offered to potential investors to reduce consumption. The lower their consumption levels are pushed, the higher would have to be the compensation offered for further reductions.

In considering aggregate demand and what determines the total of expenditures on goods and services it is clear that since the total of expenditures determines the total of incomes, demand curves can no longer be drawn in relation to "price" with incomes constant, as was done with individual commodities. Instead, economists have examined the determinants of three broad classes of expenditures, those of consumers, those of investors in capital goods, and those of the government. The first seems on the whole to be related to the (changing) level of income, the second to expectations of future markets, and the last to political considerations. Once these demands, added up, are brought to bear on available supplies, supply and demand again determine a price—this time the price level. It is debatable, however, whether this is an equilibrium price in quite the same sense as before.

**SUPREME COURT OF JUDICATURE**, in England, a court established by the Judicature Act, 1873, consisting of the Court of Appeal and the High Court of Justice (*qq.v.*). See also **COURT: England: Civil Courts: The Supreme Court.**

**SUPREME COURT OF THE UNITED STATES, THE**, stands at the apex of a dual system of courts: state and federal. This position accounts for the distinctive and even paradoxical character of the court's function: it is a conventional tribunal whose authority can be exercised only in the decision of ordinary lawsuits, and at the same time, as the final expositor of the United States constitution, it is the voice and symbol of the aspirations of the nation. Within the framework of litigation, the supreme court marks the boundaries of authority between state and nation, state and state and government and citizen.

## ORGANIZATION AND POWERS

**Establishment and Membership.**—The articles of confederation, which held together the American states from 1781 until adoption of the constitution, did not provide for a supreme court.

But the articles did authorize congress to appoint courts of appeal in cases of naval captures, and such a court functioned until 1781 deciding more than 100 appeals from state courts. In a limited sense this tribunal was a precursor of the present supreme court. The framers of the constitution in 1787 concluded that a supreme judicial tribunal was required in a political system that gave limited powers to the centre and that, even before the adoption of the Bill of Rights through amendments, imposed specific prohibitions on the state and national governments. Article iii, section I, of the constitution provides:

The judicial Power of the United States shall be vested in one supreme Court, and in such inferior Courts as the Congress may from time to time ordain and establish. The Judges, both of the supreme and inferior Courts, shall hold their Offices during good Behavior, and shall, at stated Times, receive for their Services, a Compensation, which shall not be diminished during their Continuance in Office.

The jurisdiction of the federal courts is defined in succeeding provisions of article iii. The major heads of jurisdiction reflect the special mission of these courts conceived as tribunals relatively detached from local pressures and biases. The authority of the federal courts extends to cases arising under the constitution, laws or treaties of the United States, controversies to which the United States is a party, controversies between states or between citizens of different states, cases of admiralty and maritime jurisdiction and cases affecting ambassadors, other public ministers and consuls. Of these courts, only the supreme court is given by article iii a status independent of the will of congress. Since the constitution is silent on such matters as the size of the court and the scope of its appellate jurisdiction in the judicial hierarchy, however, the supreme court itself is subject in important respects to congressional action.

The first Judiciary act, passed on Sept. 24, 1789, provided for a chief justice and five associate justices. In 1807 the membership was increased by law to seven, in 1837 to nine and in 1863 to ten. In 1866, as part of the effort by congress to curb the appointing power of Pres. Andrew Johnson, a statute reduced the membership to seven as vacancies should occur, and actually the court declined to eight members. But in 1869 an increase to nine was provided, at which the size of the court has remained. Tenure is during good behaviour, subject to expulsion by conviction on impeachment as provided in article ii, section 4, of the constitution. One justice of the court has been impeached—Samuel Chase who was acquitted in 1805. By an act of 1937, a member of the court who has served for ten years or more may retire with full compensation upon reaching the age of 70.

Appointments to the supreme court, as to the lower federal courts, are made by the president with the advice and consent of the senate. Nine nominations have been rejected by the senate, the latest being that of John J. Parker in 1930. All appointees have been lawyers, but beyond this there has been no pattern of selection. It can be said that geographic distribution has been a factor as well as the political outlook of the nominees, not so much their partisan affiliation as an outlook on problems of statecraft congenial to the chief executive and the senate. It must be added that a number of justices, enjoying the emancipation of the robe, have surprised and disappointed those who were responsible for their appointment.

The 14 members of the court who served as chief justice of the United States, with terms of service, follow:

John Jay (1789-95)	Melville W. Fuller (1888-1910)
John Rutledge (1795)	Edward D. White (1910-21)
Oliver Ellsworth (1796-1800)	William H. Taft (1921-30)
John Marshall (1801-35)	Charles E. Hughes (1930-41)
Roger B. Taney (1836-64)	Harlan F. Stone (1941-46)
Salmon P. Chase (1864-73)	Fred M. Vinson (1946-53)
Morrison R. Waite (1874-88)	Earl Warren (1953- )

The associate justices, with their terms of active service, are as follows:

John Rutledge (1789-91)	Samuel Chase (1796-1811)
William Cushing (1789-1810)	Bushrod Washington (1798-1829)
James Wilson (1789-98)	Alfred Moore (1800-1804)
John Blair (1789-96)	William Johnson (1804-34)
James Iredell (1790-99)	Brockholst Livingston (1806-23)
Thomas Johnson (1792-93)	Thomas Todd (1807-26)
William Paterson (1793-1806)	Joseph Story (1811-45)

Gabriel Duval (1812-35)  
 Smith Thompson (1823-43)  
 Robert Trimble (1826-28)  
 John McLean (1829-61)  
 Henry Baldwin (1830-44)  
 James M. Wayne (1835-67)  
 Philip P. Barbour (1836-41)  
 John Catron (1837-65)  
 John McKinley (1837-52)  
 Peter V. Daniel (1841-60)  
 Samuel Nelson (1845-72)  
 Levi Woodbury (1845-51)  
 Robert C. Grier (1846-70)  
 Benjamin R. Curtis (1851-57)  
 John A. Campbell (1853-61)  
 Nathan Clifford (1858-81)  
 Noah H. Swayne (1862-81)  
 Samuel F. Miller (1862-90)  
 David Davis (1862-77)  
 Stephen J. Field (1863-97)  
 William Strong (1870-80)  
 Joseph P. Bradley (1870-92)  
 Ward Hunt (1873-82)  
 John M. Harlan (1877-1911)  
 William B. Woods (1880-87)  
 Stanley Matthews (1811-89)  
 Horace Gray (1881-1902)  
 Samuel Blatchford (1882-93)  
 Lucius Q. C. Lamar (1888-93)  
 David J. Brewer (1889-1910)  
 Henry B. Brown (1890-1906)  
 George Shiras, Jr. (1892-1903)  
 Howell E. Jackson (1893-95)  
 Edward D. White (1894-1910)  
 Rufus W. Peckham (1896-1909)  
 Joseph McKenna (1898-1925)

Oliver W. Holmes (1902-32)  
 William R. Day (1903-22)  
 William H. Moody (1906-10)  
 Horace H. Lurton (1909-14)  
 Charles E. Hughes (1910-16)  
 Willis Van Devanter (1910-37)  
 Joseph R. Lamar (1911-16)  
 Mahlon Pitney (1912-22)  
 James C. McReynolds (1914-41)  
 Louis D. Brandeis (1916-39)  
 John H. Clarke (1916-22)  
 George Sutherland (1922-38)  
 Pierce Butler (1922-39)  
 Edward T. Sanford (1923-30)  
 Harlan F. Stone (1925-41)  
 Owen J. Roberts (1930-45)  
 Benjamin N. Cardozo (1932-38)  
 Hugo L. Black (1937- )  
 Stanley F. Reed (1938-57)  
 Felix Frankfurter (1939-62)  
 William O. Douglas (1939- )  
 Frank Murphy (1940-49)  
 James F. Byrnes (1941-42)  
 Robert H. Jackson (1941-54)  
 Wiley B. Rutledge (1943-49)  
 Harold H. Burton (1945-58)  
 Tom C. Clark (1949-67)  
 Sherman Minton (1949-56)  
 John M. Harlan (1955- )  
 William J. Brennan (1956- )  
 Charles E. Whittaker (1957-62)  
 Potter Stewart (1958- )  
 Byron R. White (1962- )  
 Arthur J. Goldberg (1962-65)  
 Abe Fortas (1965- )  
 Thurgood Marshall (1967- )

the supreme court read as conferring original jurisdiction on the court beyond the warrant of article iii was declared invalid, the case was therefore dismissed for lack of jurisdiction, and a direct clash with the defendant, Pres. Thomas Jefferson's secretary of state, was averted. The irony of this act of abstention tended to blunt in popular consciousness the immediate effect of the court's assertion of power.

Judicial review of legislation of the states brought more severe immediate repercussions. Indeed the very power of the court to review decisions of state courts was vigorously challenged when it was laid down in an opinion of Justice Joseph Story in 1816, in the case of *Martin v. Hunter's Lessee*. For a number of years thereafter efforts were made in congress to repeal the section of the Judiciary act that conferred on the supreme court this appellate jurisdiction over state tribunals in cases turning on constitutional issues. No state or section had a monopoly on this spirit of resistance. Originally centred in the southern states, it was echoed on occasion in the North, as when in the period before the Civil War the state courts were held to the enforcement of the federal Fugitive-Slave law. A further ironic turn, in a subject studded with ironies, is that after the Civil War the power of judicial review served as an instrument of reconciliation, for the court declared unconstitutional, as bills of attainder, federal and state laws imposing test oaths intended to disqualify Confederate sympathizers from holding office or practising the professions.

Judicial review of legislation is not the only method whereby the court serves to maintain the constitutional order. Executive, administrative and judicial action also are subject to review in the supreme court. Moreover, some of the frictions and confusions of authority incident to a federal system are resolved in the court through the adjudication of controversies between states themselves, as for example those over boundaries or the allocation of water rights in interstate rivers. In this arbitral capacity the court serves as a substitute for diplomacy or war. Still another unifying function of the court is the interpretation of federal statutes, which would otherwise be subject to divergent applications in the lower courts.

For a time the supreme court attempted a further unifying role, that of developing a body of federal common (nonstatutory) law in cases arising in the diversity-of-citizenship jurisdiction of the federal district courts, but this enterprise introduced some anomalies of its own and it came to an end in 1938 with a decision holding that in such cases the common law to be applied is that of the state in which the federal district court is situated.

**Jurisdiction and Procedure.**—Since the functions of the court are performed within the framework of ordinary litigation, it is necessary to outline the procedures by which cases reach the court and are there decided. Relatively few cases are brought in the original jurisdiction of the court. These are controversies between states, between a state and the United States or between a state and citizens of another state, and cases affecting ambassadors, other public ministers and consuls. The great bulk of the court's business comes to it in its appellate jurisdiction. Depending on the nature of the decision in the state or lower federal court, the route to the supreme court is by appeal or certiorari. The difference between the two is that an appeal invokes the obligatory jurisdiction of the supreme court, certiorari its discretionary jurisdiction.

The development of this bifurcated jurisdiction reflects a response by congress to a long struggle by the court to cope with the volume of cases annually docketed. In 1891 a measure of relief was afforded by the Circuit Court of Appeals act, setting up intermediate courts (of which there are 11, in ten circuits and the District of Columbia) having final authority over appeals from federal district courts save in cases of exceptional public importance. The same act put a belated end to the circuit-riding duties of supreme court justices. The Judiciary act of 1925 carried the reforms further. Sponsored by the court itself, under the aegis of Chief Justice Taft, the act greatly limited the obligatory jurisdiction and gave the court a large measure of control of its business by subsuming most classes of cases under the head

Only two chief justices, Edward D. White and Harlan F. Stone, were advanced to that office while serving as associate justices. Charles Evans Hughes (chief justice 1930-41) served as associate justice before resigning in 1916 to run for president.

John Rutledge was an associate justice (1789-91) but resigned to become chief justice of the supreme court of South Carolina; he received a recess appointment as chief justice of the U.S. supreme court in 1795, but his nomination for an unlimited term was rejected by the senate. The longest tenure, 34 years and 8 months, was that of Stephen J. Field.

**Basic Functions.**—In maintaining the constitutional order, the supreme court from an early date has exercised the power of declaring acts of congress or of the state legislatures to be unconstitutional. Neither branch of this power of judicial review is expressly conferred by the constitution, and neither was established without intense partisan and sectional resentment.

Judicial review of acts of congress, assumed to be proper in a case in 1796, was established as a function of the court in 1803 in the celebrated case of *Marbury v. Madison*. The opinion of Chief Justice Marshall, adopting in substance the argument of Alexander Hamilton in no. 78 of the *Federalist*, deduced the power as a logically inevitable element of the judicial process: if in the decision of a case it appears that a statute and the constitution are in conflict, the court, which is bound to decide according to law, must prefer the higher to the inferior law. This analysis, assuming as it does that the court rather than congress or the electorate has the controlling judgment on such issues of conflict, is not free of the question-begging fallacy, as is suggested by the practice in the Swiss federation, where the constitutional validity of acts of the federal legislature is not examinable by the supreme court. But this is by no means to countenance the charge of usurpation that has sometimes been leveled at Marshall. There were precedents for judicial review of legislation in the practice of the privy council in relation to the colonies and of U.S. state courts after the Revolution. Moreover, there were references in the Constitutional Convention, though oblique, to the function of judicial review in litigation as a preferable alternative to a council of revision exercising a kind of veto power over legislation deemed invalid.

The doctrine of judicial review was made more palatable to the anti-Federalist critics of Marshall by the actual consequence of the doctrine in the *Marbury* case itself: an act of congress which

of review by certiorari; these can be disposed of on the moving papers, without full briefs or oral argument, where they do not qualify by their importance for an exercise of the court's discretionary power of review. Each member of the court votes on each petition for certiorari, as in other actions of the court. The affirmative vote of four justices suffices for the granting of certiorari, since at that stage the question is simply the appropriateness of the case for review. The number of cases that are filed annually in the court exceeds 2,000. Of this total, about five-sixths are disposed of summarily, mainly by the denial of petitions for certiorari.

The cases not thus disposed of are set down for oral argument after the filing of briefs. The time allowed for oral argument is limited, ordinarily to one hour for each side. At a conference of the justices following a week of oral arguments the cases heard during that week are decided, and the responsibility of writing the opinion of the court in each is assigned among the justices by the chief justice (or by the senior associate justice if the chief justice is in the minority in a case). The practice of writing dissenting opinions has been followed since the time of the Marshall court; the first resolute dissenter was Marshall's colleague William Johnson. In this tradition the supreme court stands midway between the British house of lords sitting as a court, where each participating member delivers an opinion, and the judicial committee of the privy council, where only a single opinion is given.

### ROLE IN AMERICAN LIFE

**Changing Contributions and Conflicts.**—Any assessment of the unifying forces in United States society must ascribe an important role to the supreme court. Judicial review of state legislation takes its place in this regard with such physical factors as transportation and communication, and such political factors as national parties and presidential leadership. The chief technical instrument employed by the court in this aspect of its work has been the commerce clause, which conferred power on congress to regulate commerce among the states. This clause has been applied from the time of Marshall to nullify state laws of taxation or regulation that discriminate against or unduly burden interstate commerce. The common national market has thereby been maintained against the grosser demands of local commercial protectionism. The process has been one of accommodation, requiring in each case an appraisal of the state law in the light of local need compared with the inroad on the common market. Marshall's court tended to stress the national imperative, Taney's the concerns of local welfare. At no time in its history, however, has it been possible for the court to avoid making close judgments on a pragmatic basis.

The assertion of national interest that spelled the doom of many state laws has served ultimately to vindicate national power when congress has legislated. Beginning with the Interstate Commerce act of 1887 and the Sherman Anti-Trust act of 1890, congress increasingly took over the regulation of sectors of the economy that previously were regulated ineffectively or not at all because of judicial restraints and practical inhibitions on the states.

A series of decisions, of which the child labour case in 1918 was the most conspicuous, threatened for a time to create a no man's land in which neither the federal nor state governments would have constitutional power to legislate effectively—the federal government denied power because the objective of the law was employment practices, the state governments denied power because the interstate importation of articles of commerce is immune from state prohibition. Not until the overruling of the child labour case in 1941 was the federal power over commerce placed on a firm basis. Subsequently the court sustained far-reaching applications of the commerce power by congress, of which perhaps the most striking was the setting of maximum acreage quotas for the production of wheat, including wheat that is consumed on the farm.

As the commerce clause has been the chief doctrinal source of national power over the economy, the due-process and equal-pro-

tection clauses have been the principal sources of protection of persons and corporations against arbitrary or repressive acts of government. The guarantee of life, liberty and property against deprivation without due process of law, enforceable against the states by virtue of the post-Civil War 14th amendment, has been interpreted by the court to protect against the substance of legislation as well as against arbitrary procedures. Accordingly, during the first third of the 20th century the court invalidated important social and economic measures, including laws of the states setting minimum wages and maximum prices. Liberty of contract was construed in light of a laissez-faire philosophy shared by a dominant majority within the court. Against this paralyzing judicial treatment of experimental legislation Justices Oliver Wendell Holmes and Louis D. Brandeis voiced a current of powerful dissents. Beginning about 1940 the doctrine embodied in these dissents became the law of the land, and thereafter no significant economic legislation was found repugnant to the constitutional guarantees.

The field of civil liberties has had a markedly different history. Not until the 1920s was it established that the rights safeguarded against federal incursion by the first amendment—the rights of freedom of speech, press, assembly and religious exercise—are safeguarded also against action by the states, as part of the liberty guaranteed by the 14th amendment. As the court has become more tolerant of economic controls, it has taken a more stringent view of laws that curtail the first-amendment liberties and the procedural guarantees of the Bill of Rights. Insofar as these changing standards of judicial review have been rationalized, the warrant is that the special concern of the court is with process and structure; that political liberties are at the base of representative self-government; and that if normally the people must look to political processes for the correction of harsh or unwise legislation, the court for that very reason must remain vigilant to strike down those measures that repress the political process itself.

The guarantee of equal protection of the laws in the 14th amendment has had a development similar to the evolution of due process of law. Originally designed for the benefit of the emancipated Negroes, soon utilized as a shield against social legislation, it came at mid-20th century to serve its historic purpose as a barrier to racially discriminatory laws.

In a steady series of cases the court invalidated a variety of restrictions directed at Negroes: exclusion from voting in party primary elections, racial zoning, enforcement of restrictive covenants in real-estate deeds, exclusion from state-maintained universities, and enforced segregation in public schools and on public conveyances.

It is hardly surprising that a tribunal exercising authority of such gravity, delicacy and finality has frequently found itself the object of popular or partisan attack. Given the generality of the great constitutional provisions and the task of applying them to a document to an evolving social, economic and political order, the court cannot escape the responsibility of rendering judgments that provoke dissatisfaction in some quarters and for some time. Whether a judgment is viable will depend on whether it is the court or its critics who have more truly sensed the climate of the age rather than the weather of the day.

A number of the strongest presidents have been pitted at one time or another against the court. Thomas Jefferson and Andrew Jackson found certain of Marshall's opinions decidedly distasteful. Abraham Lincoln, faced with the Dred Scott decision, called for its re-examination, though he was careful to counsel against resistance to the decree itself. Theodore Roosevelt, irked by judicial invalidation of social legislation, urged in 1912 popular revision of judges and popular referenda on judicial decisions. Franklin D. Roosevelt, confronted with a supreme court that had upset a large part of his recovery program, generally by divided decisions, proposed a reorganization of the federal courts. His plan presented to congress in 1937, provided for the appointment of an additional judge for each judge who remained on the bench after having served ten years and reached the age of 70; the maximum size of the supreme court was to be fixed at 15. The plan was

defeated in congress. Meanwhile, however, the supreme court had given clear signs in its intervening decisions that it would take a more hospitable view of the scope of governmental power under the constitution.

**Self-Limitation.**—Cognizant of the risks of ill-advised decisions, the court has developed canons of self-limitation. It will not render advisory opinions, or decide a constitutional question when the case can be disposed of on another ground, or render a constitutional decision broader than required by the facts of the case before it or at the instance of a litigant whose interests are not actually in jeopardy.

A category of "political" questions has been evolved, moreover, which will be left for resolution by other departments of government without judicial review. Some of the most unfortunate decisions of the court have been marked by a disregard of the court's own canons.

Writing in 1928, Charles Evans Hughes characterized three ill-starred decisions as self-inflicted wounds: the Dred Scott case, the first legal tender cases and the income-tax cases. (See Hughes, *The Supreme Court of the United States*, p. 50, 1928.) Each of these was in time uprooted: the first by the Civil War, the second by an overruling decision, the third by the 16th amendment to the constitution. Each was a needlessly precipitate decision: the first because it could have been resolved on a nonconstitutional ground of state law; the second because one member of the court, holding a decisive vote, was on the verge of retirement for disability; the third because the interests of the complainants, corporate stockholders, did not require the relief that the court granted. It is noteworthy that judges who have been deeply sensitive to the demands on constitutional law made by a changing social order—Justice Brandeis most conspicuously—have also been most insistent on the court's observance of its professed canons of self-limitation.

**Important Decisions.**—The Marshall court laid the basis for a federal union capable of effective government. In *McCulloch v. Maryland* (1819), upholding the second Bank of the United States, the court gave a liberal interpretation to the necessary and proper clause of the constitution and thus equipped congress with ancillary powers of great potentiality. A counterpart was the decision in *Gibbons v. Ogden* (1824), holding that a state could not confer a monopoly of interstate steamboat traffic, thus establishing the court as a guardian of the free national market against local commercial self-interest.

The Taney court, although on the whole more sympathetic to the concerns of the states, by no means reversed the current. *Bank of Augusta v. Earle* (1839) established the capacity of a corporation chartered in one state to do business in another; and the *Charles River Bridge Co. v. Warren Bridge Co.* case (1837), while sustaining the power of a state to charter a company in competition with one operating under a prior grant from the state, served to stimulate the development of new forms of interstate transportation. The *Genesee Chief* (1851) extended federal admiralty jurisdiction to inland navigable lakes and rivers, rejecting the English rule that such jurisdiction was confined to tidewaters. Pointing out the divergence between the English and American topography, Taney's opinion is at once a declaration of independence and an avowal that constitutional interpretation should conform to the facts of life.

Unhappily, Taney's reputation was derived too largely from the *Scott v. Sanford* (Dred Scott) case (1857), whose holding that congress lacked power to prohibit slavery in the territories foreclosed one avenue of compromise and helped to precipitate the Civil War. The war itself produced the *Ex parte Milligan* case (1866), a notable landmark in the field of civil liberties, holding that trial of civilians by military commission is unlawful outside the theatre of military operations while the civil courts are capable of functioning.

The post-Civil War amendments to the constitution were constructed in the *Slaughterhouse* cases (1873) and the *Civil Rights* cases (1883) not to have worked a radical transformation in the basic structure of U.S. federalism. The first of these decisions ruled that the privileges and immunities of citizens of the United

States, safeguarded by the 14th amendment, must be narrowly interpreted to include only those privileges peculiar to national citizenship and not such asserted rights as the opportunity to engage in common callings. The second decision established the position that the amendments provide a federal guarantee against racial discrimination by state and not private action.

The due-process clause of the 14th amendment was used in the late 19th and early 20th centuries to strike down economic legislation which did not commend itself to the social philosophy of a majority of the justices. Perhaps the high-water mark was reached in *Lochner v. New York* (1905), invalidating a law which limited the workday of bakers to ten hours: in time the case became less notable for the decision than for the stinging dissent of Justice Holmes. The dissenting position was definitely established as the law of the land in *Nebbia v. New York* (1934), a decision that gave broad scope to economic legislation affecting prices, wages and the hours of labour by renouncing the view that there is a closed category of businesses so affected with a public interest that for them alone is such regulation constitutionally permissible.

The New Deal program of Pres. Franklin D. Roosevelt at first foundered on restrictive constitutional decisions of the court. But the tide turned with the *National Labor Relations Board v. Jones and Laughlin Steel Corp.* case (1937), upholding federal authority over collective bargaining in industries in which work stoppages would affect interstate commerce. The opinion of Chief Justice Hughes was able to draw support from an earlier opinion of his in the *Shreveport* case (1914), where federal authority over intrastate railroad rates was sustained on a showing of their effect upon competitive interstate traffic. Congressional power over industry and agriculture has been validated to an extent ample for legislative purposes. Restraints in the interest of the states have become a matter of congressional discretion rather than constitutional compulsion.

The decision in *Brown v. Board of Education* (1954), holding that separate but equal facilities for Negroes in public schools do not meet the constitutional standard of equal protection of the laws, created the greatest problem of compliance faced by the court since the Marshall period. But the court as an arbitral institution meanwhile won firm acceptance if not always equal understanding.

In *Baker v. Carr* (1962) and succeeding cases the court invalidated, under the equal-protection clause, grossly disproportionate state legislative districts, over the dissent of Justice Frankfurter, who warned that the court was entering a "political thicket." In another series of cases the court applied various provisions of the federal Bill of Rights to state criminal trials, under the due-process guarantee of the 14th amendment; *Mapp v. Ohio* (1961), requiring the exclusion of illegally obtained evidence, is a landmark and symbol. These lines of cases indicate how the court exercises the power of judicial review with increasing intensity to assure more responsive and responsible government.

**Symbolic and Pragmatic Role.**—It has been argued with some force that the functions vested in the supreme court are tolerable only in a country that is agreed on its fundamental premises; that judicial review on the United States model would be impossible where there are deep philosophic cleavages; and that the U.S. practice is a corollary of the pragmatic American spirit. It can be said, however, that the relation is one of interaction. The practice of judicial review, by a reflexive effect, serves to soften the edges of ideological weapons and to promote accommodations on a working basis. The court operates in the context of specific facts; it does not so much choose between absolutes as endeavour to reach a mediating solution; and it holds itself open for reconsideration of doctrine in the light of changed circumstances and fuller experience.

By virtue of the reasoned elaboration of its opinions and the tradition of dissent it serves continually to clarify, refine and test the large philosophic ideals that are written into the constitution, and so to translate them into working principles for a federal union under a rule of law. Beyond its specific contributions, this symbolic and pragmatic function may be regarded as the most

significant role of the supreme court in the life of the nation.

For the role of the United States supreme court in the development of the U.S. federal system and the history of judicial constitutional construction, see AMERICAN LAW AND CONSTITUTION AND CONSTITUTIONAL LAW. See also UNITED STATES (OF AMERICA): History; COURT; and APPEAL.

Important decisions of the court are covered in detail in separate articles on various legal subjects of special interest, for example CIVIL LIBERTIES; CENSORSHIP; INTERSTATE COMMERCE; LABOUR LAW; and PUBLIC UTILITIES: *Regulation in the United States*.

See articles on famous justices, such as BRANDEIS, LOUIS DEMBITZ; CARDOZO, BENJAMIN NATHAN; HOLMES, OLIVER WENDELL; MARSHALL, JOHN; STONE, HARLAN FISKE; and STORY, JOSEPH. See also references under "Supreme Court of the United States, The" in the Index.

**SURABAJA**, capital of East Java Province and the second port (after Jakarta) of Java, Indon., lies at the mouth of the Kali Mas, a branch of the Brantas River, on the Surabaja Strait (which separates Java from Madura Island), 420 mi. (675 km.) ESE of Jakarta. Pop. (1961) 1,007,945. Surabaja has modern houses and offices, hotels, motion-picture theatres, and shops. In contrast to these are the street markets and the crowded downtown districts. The Kali Mas River is canalized, and the canal flows through the centre of the city. From a lookout station at the mouth of the river the railway and road run southward inland, past the old fort (formerly called Fort Prins Hendrik) to the old town, then to the upper town, and beyond that to the suburbs of Gubeng and Wonokromo, where a new residential sector of the city was developed. The naval station is on the south side of the canal, and opposite are the commercial docks; these, destroyed by the Dutch during the Japanese invasion in 1942, have been rebuilt. Notable buildings include a large mosque (1868); the Airlangga University (1954), with faculties of law, medicine, and dental surgery in the city; the Institute of Technology, with university status; and a naval college.

The area around the city is flat and, protected from extremes of climate by Madura Island, is a rich agricultural region. Sugarcane is chiefly grown, other crops including tobacco, maize, and rice. Tapioca, coffee, and cocoa are also produced locally. Cattle are bred, and there is a large fishing fleet.

Surabaja is the largest naval base of Indonesia, as well as a major commercial port and an important industrial centre, with several heavy industries. There are railway locomotive workshops, shipbuilding and ship-repair yards, textile mills, and glass, cigarette, and shoe factories. There is an oil refinery in Wonokromo. The bulk of Java's chief product, sugar, is shipped from Surabaja. Other goods exported include coffee, tobacco, rubber, spices, and petroleum products.

Surabaja is linked with the railway system that connects the eastern and western coasts of Java and is thus in communication with Jakarta, Semarang, Jogjakarta, and the other chief towns of the island. There is shipping communication with the chief ports of the world; Surabaja also lies on the main sea route from Singapore and Jakarta to Australia. From the airport at Tandjungperak, 5 mi. (8 km.) from the city, there are flights to various airports in the island, including Jakarta, and thence to the principal cities in Asia and Europe.

Surabaja was one of the chief centres of resistance to Dutch and British forces during the Indonesian war of independence (1945–49).

**SURAKARTA** (also known as SOLO), a town of Central Java Province, Indon., lies on the Solo River about 260 mi. (420 km.) ESE of Jakarta. Pop. (1961) 367,626. It was the capital

of the protected principality of Surakarta, which constituted a government (status given to major units of administration) of the former Netherlands Indies. The principality, occupied by the Japanese during World War II, was eliminated after independence and incorporated in the Republic of Indonesia. (See JAVA: History.)

The town has broad, tree-lined streets with many modern buildings in addition to the old quarter and busy markets. Traffic is dominated by the *betjak* (tricycle taxi). Notable buildings include the palace of the Susuhunan (1745); the court of Prince Mangku Negoro (1788); the mayor's residence, known as Lodji Gandrung, which accommodates distinguished guests; and the old Dutch fort of Vastenburg (1779), now a garrison headquarters. More modern are the town hall, the telephone exchange, the post office, a rehabilitation centre with its workshop, and an institute for crippled children. Public parks include Sriwedari Park, in the middle of the town, with its zoo, *wajang orang* (drama) performances, motion-picture theatre, and stadium. Long famous as a cultural and educational centre, Surakarta has several private universities, including the Islamic University of Indonesia and faculties of the 17th August 1945 University, including law, agriculture, social sciences, economics, teachers' training, and religion, and there is an academy of art. The Radyapustaka houses the museum and a library.

The town is a market for the surrounding agricultural area, which produces tobacco, sugar, rice, cassava, coconuts, and fruits and vegetables. The making of batik cloth is the main industry, followed by the manufacture of cigarettes, furniture, and textiles; and there is a metal foundry. Local handicrafts include pottery, wood and bone carving, and the making of musical instruments. Surakarta is linked by rail and road with Jakarta, Surabaja, Semarang, and Jogjakarta.

(M. A. J.)

**SURAT**, a city of Gujarat state, India, and the headquarters of the district of the same name, lies near the mouth of the Tapi River, about 160 mi. (260 km.) N of Bombay. Pop. (1961) 288,026. Surat is a city with narrow, winding lanes and densely packed houses. Buildings of historical interest include the Nav-Saiyid Saheb's mosque on the Gopi Tank (now dry) and the nine tombs beside it; the mosque built by Khudawand Khan (1540) and his tomb; the castle (1546); Idrus' Mosque (1639); and Gosari's Temple (1695), destroyed by fire and restored. The city has eight colleges affiliated to Gujarat University. Fine cotton and silk goods are woven in Surat, and its brocades and gold- and silverware are famous. The ancient art of manufacturing superfine muslins, which had died out in the 19th century, was revived in the mid-1950s.

The origin of the town is not clear. It is believed that a Brahmin named Gopi built the Gopi Tank in 1516 and named the area Surajpur or Suryapur, the name being changed to Surat in 1520. Records show, however, that a town existed much earlier. In 1194 Qutb ud-din Aibak, general of Mohammed of Ghor and one of the founders of Muslim rule in India, invaded the Surat region, and in 1347 Mohammed Tughlak, sultan of Delhi, plundered the town. His successor, Firuz Shah Tughlak, built the fort in 1373. In 1514 the Portuguese traveler Duarte Barbosa described Surat as a leading port. The Portuguese burned the town in 1512 and in 1530. The fort was rebuilt by the sultan of Gujarat in 1546.

In 1573 the Mughal emperor Akbar conquered Surat, and for nearly 100 years it enjoyed peace. It became the emporium of India, with a considerable trade in silks, muslins, brocades, and gold with Mocha in Yemen, Basra (Iraq), and Achin (Atjeh) in Sumatra. Its major industries were textile manufacture and shipbuilding. In 1608 the British established their first factory in India at Surat. Surat's gradual decline was due to a number of causes—the raids of the Marathas (1664–84), the rise of Bombay and the ascendancy of the British, the decline of the Mughals after 1707, the loss of the Basra trade in 1776, and internal strife. The British and the Dutch played one party against another, and in 1800 the administration passed to the British. By the mid-19th century Surat was a decayed town of 80,000 inhabitants. Its revival came with the opening of the railways.

SURAT DISTRICT has an area of 2,849 sq.mi. (7,379 sq.km.)

and a population (1961) of 1,313,823. In 1948 the former states of Dharampur, Sachin, and Bansda and the Navsari district of the former Baroda state (with the town of the same name, an old Parsee settlement) were absorbed into the district. Except for a barren coastal stretch of 80 mi. (135 km.), the district is highly cultivated. The chief crops are cotton, millet, pulses, and rice. (V. A. M. J.)

**SURENDRANAGAR**, a town and district of Gujarat state, India. The town, headquarters of the district, lies 60 mi. NE of Rajkot. Pop. (1961) 48,602. It is a trade centre for grain and cotton.

**SURENDRANAGAR DISTRICT**, formerly Zalawad, is one of the six districts that make up most of the Kathiawar (*q.v.*) Peninsula. Area 4,006 sq.mi. (10,376 sq.km.). Pop. (1961) 663,206. It is composed of 21 former princely states, the chief being Limbdi, Lakhtar, Wadhwan, Chotila, and Dhrangadhra. The land is uneven but partly flat. The majority of the population are farmers, the principal crops being cotton and cereals. Industries include manufacture of salt, soap, copper- and brassware, pottery, and textiles. The district is crossed by a network of railways, linking it with Rajkot, Junagadh, and other towns on the peninsula and with the main Western Railway line via Ahmedabad. Main towns besides Surendranagar are Dhrangadhra (pop. [1961] 32,477), Wadhwan (27,104), and Limbdi (21,801). (M. R. P.)

**SURETY**, in law, one who is bound by the same terms as another, known as the principal, for the payment of a debt or the performance of a duty but who, if he satisfies the obligation, is entitled to reimbursement from the principal. In England, the term is often used broadly to describe a person who is liable for the performance of another's obligation and thus includes what is usually meant by guarantor; *i.e.*, one whose liability is contingent on the default of the principal. See FIDELITY AND SURETY BONDS. (E. G. S.)

**SURFACE CHEMISTRY** is concerned with chemical events at the area of contact, called the interface, between immiscible materials of different or like phase; *e.g.*, a liquid with a gas, or a solid with another solid. See ADSORPTION; SURFACE TENSION. See also PHASE EQUILIBRIA.

**SURFACE HARDENING**, a heat treatment of steel in which only the surface is hardened. Other surface-hardening treatments include facing, by fusing a hard metal onto a soft one, and shot peening (*see* BLAST CLEANING AND SHOT PEENING). The conventional quenching of hot steel in water or oil is literally surface hardening; however, it usually hardens not only the surface but some or all of the interior, too, depending on the size of the piece. The phrase "surface hardening" usually implies processes other than merely quenching, such as carburizing, nitriding and induction hardening. The combination of a hard surface and soft interior is of inestimable value in modern engineering practices. Great strength and toughness in the core and extreme surface hardness result in a composite structure capable of withstanding certain kinds of stress to a high degree such as in gears or antifriction bearings. For less exacting requirements, low or moderate core properties and a high surface hardness can be obtained with cheaply fabricated, low-priced steels.

**Carburizing**.—One of the most important surface-hardening processes is carburizing in which steel is held at a high temperature (1,600° F. is common) for a long time (six hours, for instance) in a carbonaceous environment, usually a gas mixture of carbon monoxide and carbon dioxide, with or without hydrocarbons such as methane. This treatment causes carbon to diffuse into the steel to a depth of several thousandths or hundredths of an inch and leaves the carbon content of the surface much higher than that of the core; *e.g.*, 1.5% carbon compared with about .25%. When the carburized steel is quenched it becomes harder and more wear-resistant than similar steel of lower surface carbon content similarly quenched.

**Carbonitriding and Cyaniding**.—Carbonitriding, a variant of carburizing, is the same except that nitrogen as well as carbon diffuses into the steel. The nitrogen comes from ammonia introduced into the furnace atmosphere along with the carbonaceous gas. The cyaniding process gives a similar result; both carbon and

nitrogen are supplied to the steel by diffusion from a liquid cyanide salt (usually potassium cyanide, KCN) in which the steel is immersed at about 1,600° F. Cyanides are violent poisons requiring rigid safety precautions when using the cyanide process of surface hardening.

**Nitriding**.—Another diffusion process producing hard surfaces is nitriding (*q.v.*) in which, by using ammonia without a carbonaceous gas, nitrogen goes into the steel and combines with other elements, principally chromium, already contained in the steel to form nitrides that are extremely hard and wear-resistant without the necessity for quenching the steel. Elimination of the quenching process is an advantage because dimensional changes that occur during quenching are avoided.

**Induction Hardening**.—From about 1935, another process of surface hardening became important—induction hardening. In this process, steel is briefly heated by electrical induction so that only the surface portion has time to get hot. It is immediately cooled or quenched and the portion that was heated above the critical temperature (about 1,500° F.) becomes hard while the rest of the steel which was not heated by the brief flow of induced current remains unaffected. Induction hardening has become common in mass-production industries since World War II because it is a rapid process—heating time per piece may be five seconds or less—and because it often permits the use of a less costly steel than other hardening processes.

**Flame Hardening**.—Flame hardening, like induction hardening, involves no change in the chemical composition of the steel surface. In flame hardening, a high-temperature flame impinges directly on the work for a short time, heating the surface but not the interior of the piece. The depth of hardening is usually  $\frac{1}{8}$  in. or greater. Bulky pieces are often hardened by this method.

**Choice of Methods**.—The choice of a surface-hardening method depends on the design of the part, composition of the steel, type and depth of case needed, permissible distortion, production volume, initial investment and operating cost. Usually a given steel and treatment are compared with another steel-treatment combination. The selection of case depth is also important because a deeper case usually costs appreciably more and may even be undesirable, especially on thin pieces, which become more brittle as the case depth is increased. (T. Ly.)

**SURFACES**. Intuitively, a surface in three-dimensional space (three space) is a two-dimensional set of points selected in a smooth fashion. The simplest examples are planes and spheres. In terms of a Cartesian coordinate system in three space, a plane is the set of points whose coordinates satisfy the equation  $a(x - x_0) + b(y - y_0) + c(z - z_0) = 0$ , the numbers  $a, b, c$  not all zero. The plane passes through the point  $(x_0, y_0, z_0)$  and is perpendicular to the vector  $(a, b, c)$ . A sphere is the set of points whose coordinates satisfy the equation  $(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2 - r^2 = 0$ ; *i.e.*, the locus of a point whose distance from the fixed point  $(x_0, y_0, z_0)$  is  $r$ , a fixed positive number. More generally, if  $f(x, y, z)$  is a smooth function in three space not all whose partial derivatives vanish at any point, the set of points where  $f(x, y, z)$  is zero, *i.e.*, satisfying the equation  $f(x, y, z) = 0$ , constitutes a surface. To see that this point set is two-dimensional, observe that if  $\frac{\partial f}{\partial z}$  does not equal 0 at some point  $(x_0, y_0, z_0)$ , the

equation  $f(x, y, z) = 0$  can be solved for  $z$  as a function  $g$  of  $x$  and  $y$ . Thus the surface in the vicinity of  $(x_0, y_0, z_0)$  can be represented by the equation  $z = g(x, y)$  and consists of the points with coordinates  $(x, y, g(x, y))$ .

This way of representing a surface in the vicinity of a point is quite general. If  $Q$  is a fixed point on the surface and if  $R$  and  $S$  are arbitrary points on the surface, the smoothness assumption guarantees that the plane through  $Q, R$ , and  $S$  approaches a limiting plane through  $Q$  as  $R$  and  $S$  are taken closer and closer to  $Q$ . The limiting plane is called the tangent plane at  $Q$ , and the perpendicular line is called the normal at  $Q$ . If the coordinate system in three space is chosen so that the tangent plane is the  $xy$  plane and the normal line is the  $z$  axis, then distinct points on the surface near  $Q$  project along the  $z$  axis onto distinct points of the tangent plane. If  $g(x, y)$  is the signed distance of a point on the surface to its

projection with coordinates  $x, y$ , then the surface in the vicinity of  $Q$  can be represented by the equation  $z = g(x, y)$ . The  $x$  and  $y$  coordinates of the projection of a point are smooth functions in the vicinity of  $Q$  and serve as a system of coordinates near  $Q$ . The coordinate curves are those on which either  $x$  or  $y$  is constant.

The notion of surface can be freed from its embedding or position in three space. An abstract surface (two-dimensional manifold) is a collection of points together with a family of pairs of functions (see MANIFOLDS). Every point  $Q$  of the manifold has defined in its vicinity a pair of functions that play the role of coordinate functions in this neighbourhood of  $Q$ . The smoothness condition requires that in overlapping neighbourhoods each pair of coordinate functions be expressible as smooth functions of any other pair. The set  $\mathfrak{P}$  of all planes passing through the origin in three space is an example of such an abstract surface. Any such plane  $P$  in  $\mathfrak{P}$  can be represented by the equation  $ax + by + cz = 0$ , so that the three numbers  $(a, b, c)$  not all zero and depending on  $P$  characterize this plane up to a nonzero scale factor. If, say,  $a \neq 0$  for a fixed plane  $P$ , nearby planes will also have  $a \neq 0$ . The functions  $b/a, c/a$  are coordinate functions in the vicinity of  $P$  but are not well defined for all of  $\mathfrak{P}$  since  $a = 0$  for the plane  $z = 0$ . Nevertheless one of the pair  $b/a, c/a$  or  $c/b, a/b$  or  $a/c, b/c$  will serve as coordinate functions near any element of  $\mathfrak{P}$ . This particular surface is called projective space and is not realizable as a surface in three space.

Surfaces can be considered from several points of view. Depending on how much additional structure is put on the surface, one studies their topological, metric, conformal, or algebraic properties. Two abstract surfaces are topologically equivalent if a one-to-one correspondence can be found between the points of each surface in such a way that a sequence of points  $Q_n$  gets closer and closer to a point  $Q$  of the first surface if and only if the corresponding points  $Q'_n$  get closer to  $Q'$  in the second surface. Intuitively such a correspondence between surfaces need not preserve any distances imposed on the surfaces. It allows stretching but no tearing. As a result, this aspect of surface theory is called rubber-sheet geometry (see fig. 1). Compact, orientable surfaces

FIG. 1.—EACH TORUS IS TOPOLOGICALLY EQUIVALENT TO THE OTHER

are easily classified. A surface is compact if every infinite sequence of points of the surface has a subsequence that comes closer and closer (converges) to a point of the surface. A surface is orientable if the family of coordinate functions can be so chosen that on overlapping neighbourhoods the Jacobian (determinant) expressing one pair as a function of the other is positive. A long strip of paper with the ends joined after a half twist is a simple example of a surface that is not orientable; the projective space described previously is another. Besides the sphere, the simplest example of a compact surface is a torus; e.g., a rubber tire. It can be realized in three space by revolving the circle  $x^2 + y^2 = 1$  in the  $xy$  plane about the line  $x = 2$ . It is topologically equivalent to putting a handle on a sphere; e.g., cutting two circular holes in a spherical ball and connecting them by a tube. The most general compact, orientable surface is topologically equivalent to a sphere with  $n$  handles (fig. 2). Noncompact surfaces are harder to classify; however, those for which loops can be continuously deformed to a point are topologically equivalent to a plane (see TOPOLOGY, ALGEBRAIC; TOPOLOGY, GENERAL).

The metric or Riemannian structure imposed on a surface involves the notion of the distance between two points of a surface. For a surface in three space, the distance between two points  $Q$

ADAPTED FROM R. COURANT AND H. E. ROBBINS, "WHAT IS MATHEMATICS?", 1941, OXFORD UNIVERSITY PRESS

FIG. 2.—TOPOLOGICALLY EQUIVALENT FORMS OF A SPHERE WITH TWO HANDLES

and  $R$  is the greatest lower bound of the arc lengths of all curves on the surface beginning at  $Q$  and ending at  $R$ . Since the arc length of a curve with given parameters is the integral of the lengths of its tangent vectors, the lengths of vectors tangent to the surface determine the distance between points. The function that assigns to each tangent vector the square of its length is called the first fundamental form or Riemannian metric of the surface (see RIEMANNIAN GEOMETRY). The Riemannian metric not only determines distance, length of tangent vectors, and the angle between vectors but gives other geometric invariants of the surface. The notion of parallel transport of a vector along a curve can be defined geometrically as a field of vectors tangent to the surface at each point of a curve with derivatives in three space that are always normal to the surface. Geodesics are curves on the surface with tangent vectors that are parallel transports of themselves. They are also curves whose small arcs are curves of shortest length between their extremities. The Gaussian curvature at a point of the surface is the limit of the amount of turning a vector undergoes when it is transported around smaller and smaller rectangles. The geometric entities definable in terms of the first fundamental form are called intrinsic invariants of the surface.

Each point of an abstract surface also has a tangent space: the space of directional derivatives of the family of functions on the surface smooth near the point. If lengths and angles between vectors are imposed on each such tangent space, the abstract surface gains a Riemannian metric, and the geometric notions of the previous paragraph are valid. Two surfaces with Riemannian structures are isometric if there is a smooth one-to-one correspondence of their points preserving their Riemannian metric. An abstract Riemannian structure is more general than one in three space. For example, a torus can be endowed with a metric that has zero Gaussian curvature at every point, while a torus in three space has a first fundamental form giving a Gaussian curvature not identically zero. However, every surface with Riemannian metric is embeddable in a Euclidean space of sufficiently high dimension in such a way that its metric is the one it inherits from the embedding.

Aside from the intrinsic invariants, an additional measurement is needed to describe how a surface lies in three space. For example, a twisted sheet of paper can be straightened into a flat sheet without changing distances; thus the twisted form is metrically equivalent to a portion of a plane. Yet the position of the twisted sheet in three space is entirely different from that of a plane. This difference is completely described by the second fundamental form. Two isometric surfaces with the same second fundamental form at corresponding points differ only by a motion of three space that is a translation followed by a rotation. The second fundamental form measures the rate at which the normal direction changes at a point moving about the surface. It is the function of the tangent space whose value on a vector  $v$  is the scalar product of  $v$  with  $N_v$  (the rate of change in the direction of  $v$  of the unit normal).  $N_v$  lies in the tangent space and the transformation sending  $v$  into  $N_v$  is a symmetric transformation that becomes a  $2 \times 2$  symmetric matrix  $(q_{ij})$  in the presence of a coordinate system. The determinant of  $S$  turns out to be the Gaussian curvature so that the second fundamental form gives a nonintrinsic characterization of this curvature. If the surface is of the form  $z = g(x, y)$  in the vicinity of the origin with the  $xy$  plane as tangent plane as previously described, then the matrix of  $S$  is

$$\begin{pmatrix} \frac{\partial^2 g}{\partial x^2} & \frac{\partial^2 g}{\partial x \partial y} \\ \frac{\partial^2 g}{\partial y \partial x} & \frac{\partial^2 g}{\partial y^2} \end{pmatrix}$$

As a result, if the Gaussian curvature is positive, the surface lies on one side of the tangent plane; at such a point the surface is elliptic. If the Gaussian curvature is negative, part of the surface is on one side, part on the other side of the tangent plane, and the surface has a saddle in the vicinity of the origin; such a point is called hyperbolic (fig. 3). At a parabolic point the Gaussian curvature is zero. One half the trace of  $S$  is called the mean curvature of the surface at the point; the eigenvalues of  $S$  are called the principal curvatures; and the eigenvectors of  $S$  are called the directions of principal curvature (see DIFFERENTIAL EQUATIONS, PARTIAL; OPERATORS, THEORY OF). A line of curvature is a curve on the surface with tangent vectors that lie in a direction of principal curvature. If the eigenvalues of  $S$  are distinct at a point, the lines of curvature form a two-parameter orthogonal family of curves in the vicinity of this point. An umbilical point is one where the two eigenvalues of  $S$  coincide.

FIG. 3.—SADDLEPOINT (AT P)

The second fundamental form also measures the amount of turning a curve on the surface does in the normal direction. The curvature vector at a point of a curve in three space is the derivative of its tangent vectors. If the curve lies on a surface, its curvature vector is the sum of a tangent vector (the geodesic curvature vector) and a normal vector (the normal curvature vector). Two curves on the surface with the same tangent vector  $v$  have the same normal curvature vector. The length of the normal curvature vector is the ratio of the second fundamental form over the first fundamental form evaluated at  $v$  and is called the normal curvature. The extreme values of the normal curvatures at a point occur at the principal curvature directions.

Of special interest are surfaces in three space with constant Gaussian curvature. If the curvature is zero, the surface is called developable, for any small portion of such a surface is isometric (can be developed onto) to a portion of a plane. Locally a developable surface consists of a one-parameter family of straight lines with the property that the tangent planes along one line coincide, so that the collection of tangent planes forms only a one-parameter family. An example of a developable surface is the tangent developable consisting of the family of tangent lines to a smooth curve (see CURVES). Developable surfaces are special cases of ruled surfaces; i.e., those made up of straight lines (see MATHEMATICAL MODELS). If the curvature is a constant positive number  $a^2$ , small regions of the surface are isometric to a region on a sphere in three space of radius  $\frac{1}{a}$ . Nevertheless, such a surface in three space need not be on a sphere. If, however, the surface is compact, then it is in fact a sphere of radius  $\frac{1}{a}$ . It is said that the

FIG. 4.—PSEUDOSPHERE

surfaces in three space with curvature  $-a^2$  are not all infinitely extendable. Some must approach a boundary or singularity of the surface. On the pseudosphere this happens as  $x$  approaches  $a$ .

The surfaces of constant curvature form models of non-Euclidean geometries, geometries in which Euclid's fifth or parallel postulate does not hold (see GEOMETRY: Non-Euclidean Geometry). On a surface, interpret straight line to mean geodesic, angle between intersecting lines as the angle between tangent vectors of intersecting geodesics, and parallel lines as geodesics that do not meet. Then a sphere with opposite points identified is an example of an elliptic non-Euclidean geometry in which every pair of lines meet; i.e., every pair of geodesics (great circles) meet. A hyperbolic geometry is one in which there are many lines through a given point parallel to a given line. Examples of such a geometry stem from surfaces of constant negative curvature. A simple model is the interior of the circle in the plane of radius one. A metric structure can be placed on this set in such a way that the curvature is constantly  $-1$  and geodesics are arcs of circles perpendicular to the given circle. Since there are many such arcs through a given point that do not meet a given arc, this space gives a hyperbolic geometry (fig. 5).

FIG. 5.—POINCARÉ MODEL OF HYPERBOLIC GEOMETRY

The conformal structure of a surface is described in terms of the angle between vectors, ignoring vector lengths. Consideration of a conformal structure on a surface originated in the theory of analytic functions of a complex variable (see ANALYSIS, COMPLEX). If  $f(z)$  is an analytic function in the complex plane, its differential sends tangent vectors at  $z$  into tangent vectors at  $f(z)$  so that the angle between corresponding pairs of vectors is the same; lengths of corresponding vectors need not be the same. Suppose  $f(z)$  is a multiple-valued function analytic on a portion of the complex plane;  $\sqrt{z}$ , for example. To find the largest domain in which it is analytic, in fact, to construct a set on which it is single valued, start with a single-valued branch of the function in a region of the plane and analytically extend or continue the function along curves as far as possible. When a region is reached in which the function has already been defined, this region is not identified with the original one unless the new function obtained agrees with the old function. In this way a surface (the Riemann surface) is constructed of the function  $f(z)$  on which an extension of  $f(z)$  is single valued. Since every sufficiently small portion of this surface is the same as a region in the plane, the complex coordinate  $z$  is well defined on this portion. A function on this Riemann surface is analytic if it is an analytic function in every small region of the complex coordinate  $z$ . The Riemann surface of  $f(z)$  is hard to visualize in

three space and in general is not a surface in three space, since the analytic continuation process gives a surface that may intersect itself in three space. The Riemann surface of  $\sqrt{z}$ , for example, is constructed by taking two planes, cutting each along the positive axis, and pasting the upper edge of each with the bottom edge of the other.

A complex coordinate system can be introduced in the vicinity of any point of a surface with Riemannian metric. First, surface coordinate functions are found in which the coordinate curves are orthogonal. If  $u$  and  $v$  are such isothermal coordinates the complex coordinate is  $z = u + iv$ . On overlapping regions the change from one complex coordinate to another is analytic. The surface with these complex coordinate systems is called a Riemann surface or complex manifold. Two metrics on a surface give the same Riemann surface if their first fundamental forms differ only by a scale factor possibly varying from point to point. Two Riemann surfaces are conformal or analytically equivalent if there is a one-to-one correspondence between them that preserves angles. For example, the sphere with the north pole deleted is conformal with the plane. A particular conformal correspondence of the sphere with the plane useful in making flat maps of the earth is the Mercator projection (see MAP).

An algebraic surface in three space is one whose equation is  $f(x, y, z) = 0$ , with  $f(x, y, z)$  a polynomial (q.v.) in  $x, y, z$ . The order of the surface is the degree of the polynomial equation. If the surface is of the first order, it is a plane. If the surface is of order two, it is called a quadric surface. By rotating the surface, its equation can be put in the form

$$Ax^2 + By^2 + Cz^2 + Dx + Ey + Fz = G$$

If  $A, B, C$  are all not zero, the equation can generally be simplified to the form  $ax^2 + by^2 + cz^2 = 1$ . This surface is called an ellipsoid (q.v.) if  $a, b$ , and  $c$  are positive. Its Gaussian curvature is positive at every point. If one of the coefficients is negative, the surface is a hyperboloid (q.v.) of one sheet (fig. 6); if two of the coefficients are negative, the surface is a hyperboloid of two sheets. A hyperboloid of one sheet can be visualized by rotating the hyperbola  $x^2 - y^2 = 1$  about the  $y$  axis. The surface has a saddle point at  $x = 1, y = z = 0$ . If the hyperbola is rotated about the  $x$ -axis, it generates a hyperboloid of two sheets. If  $A, B, C$  are possibly zero, cylinders, cones, interesting planes, and elliptic or hyperbolic paraboloids may be produced (see PARABOLOID). Examples of the latter are  $z = x^2 + y^2$  and  $z = x^2 - y^2$ , respectively. Through every point of a quadric pass two straight lines (possibly imaginary) lying on the surface. A cubic surface is one of order three. Its most remarkable property is that 27 lines lie on it, each one meeting 10 others. In general, a surface of order four or more contains no straight lines.

**SURFACE TENSION**, a force that gives liquid surfaces filmlike characteristics. Thus a thin razor blade or a water beetle can ride the surface of water without breaking through. The tension is explained as resulting from an attraction between molecules of the liquid. The following examples of other surface phenomena are explained in a similar way.

The surface of water (or other liquid) in a tank is not perfectly level but becomes curved where the liquid comes in contact with the wall of the tank.

If a tube with a very narrow bore (see CAPILLARY TUBE) is placed with one end in the water, the liquid rises above the level of the outer surface. The rise is greater the smaller the diameter of the bore. The rise of oil through a wick is a phenomenon of the same kind.

If a small quantity of mercury is poured on a horizontal plate, it forms a drop. Very small drops are nearly spherical; larger ones tend to have flat tops and rounded edges.

A drop of oil placed on a clean water surface spreads rapidly to form a very thin film. The thinness of the film can be judged from the size of the area covered by even a small drop. Soap bubbles and froth are other familiar examples of thin films.

Camphor fragments on a clean surface of water show rapidly changing motion. A minute quantity of oil placed on the surface brings them almost instantaneously to rest.

Such phenomena and others (e.g., see ADSORPTION), all arising at surfaces separating one medium from another, can be studied under one heading. The forces that come into play are known as surface forces. The rise in capillary tubes is called capillary action. This name, though often applied in other cases, is hardly applicable except to the case of narrow tubes; while the term surface action is applicable in all. The forces involved act between neighbouring parts of substances; they also produce the effects of cohesion.

Sir Isaac Newton in the third edition of his *Opticks* wrote: "The parts of all homogeneous hard Bodies, which fully touch one another, stick together very strongly . . . I . . . infer from their Cohesion that their Particles attract one another by some force which in immediate Contact is exceeding strong, at small distances performs the chymical Operations above mention'd, and reaches not far from the particles with any sensible Effect. . . . There are therefore Agents in Nature able to make the Particles of Bodies stick together by very strong Attractions. And it is the Business of experimental Philosophy to find them out."

These forces are distinguished from those of gravity which can act over very great distances (see FORCE). Cohesion acts to any measurable extent only over minute distances. If a stick of chalk is broken, the two parts no longer stick together; the neighbouring particles are still so far apart as to exert no sensible attraction. High pressure is needed to bring them close enough for this.

In some applications it is desirable to reduce the forces of cohesion; for example, great sums of money and considerable effort are devoted to the preparation of materials that act to reduce the surface tension of water. Such additives substantially increase the effectiveness of laundering, facilitate chemical reactions in manufacturing, and allow efficient recovery of petroleum from shale deposits (see DETERGENTS AND WETTING AGENTS).

**History.**—(The following historical summary is taken from James Clerk Maxwell's classical article in the 9th ed. of *Encyclopædia Britannica*, as modified by the 3rd Lord Rayleigh in the 10th ed.) According to J. C. Poggendorff (*Pogg. Ann.* ci. p. 551, 10th ed.) Leonardo da Vinci must be considered as the discoverer of capillary phenomena, but the first accurate observations of the capillary action of tubes and glass plates were made by Francis Haukebee (*Physico-Mechanical Experiments*, London, 1709, pp. 139–169) and *Phil. Trans.* 1711 and 1712), who ascribed the action to an attraction between the glass and the liquid. He observed that the effect was the same in thick tubes as in thin, and concluded that only those particles of the glass which are very near the surface have any influence on the phenomenon. Dr. James Jurin (*Phil. Trans.*, 1718, p. 739, and 1719, p. 1083) showed that the height at which the liquid is suspended depends on the section of the tube at the position of the meniscus, and is independent of the form of the lower part. Sir Isaac Newton devoted the 31st query in the last edition of his *Opticks* to molecular forces, and instanced several examples of the cohesion of liquids, such as the suspension of mercury in a barometer tube at more than double the height at which it usually stands. This arises from its adhesion to the tube, and the upper part of the mercury sustains a consid-

FIG. 6.—HYPERBOLOID OF ONE SHEET

erable tension, or negative pressure, without the separation of its parts. He considered the capillary phenomena to be of the same kind, but his explanation is not sufficiently explicit with respect to the nature and the limits of the action of the attractive force.

It is to be observed that, while these early speculators ascribe the phenomena to attraction, they do not distinctly assert that this attraction is sensible only at insensible distances, and that for all distances which we can directly measure the force is altogether insensible. The idea of such forces, however, had been distinctly formed by Newton, who gave the first example of the calculation of their effect in his theorem on the alteration of the path of a light-corpuscle when it enters or leaves a dense body.

Alexis Claude Clairaut (*Théorie de la figure de la terre*, Paris, 1808, pp. 105, 128) appears to have been the first to show the necessity of taking account of the attraction between the parts of the fluid itself in order to explain the phenomena. He did not, however, recognize the fact that the distance at which the attraction is sensible is not only small but altogether insensible. J. A. von Segner (*Comment. Soc. Reg. Götting. i. p. 301*) introduced the very important idea of the surface tension of liquids, which he ascribed to attractive forces, the sphere of whose action is so small that it cannot be perceived ("ut nullo adhuc sensu percipi poterit").

In 1756 J. G. Leidenfrost (*De aquae communis nonnullis qualitatibus tractatus*, Duisburg) showed that a soap bubble tends to contract, so that if the tube with which it was blown is left open the bubble will diminish in size and will expel through the tube the air which it contains.

In 1787 Gaspard Monge (*Mémoires de l'Acad. des Sciences*, 1787, p. 506) asserted that "by supposing the adherence of the particles of a fluid to have a sensible effect only at the surface itself and in the direction of the surface it would be easy to determine the curvature of the surfaces of fluids in the neighbourhood of the solid boundaries which contain them; that these surfaces would be *lenticulae* of which the tension, constant in all directions, would be everywhere equal to the adherence of two particles, and the phenomena of capillary tubes would then present nothing which could not be determined by analysis." He applied this principle of surface tension to the explanation of the apparent attractions and repulsions between bodies floating on a liquid.

In 1802 John Leslie (*Phil. Mag.*, 1802, vol. xiv, p. 193) gave the first modern explanation of the rise of a liquid in a tube by considering the effect of the attraction of the solid on the very thin stratum of the liquid in contact with it. He did not, like the earlier speculators, suppose this attraction to act in an upward direction so as to support the fluid directly. He showed that the attraction is everywhere normal to the surface of the solid. The direct effect of the attraction is to increase the pressure of the stratum of the fluid in contact with the solid, so as to make it greater than the pressure within the fluid.

In 1804 Thomas Young (essay on the "Cohesion of Fluids," *Phil. Trans.*, 1805, p. 65) founded the theory of capillary phenomena on the principle of surface tension. He also observed the constancy of the angle of contact of a liquid surface with a solid, and showed how from these two principles to deduce the phenomena of capillary action. His essay contains the solution of a great number of cases, including most of those afterwards solved by Laplace, but his methods of demonstration, though always precise, and often extremely elegant, are sometimes rendered obscure by his scrupulous avoidance of mathematical symbols. Having applied the secondary principle of surface tension to the various particular cases of capillary action, Young proceeded to deduce surface tension from underlying principles. He supposed the particles to act on one another with two different kinds of force, one of which, the attractive forces of cohesion, extends to particles at a greater distance than those to which the repulsive force is confined. He further supposed that the attractive force is constant throughout the minute distance to which it extends, but that the repulsive force increases rapidly as the distance diminishes. He thus showed that, at a curved part of the surface, a superficial particle would be urged towards the centre of curvature of the surface, and he gave reasons for concluding that this

force is proportional to the sum of the curvatures of the surface in two normal planes at right angles to each other.

The subject was next taken up by Pierre Simon Laplace (*Mécanique céleste*, supplement to the tenth book, pub. in 1806). His results are in many respects identical with those of Young, but his methods of arriving at them are very different, being conducted entirely by mathematical calculations. For those who wish to study the molecular constitution of bodies it is necessary to study the effect of forces which are sensible only at insensible distances; and Laplace has furnished us with an example of the method of this study which has never been surpassed. He found for the pressure  $p$  at a point in the interior of the fluid an expression of the form

$$p = K + \frac{1}{2}H(1/R + 1/R')$$

where  $K$  is a constant pressure, probably very large, which, however, does not influence capillary phenomena, and therefore cannot be determined from observation of such phenomena;  $H$  is another constant on which all capillary phenomena depend; and  $R$  and  $R'$  are the radii of curvature of any two normal sections of the surface at right angles to each other.

The next great step in the treatment of the subject was made by J. C. F. Gauss (*Principia generalia Theoriae Figuræ Fluidorum in statu Aequilibrî*, Göttingen, 1830, or *Werke*, v. 29, Göttingen, 1867). The principle which he adopted is that of virtual velocities, a principle which under his hands was gradually transforming itself into what is now known as the principle of the conservation of energy. Instead of calculating the direction and magnitude of the resultant force on each particle arising from the action of neighbouring particles, he formed a single expression which is the aggregate of all the potentials arising from the mutual action between pairs of particles. This expression has been called the force function. With its sign reversed it is now called the potential energy of the system. It consists of three parts, the first depending on the action of gravity, the second on the mutual action between the particles of the fluid, and the third on the interaction of the particles of the fluid and the particles of a solid or fluid in contact with it.

The condition of equilibrium is that this expression (which we may for the sake of distinctness call the potential energy) shall be a minimum. This condition when worked out gives not only the equation of the free surface in the form already established by Laplace, but the conditions of the angle of contact of this surface with the surface of a solid.

In 1831 Siméon Denis Poisson published his *Nouvelle Théorie de l'action capillaire*. He maintained that there is a rapid variation of density near the surface of a liquid, and he gave very strong reasons, which have been only strengthened by subsequent discoveries, for believing that this is the case.

The result, however, of Poisson's investigation is practically equivalent to that already obtained by Laplace. In both theories the equation of the liquid surface is the same, involving a constant  $H$  which can be determined only by experiment. The only difference is in the manner in which this quantity  $H$  depends on the law of the molecular forces and the law of density near the surface of the fluid, and as these laws are unknown to us we cannot obtain any test to discriminate between the two theories.

We have now described the principal forms of the theory of capillary action during its earlier development. In more recent times the method of Gauss has been modified so as to take account of the variation of density near the surface, and its language has been translated in terms of the modern doctrine of the conservation of energy. See Enrico Betti, *Teoria della Capillarità: Nuovo Cimento* (1867); a memoir by M. Stahl, "Ueber einige Punkte in der Theorie der Capillarscheinungen," *Pogg. Ann.* cxxxix. p. 239 (1870); and J. D. Van der Waals' *Over de Continuïteit van den Gas- en Vloeistofstand*. A good account of the subject from a mathematical point of view will be found in James Challis's "Report on the Theory of Capillary Attraction," *Brit. Assn. Report*, iv. p. 235 (1834).

J. A. F. Plateau (*Statique expérimentale et théorique des liquides*, 1873), who made elaborate study of the phenomena of

surface tension, adopted the following method of getting rid of the effects of gravity. He formed a mixture of alcohol and water of the same density as olive oil, and then introduced a quantity of oil into the mixture. It assumes the form of a sphere under the action of surface tension alone. He then, by means of rings of iron wire, discs, and other contrivances, altered the form of certain parts of the surface of the oil. The free portions of the surface then assume new forms depending on the equilibrium of surface tension. In this way he produced a great many of the forms of equilibrium of a liquid under the action of surface tension alone, and compared them with the results of mathematical investigation. The debt science owes to Plateau is not diminished by the fact that, while investigating these beautiful phenomena, he never saw them, having lost his sight about 1840.

G. L. van der Mensbrugghe (*Mém. de l'Acad. Roy. de Belgique*, xxxvii., 1873) devised a great number of beautiful illustrations of the phenomena of surface tension, and showed their connection with the experiments of Charles Tomlinson on the figures formed by oils dropped on the clean surface of water.

Athanase Dupré in his 5th, 6th, and 7th memoirs on the mechanical theory of heat (*Ann. de Chimie et de Physique*, 1866-68) applied the principles of thermodynamics to capillary phenomena, and the experiments of his son Paul were exceedingly ingenious and well devised, tracing the influence of surface tension in a great number of very different circumstances, and deducing from independent methods the numerical value of the surface tension. The experimental evidence which Dupré obtained bearing on the molecular structure of liquids must be very valuable, even if our present opinions on this subject should turn out to require modification.

### GENERAL THEORY OF CAPILLARY ACTION

It is found by experiment that the forces between molecules to which cohesion is due only act perceptibly across very short distances. If we regard the forces between two particles as acting according to a law depending only upon their positions it must vary inversely as the distance according to a higher power than that of the inverse square which is obeyed by gravitation. The experiments of G. H. Quincke and others show that the extreme range through which sensible effect is produced by them is certainly much less than a thousandth of a centimetre and it is probably less than one millionth.

In order to illustrate the important bearing of this limitation in range, consider a molecule *A* well within a substance (fig. 1).

FIG. 1

A sphere of a thousandth of a centimetre radius may be drawn round it and the molecules outside this sphere will have no sensible influence on *A*. Those within the sphere attract *A* but in the case of a homogeneous isotropic body their pulls will be uniformly distributed and the resultant force on *A* will be zero. There will, however, be a pressure throughout the sphere due to the attraction; each spherical layer, being attracted, will compress the particles lying inside it. But if we consider a particle *B* very near the surface—nearer in fact than the range of action—the state of things will be found to be different. There will be more particles pulling *B* downwards than upwards so that all such particles as *B* will undergo a resultant force downwards. There will also be a pressure at *B* but its value is less the nearer *B* is to the surface. There is, therefore, a thin, indefinitely bounded layer near the surface which is in a different condition from the main body of

the substance. Many of the properties will be different in this surface layer from elsewhere. For example, corresponding to the different pressure, the density will be different. Since work is done in producing compression the potential energy will differ in the two regions. In the main body it can be written

$$\int \chi \rho \rho_0 dV = \chi_0 \rho_0 V_0$$

where  $V$  = volume,  $\rho$  density, and  $\chi$  the potential energy per unit mass; in the film, owing to its minute thickness  $\epsilon$  (which we divide up into still thinner layers  $d\epsilon$ ), and surface (area)  $S$  we write total mass  $M$  as

$$M = V\rho_0 - S \int_0^\epsilon (\rho_0 - \rho) d\epsilon$$

while the total potential energy  $E$  (in terms of  $\chi$  its value per unit mass) is written

$$E = \int \chi \rho dV$$

or

$$E = V\chi_0\rho_0 - S \int_0^\epsilon (\chi_0\rho_0 - \chi\rho) d\epsilon$$

Multiplying the total mass  $M$  by  $\chi_0$  and subtracting from the last expression

$$E - M\chi_0 = S \int_0^\epsilon (\chi - \chi_0)\rho d\epsilon$$

The right-hand side is therefore an expression for that part of the energy which depends upon the existence of a surface  $S$ . The integral which multiplies it is the constant (or rather, factor) known as the surface tension. This integral is a measure of the work done in increasing the area of the surface. It must be carefully distinguished from the corresponding increase in the total energy because heat energy is drawn in simultaneously if the change takes place at constant temperature.

By the principles of energy the potential energy (at constant temperature) tends to a minimum; in other words, any change that takes place spontaneously involves a diminution of this energy. Hence whenever the surface tension is positive there will be a tendency for the surface to decrease, and the diminution will in fact take place unless it is resisted by other forces. This diminution takes place not by a contraction of the liquid but by a passage of the surface molecules into the body of the liquid. The properties of the body are not changed thereby. In this respect the phenomenon is quite different from the case of a stretched india-rubber film. For the liquid the surface tension remains constant during the contraction of the surface area; in the case of the stretched india-rubber it diminishes with the contraction.

We may express it otherwise by saying that if an imaginary straight line be drawn anywhere in the surface, when equilibrium exists there must be a force acting across the line in such a direction as to prevent further contraction of area. It may be shown that this force per unit length of line is numerically the same as the surface tension as defined above.

FIG. 2

The surface tension of a liquid film may be illustrated with a piece of sheet metal cut in the form  $AA'$  (fig. 2). A very fine slip of metal is laid on it in the position  $BB'$  and the whole is dipped into a solution of soap. When it is taken out the rectangle  $AA'CC'$  is filled by a liquid film. This film tends to contract on itself and the loose strip of metal will, if let go, be drawn toward  $AA'$ . If  $S$  is the area of one face of the film the potential energy is  $\sigma S$ . If  $AA' = b$  and  $AC = a$  it is equal to  $\sigma ab$ . Hence if  $F$  is the force by which the slip is pulled toward  $AA'$ ,  $F = \frac{d}{db}(\sigma ab) = \sigma a$

so that the force per unit length for one face is  $\sigma$ . Hence  $\sigma$  is either the force per unit length or the potential energy per unit area.

It must be added that we have only considered one of the two faces and the force due to it. There is an equal force on the strip due to the second surface so that the total force is twice as great as the value taken. But the total area is twice as great also so that the conclusion remains unchanged.

There are other ways of illustrating the existence of the tension. Form a film as before but in a fixed frame. Tie a short length of fine unspun silk to form a flexible ring. If it is placed carefully on the film it usually takes an irregular shape. If the film inside the ring is destroyed by piercing it with a hot wire the silk opens into a circular form, this being the form that minimizes the surrounding surface for a given length of thread. Again, a small drop of mercury or a falling raindrop is practically spherical—the sphere being the form with the smallest area for a given volume. A large drop fails to be spherical because gravitational forces are then strong enough to compete successfully with surface forces. Sometimes a difficulty is felt in connection with the assertion that the surface tension is constant. Take a film such as we considered and place it vertically. The upward force on  $AA' = 2\sigma a$  for the two faces, the downward force at the level  $CC'$  is also  $2\sigma a$ . The remaining force on the portion of the film between these lines is its weight. Hence the resultant force on the mass of the film is its weight and its acceleration should therefore be that of a freely falling body. Yet whatever may be found for a pure substance, it does not hold in general that the tension is the same at all parts of a large area. In the case of a soap film some adjustment automatically occurs (either by alteration of concentration or otherwise) which makes the upper tension a little greater than the lower. This produces a durable film that otherwise would fall to pieces.

**Theory of Cohesion.**—Cohesion was once explained by assuming forces between elements (*i.e.*, infinitesimal volumes) of matter; it was supposed that the substance of a body is distributed continuously instead of being partitioned into molecules. Such was the mode in which Laplace regarded it. The reasoning ran as follows:

Let the force between two elementary volumes be supposed proportional to the product of the volumes and inversely as the  $n$ th power of their distances apart. The force required is that across unit area drawn anywhere well inside the body arising from the volumes on each side of it.

Take a lamina of thickness  $dy$  (fig. 3). The force on an elementary volume  $v$  due to a zone of radius  $x$  and width  $dx$  is  $\frac{2\pi x dx}{r^n} \cdot \frac{a}{r} dy$  since the tangential components will cancel each other. Hence the whole lamina attracts the element with a force

$$2\pi va \int_a^\infty \frac{xdx}{r^{n+1}} dy = 2\pi va \int_0^\infty \frac{dr}{r^n} dy$$

This becomes  $\frac{2\pi va}{(n-1)a^{n-1}} dy$  or  $\frac{2\pi v}{(n-1)a^{n-2}} dy$  since we assume the forces to vanish at infinity.

Let  $v$  be an element in a parallel lamina of thickness  $da$ . Then the total force per unit area on such a lamina is obtained by putting  $v = da$ . Hence we find the force on a semi-infinite solid above lamina II due to lamina I shown in fig. 3 by integrating from 0 to  $\infty$ ; that is

$$\begin{aligned} \text{Force on semisolid (per unit area)} &= \frac{2\pi dy}{n-1} \int_0^\infty \frac{da}{a^{n-2}} \\ &= \frac{2\pi}{(n-1)(n-3)} \left| \frac{1}{a^{n-3}} \right|_0^\infty \end{aligned}$$

The force (per unit area) on such a semi-infinite body due to a semi-infinite body in contact with it is obtained by integrating

with respect to  $y$  from  $y = 0$  to per unit area and is given by

$$K_0 = \frac{2\pi}{(n-1)(n-3)} \left( \frac{1}{s^{n-4}} \right)$$

The unit of force used is that between two by unit distance.

Lord Rayleigh noted: "The pressure will whatever  $n$  may be. If  $n = 4$  be negative the infinitely distant parts contributes to the result; with  $n = 4$  be positive the parts in immediate contiguity act with the power. For the transition case, discussed by W. Sutherland (*Phil. Mag.* xxiv. p. 113, 1887) of  $n = 4$ ,  $K$  is also infinite. . . . It seems therefore that nothing satisfactory can be arrived at under this head."

It was later realized that to treat the body as a continuum is bound to give erroneous results; and modern explanations are based on the notion of discrete units (molecules). If we assume the existence of attractions depending on the distance between the centres of the molecules it is at the same time necessary to recognize that the two halves of the body can never approach to absolute contact. The lower limit in the last integration should be the least distance of separation between the lines of centres of contiguous layers. This will be a magnitude comparable with the molecular diameter  $s$ . The value we seek then becomes

$$K_0 = \frac{2\pi}{(n-1)(n-3)(n-4)} \cdot \frac{1}{s^{n-4}}$$

There is now no objection on the above grounds to the power law provided that  $n > 4$ .

There can be no doubt that if the amount of matter compressed into unit volume (*i.e.*, the density  $\rho$ ) be increased the value of the intrinsic pressure would be increased. Moreover, a factor  $\Gamma$  (akin to the gravitation constant) is also needed if  $K$  is to be expressed in ordinary dynamic units. Hence finally

$$K = \Gamma \cdot \frac{2\pi\rho^2}{(n-1)(n-3)(n-4)} \cdot \frac{1}{s^{n-4}}$$

The quantity  $K$  is called the Laplace pressure or intrinsic pressure. More generally we could assume that the force between elementary volumes is  $f(r)$ . The successive integrals then become

$$2\pi a \int_a^\infty f(r) dr dy = 2\pi a \phi(a) dy$$

$$2\pi dy \int_0^\infty a \phi(a) da = 2\pi dy \psi(y)$$

$$K_0 = 2\pi \int_0^\infty \psi(y) dy$$

where  $\phi a$ ,  $\psi y$  are written as the values of successive integrals. Finally  $K$  is obtained in ordinary units by multiplying by  $\Gamma\rho^2$ . For example if  $f(r) = e^{-kr}$  where  $k$  is a constant we have

$$\psi(s) = \frac{ks + 1}{k^2} e^{-ks}$$

The difficulty in testing these equations arises from the occurrence of three variables ( $k$ ,  $s$ ,  $\Gamma$ ). The only one whose value is known independently is  $s$  which for liquids must be of the same order as the molecular diameter. Caution is necessary in considering forces that vary as greatly with distance as cohesive forces undoubtedly do. A small error in the assumed value for  $s$  would lead to very considerable error in  $k$  and  $\Gamma$ . The intrinsic pressure at the breaking point of a solid in tension should be the breaking stress itself. The latter as actually measured is, however, only a lower limit of  $K$  since flaws in the material and irregularities in the application of the tension will lead to fracture occurring at a value lower than the ideal stress (*see SOLID STATE PHYSICS*). The effect of cohesion on the characteristic equation of a gas was allowed for by van der Waals who, following Laplace, took the intrinsic pressure as varying with the density square alone. The equation becomes

$$(p + ap^2)(v - b) = RT$$

between the surface  
of a  
which  
the volume of  
the same  
446

FIG. 3

surface tension, a term  $b$  is introduced to represent the fact that the effects of the gas cannot be reduced to zero. Here  $K = a\rho^2$  of the water at ordinary densities is between 10–20 atmospheres. The fact that the equation turns out to be approximate only makes caution necessary. Moreover  $a$  is found to vary nearly inversely as the absolute temperature. We are obliged to assume, therefore, either that  $\Gamma$  is a function of the temperature or, what is more likely, that  $s$  is such a function. The latter assumption is indeed a very plausible one, for the least average distance of approach of the molecules must be affected by the motion of agitation amongst them and this increases as the square root of the absolute temperature.

Besides these considerations it must be pointed out that this modification only partly allows for the effects arising from the molecular character of matter. If the forces between two molecules at a given distance apart are known, the actual value of the intrinsic pressure could only be correctly obtained by summing up the components (normal to the interface at which the pressure is being calculated) of all the forces between every pair of molecules, each being calculated for the actual instantaneous positions of the molecules. With forces that vary so fast with distance the important molecules are those that are fairly near any given point; the contributions of the remainder may be estimated by an approximate method such as that followed by Laplace. If it is assumed (as experiment suggests) that the force may vary up to the inverse seventh power of distance, the force between molecules that are neighbours and those that are next door to neighbours will be as  $2^7$  to 1 (i.e., in the ratio 128 to 1) or that between any layer and the next and next but one contiguous layer as  $2^6$  to 1 (i.e., in the ratio of 64 to 1). Hence all but a small percentage of the intrinsic pressure is due to the molecules in a small volume surrounding the point. This conclusion signifies that in any material (gas, liquid, solid) the intrinsic pressure will be uniform at all points except for a thin layer of usually negligible volume near its boundary.

**Theory of Surface Forces.**—This surface layer has theoretically no inner boundary but it may be taken, for most purposes, as being only a few molecules thick (molecular diameter is of the order of  $10^{-8}$  cm.). The most prominent peculiarity is that it possesses more potential energy than the rest of the body per unit volume.

Now increase of so-called free (Gibbs) energy (see THERMODYNAMICS) at constant temperature is equal to the external work done on a system. If we write  $dW = \sigma dA$ ,  $\sigma$  is called the surface tension. To determine its value theoretically we estimate  $dW$  for the formation of a surface of unit area. Now if a body is split by a plane section and the two halves separated, a fresh surface is formed. The attraction per unit area between the halves at any distance  $x$  may be given as

$$2\pi \int_0^\infty \psi(y) dy = K(x)$$

The total work of separation is  $\int_0^\infty K(x) dx$  and in the process a fresh area of 2 units is formed. Hence expressing the work done in ordinary units

$$2\sigma = 2\pi\Gamma\rho^2 \int_0^\infty K(x) dx$$

If a power law is taken as the law of force between molecules it follows that

$$\sigma = \frac{\pi\rho^2\Gamma}{(n-1)(n-3)(n-4)(n-5)s^{n-6}}$$

This law may be combined with that for  $K$  with the result that

$$\frac{K}{\sigma} = \frac{2(n-5)}{s}$$

For water at ordinary temperature (approximately)

$$K = 10,000 \text{ atm.} = 10^{10} \text{ dynes/cm.}^2$$

$$\sigma = 75 \text{ dynes/cm.}$$

$$s = 4 \times 10^{-8} \text{ cm.}$$

$$\text{Whence, } n-5 = \frac{10^{10} \times 4 \times 10^{-8}}{2 \times 75} = \frac{8}{3}$$

and

$$n = 7.67$$

It must not be forgotten, however, that  $K$  and  $s$  are obtained by very approximate methods only.

**Interfacial Tensions.**—When liquids 1 and 2 (composed of different species of molecule) are in contact, there is in general a surface tension at the interface which is called interfacial tension. Denoting this as  $\sigma_{12}$ , the tensions of the liquids as  $\sigma_1$  and  $\sigma_2$  respectively, and carrying out a separation of the two liquids, the value of  $\sigma_{12}$  can be determined. In the above process the interface between 1 and 2 disappears and two fresh surfaces appear at which the tensions are  $\sigma_1$  and  $\sigma_2$ . Hence

$$\sigma_1 + \sigma_2 - \sigma_{12} = 2\pi\rho_1\rho_2 \int_{\frac{s_1+s_2}{2}}^\infty K(x) dx$$

where the lower limit is the sum of the radii of the two kinds of molecule. Hence

$$\sigma_{12} = \pi\rho_1^2 F(s_2) + \pi\rho_2^2 F(s_1) - 2\pi\rho_1\rho_2 F\left(\frac{s_1+s_2}{2}\right)$$

If the power law is valid and is the same law for different substances the equations given here lead to

$$\sigma_{12} = \left( \frac{\rho_2^2}{\sigma_2^{n-5}} + \frac{\rho_1^2}{\sigma_1^{n-5}} - \frac{2\rho_1\rho_2}{\left(\frac{s_1+s_2}{2}\right)^{n-5}} \right) \frac{\pi}{(n-1)(n-3)(n-4)(n-5)}$$

All surface tensions with which we have to deal are interfacial tensions since a liquid is always in contact with its own vapour or the gas in which it is immersed. The effect due to the gas is known, however, to be very small.

The normal pressure to be expected from the existence of a superficial tension may be given in the example of a cylinder. Consider an element of surface  $ds$ ; the tensions acting at its extreme edges are inclined to one another and have a resultant inwards (fig. 4). Their resultant is a normal force  $2\sigma \sin \frac{d\theta}{2}$  or in the

FIG. 4

limit  $\sigma d\theta$ . But  $\frac{ds}{d\theta} = R$  (the radius of curvature); hence the normal force is  $\sigma \frac{ds}{R}$ . Since this

acts over an area equal to  $ds$ , the

normal pressure is  $\sigma/R$ .

If we take a body of any shape and select a square-bounded element of the surface, the tensions in the plane of the diagram are equivalent to a normal force  $\sigma ds_1 \times \frac{ds_2}{R_1}$  and those acting on the other two edges to  $\sigma ds_2 \times \frac{ds_1}{R_2}$ . Hence per unit area

$$p = \sigma \left( \frac{1}{R_1} + \frac{1}{R_2} \right)$$

Here  $R_1$  and  $R_2$  are the radii of curvature in two planes at right angles. Owing to Gauss's theorem of integral curvature the sum of two such curvatures at a point is a constant. The above theorem therefore holds whether the two rectangular planes considered are principal planes or otherwise. In the case of a sphere

$$p = \frac{2\sigma}{R}$$

**Effect of Temperature.**—The variation of surface tension with temperature was not taken into account in Laplace's theory. The forces between molecules were taken, like gravitational forces, to be independent of temperature. The rise in a capillary tube was supposed to vary merely because the density varied. Experiment has shown, however, that the tension itself in all cases diminishes with rise in temperature. That it will tend to diminish to

zero can be inferred from the notion that at the critical state a liquid and its vapour will become identical; the tension at the interface must then be zero. R. Eotvös introduced the conception of molecular surface tension. By somewhat doubtful reasoning he concluded that  $\sigma(Mv)^{\frac{1}{3}}$  (where  $Mv$  is the molecular volume) plotted against temperature should give the same kind of curve for different substances, and he found that it was representable by  $K(T_c - T)$  where  $T_c$  is the critical temperature and  $K$  a constant. Empirically, however,  $K$  varies between 1.5 and 2.6 and it is necessary also to change  $T_c - T$  to  $T_c - T - \delta$  where  $\delta$  is a small constant, so that the law is only a rough one. According to this equation the curve would be a straight line cutting the temperature axis a few degrees below the critical point.

In connection with this, remember that  $\sigma$  is only the so-called free energy per unit area and not the total energy per unit area ( $u$ ). Lord Kelvin was the first to show that, in the variation of  $\sigma$  with temperature,  $u$  must be greater than  $\sigma$ ; in other words, when an expansion of the surface takes place heat energy must be added to keep the temperature constant. The connection between these

quantities he showed thermodynamically to be  $u = \sigma - T \frac{d\sigma}{dT}$ .

Now, at the critical point,  $u$  (which is only the extra energy due to the existence of unit surface and not the total energy of the whole body) must also vanish. But if both  $u$  and  $\sigma$  are then zero

so also must  $T \frac{d\sigma}{dT}$  be zero.

Hence, if our conceptions of the critical state are correct the curve of  $\sigma$  plotted against  $T$  instead of being a straight line must become horizontal at the critical point. In 1894 van der Waals showed that a formula of the type  $\sigma = A(T_c - T)^n$  was to be expected and gave the average value of  $n = 1.27$  as deducible from the experimental values. In 1916 A. Ferguson (*Phil. Mag.*, Jan, 1916), examining the data for 14 different organic substances, showed that the best values of  $n$  ranged from 1.187 to 1.248. The advantageous character of this power equation is that it

makes  $\sigma$ ,  $u$ , and  $\frac{d\sigma}{dT}$  all equal to zero at the critical point and it thus satisfies all that is required of it theoretically.

Liquids, however, do not follow the above simple law. The surface energy  $u$  also falls to zero at the critical point, but accord-

ing to a different law. For taking the equation  $u = \sigma - T \frac{d\sigma}{dT}$

it follows that  $u = A(T_c - T)^{n-1} (T_c + [n-1]T)$ . Curve B for  $\sigma$  and curve A for  $u$  are shown in fig. 5 for the case of benzene.

The figure shows how nearly a straight-line law satisfies the values of  $\sigma$  until the critical point is closely approached. An interesting relation was given by E. T. Whittaker between  $u$  and the latent heat (internal) of evaporation. The internal latent heat ( $L_i$ ) is obtained by subtracting the external work done from the ordinary latent heat. The relation in question is that  $\frac{T_c}{T} \cdot \frac{u}{L_i}$  is

nearly a constant, and that (in cgs units) this constant is about unity for ethyl oxide, methyl formate, benzene, and chlorobenzene, and about 2 for carbon tetrachloride. The degree of constancy is indicated in the following table for benzene (critical temperature about 561.5° K).

$T^\circ\text{K}$	$\frac{T_{cm}}{TL_i}$	$T^\circ\text{K}$	$\frac{T_{cm}}{TL_i}$

FIG. 5

BY COURTESY OF THE FARADAY SOCIETY

The relation indicates a close connection between the surface energy and the volume energy of the substances.

**General Properties of Surface Tension.**—The tension of a liquid across any straight line drawn on the surface is normal to that line and is the same for all directions of the line. It is measured by the force across an element of the line divided by the length of that element.

For any given homogeneous liquid surface, as the surface that separates water from air or oil from water, the tension is the same at every point of the surface and in every direction. In the case of mixtures, however, when circumstances demand it (e.g., when the surface is inclined and the effects of a gravitation field require consideration) the concentration at the surface may adjust from point to point to produce a corresponding variation in surface tension to produce equilibrium. This effect is very minute and in most problems may be ignored.

When the surface is curved the effect of the surface tension is to make the pressure on the concave side greater than that on the convex side by  $\sigma(C_1 + C_2)$  where  $C_1$  and  $C_2$  are the curvatures in mutually perpendicular normal planes.

The tension of the surface separating two liquids cannot be deduced by any reliable method from the tensions of the liquids when separately in contact with air.

The experiments of C. G. M. Marangoni, van der Mensbrugghe, and Quincke show that the common surface between two liquids has a tension always less than the difference of the tensions of the separate liquids. This is usually referred to as Marangoni's rule.

If three liquids meet along a line the interfaces at the common edge must be parallel to the sides of a triangle proportional to the three tensions  $\sigma_{12}$ ,  $\sigma_{23}$ ,  $\sigma_{31}$ ; otherwise equilibrium cannot obtain (Neumann's rule). This triangle cannot exist unless two of the interfacial tensions are greater than the third. Marangoni's experimental rule shows that the triangle is always imaginary. Hence three pure fluids (of which one may be a gas) accordingly cannot remain in contact. If a drop of oil stands in a lenticular form upon a surface of water, it indicates that the water surface is already contaminated with a greasy film.

When a solid body is in contact with two fluids (fig. 6) the surface of the solid cannot alter its form but the angle at which the surface of contact of the two fluids meets the surface of the solid will depend on the values of the three surface tensions. For equilibrium

$$\sigma_{31} - \sigma_{23} = \sigma_{21} \cos \alpha$$

The angle  $\alpha$  is known as the angle of contact. For pure substances the angle of contact varies from 0° (or very nearly so) for liquids that "wet" the solid to 130° or 140° for mercury in contact with glass.

In regard to the experimental behaviour of water on mercury the wealth of papers is equalled by the remarkable lack of uniformity in the results obtained even when elaborate precautions are taken. A drop of water that fails to spread when placed on a mercury surface often will spread when the mercury is poured out of the dish—thus involving the production of a new surface.

**Form of a Capillary Surface.**—The form of the surface of a liquid acted on by gravity may be determined if it is assumed that near the liquid-solid interface it is straight and horizontal. This will be the case, for example, near a flat plate dipped into the liquid.

Let  $A_2P_2$  in fig. 7 be the vertical plate supposed to be so wide that the edge effects do not count. Consider the forces per unit depth (perpendicular to the paper) and consider  $A_1A_2$  as the standard level of the liquid far from the plate. The curvature of the surface at the point  $x, y$  ( $P_1$ ) is

$$\frac{d\theta}{ds} = \sin \theta \frac{d\theta}{dy} = -\frac{d(\cos \theta)}{dy}$$

and consequently the pressure in the liquid at that point is less

FIG. 6

than the pressure outside it by  $-\sigma \frac{d(\cos \theta)}{dy}$ . But the pressure is less than that at a distant point where the surface is flat by  $gpy$  or  $g(\rho - \rho_0)y$  if allowance is made for the surrounding gas. Hence the differential equation for the surface is

$$-\frac{d(\cos \theta)}{dy} = \frac{g(\rho - \rho_0)}{\sigma} y$$

the integral of which is  $1 - \cos \theta = 2 \sin^2 \frac{\theta}{2} = \frac{g(\rho - \rho_0)}{\sigma} \cdot \frac{y^2}{2}$ . The

shape of the surface is therefore the elastica; i.e., the form taken by a uniform spring when equal and opposite forces are applied at its ends. The equation might have been found by considering the elementary volume  $dx$  of a strip of liquid sustained above the normal level of the liquid by the surface forces at its outer and inner edges. The difference of the vertical component of these is  $\sigma d(\sin \theta)$  and the weight of the strip is  $gpydx$  but since  $\frac{d(\sin \theta)}{dx} = -\frac{d(\cos \theta)}{dy}$  the same result is obtained.

If the angle of contact is  $\alpha$  the value of  $\theta$  at the plate is  $\frac{\pi}{2} - \alpha$ ;

hence  $1 - \sin \alpha = \frac{g(\rho - \rho_0)}{\sigma} \cdot \frac{Y^2}{2}$

which gives the greatest height through which the liquid is raised. A thin sheet of glass suspended from the arm of a balance and just dipping into a liquid provides a simple way of determining the surface tension.

The increase in the apparent weight of the sheet when the liquid has been raised by capillarity is  $\sigma$  multiplied by twice the horizontal length of the sheet. An unusually sensitive form of this apparatus is known as Worthington's multiplier, a special piece of equipment in which the strip is rolled into a vertical cylindrical spiral.

**Ascent up a Capillary Tube.**—A capillary tube dipped in a liquid provides a simple method of determining surface tension. To connect the surface tension with the rise (or descent) of the liquid in the tube measured from the level part of the outside surface, equate the effective weight of the liquid raised to the total force due to the tension. The effective weight (with the symbols shown in fig. 8) is

$$g(\rho - \rho_0) \int_0^r 2\pi x(h+y)dx$$

for an inner cylinder of radius  $x$  where  $\rho$  is the density of the liquid and  $\rho_0$  that of the surrounding gas or vapour. The vertical component of the surface force acting all around the edge of the liquid surface of this cylinder is  $2\pi x \sigma \sin \theta$  or  $2\pi x \sigma \cos \alpha$  where  $\theta$  is the angle between the surface and the horizontal and  $\alpha$  is the contact angle which is measured with respect to the solid surface (in this case the vertical). These two expressions are to be equated to one another.

Neglecting  $y$  altogether compared with  $h$  and integrating between the limits 0 and  $r$  gives  $2\pi r \sigma \sin \theta = g(\rho - \rho_0) \pi r^2 h$  whence  $\sigma \sin \theta = \frac{1}{2} g(\rho - \rho_0) r h$ . For a better approximation first differentiate the two sides of the equation; whence

$$\frac{d(x \sin \theta)}{dx} = \frac{g(\rho - \rho_0)}{\sigma} x(h+y) = \frac{x(h+y)}{\beta^2}$$

This may be considered as the standard exact equation. The left

side is  $\frac{xd \sin \theta}{dx} + \sin \theta$  or  $x \left( \frac{\cos \theta d\theta}{dx} + \frac{\sin \theta}{x} \right)$

But  $\cos \theta \frac{d\theta}{dx} = \frac{d\theta}{ds}$  (where  $ds$  is an element of the curve  $AC$ )

and is therefore the curvature in the plane of the diagram at  $B$ ; and  $\frac{\sin \theta}{x}$  is the curvature of the surface at  $B$  in a plane at right angles

to the diagram. Hence, calling these curvatures  $\frac{1}{R_1}$  and  $\frac{1}{R_2}$

$$\sigma \left( \frac{1}{R_1} + \frac{1}{R_2} \right) = g(\rho - \rho_0) (h+y)$$

Both of the terms here are expressions for the difference of pressure between the two sides of the surface at the point  $B$ .

**Narrow Tubes.**—The equation shows that the sum of these curvatures increases with the height; but when  $h$  is large and  $y$  small, as it is for a very narrow tube, the sum is nearly constant. Going back to the differential form of the equation and taking the case where the liquid wets the tube, the curve may be considered as practically circular, of radius  $r$ ; the corresponding value of  $y = r - \sqrt{r^2 - x^2}$  and

$\frac{d(x \sin \theta)}{dx} = \frac{1}{\beta^2} (h+y)x = \frac{x}{\beta^2} (h+r - \sqrt{r^2 - x^2})$  nearly whence, by integration

$$x \sin \theta = \frac{1}{\beta^2} \left[ \frac{hx^2}{2} + \frac{rx^2}{2} + \frac{1}{3} \{ (r^2 - x^2)^{\frac{3}{2}} - r^3 \} \right]$$

or since  $\sin \theta = 1$  when  $x = r$

$$1 = \frac{r}{2\beta^2} \left( h + \frac{r}{3} \right)$$

By putting the radius of the circle as  $R = \frac{r}{\cos \alpha}$  when the angle of

contact is  $\alpha$  instead of zero this becomes

$$\cos \alpha = \frac{r}{2\beta^2} \left[ h + \frac{r}{3 \cos^3 \alpha} \{ 1 - 3 \sin^2 \alpha - 2 \sin^3 \alpha \} \right]$$

By calculating  $\tan \theta$  from  $\sin \theta$  and noting that

$$\tan \theta = dy/dx,$$

we can by subsequent integration obtain a closer value of  $y$  in terms of  $x$  which can, in turn, be introduced into the differential equation, and so on. By such successive approximations Lord Rayleigh obtained the equation for the case  $\alpha = 0$  in the form

$$\sigma = \frac{1}{2} g(\rho - \rho_0) h r \left[ 1 + \frac{1}{3} \frac{r}{h} - 0.1288 \frac{r^2}{h^2} + 0.1312 \frac{r^3}{h^3} \right]$$

in which the coefficients are claimed to be correct to the approximation given. The equation can only be used in the case when  $r$  is small compared with  $h$ . It may be mentioned that a very near approach to the equation can be obtained by considering the surface as ellipsoidal with its minor axis vertical.

Various methods are employed for determining surface tension experimentally:

(a) From the rise in a capillary tube making use of the above equation.

(b) *Sentis' Method.*—A capillary tube is partly immersed in the liquid. It is then withdrawn vertically and a drop remains clinging to the lower end; the position  $A$  of the vertex of the drop is noticed (fig. 9). The liquid in the vessel is then raised until it touches the vertex (when the column falls) and then raised further till the upper surface is at the same level  $C$  as at first. The liquid in the vessel is then at the level  $B$ . The vertical dis-

FIG. 7

FIG. 8

FIG. 9

tance AB corresponds to  $h$  in the ordinary method but in the correcting terms  $h$  must be put negative. The width of the drop is in this case to be small compared with  $h$ .

(c) *Jaeger's Method*.—In this method an orifice (a "tip") is placed just under the surface of the liquid and the pressure of gas is increased until bubbles form. The maximum pressure of the gas (which is fairly sharply marked) is observed. The deduction of the applicable equation is a somewhat delicate matter because the problem is really kinetic, not static. The formula employed is

$$\sigma = \frac{p_{\max} r}{2} \left[ 1 - \frac{2}{3} \frac{r}{h} \right]$$

where  $p_{\max}$  is the maximum difference of pressure between the level of the end of tube inside and outside, and  $r$  is the internal radius of the tube. The bubble is assumed to form within the internal circumference. In practice, however, it sometimes forms on the outside circumference. To obviate the uncertainty it is recommended to make the two circumferences as nearly equal as possible, but this is an experimental matter of great difficulty. The final accuracy depends chiefly on the measurement of the radius  $r$ .

(d) *Drop-Weight Method*.—This method is connected with the preceding one because the drops considered are those issuing from a narrow tube. Other things being the same, the weight of a drop of liquid is proportional to the diameter of the tube in which it is formed. Quincke gave the value  $2\pi r\sigma$  as the weight of the suspended drop just before falling provided that the inflow of liquid is sufficiently slow. A portion of the drop is always left behind when the main part falls; but he considered that it might be neglected in the case of very small drops.

Lord Rayleigh discussed the question from the dimensional point of view (see DIMENSIONAL ANALYSIS). Assume that the mass  $M$  of the drop depends only upon the surface tension  $\sigma$ , the value of acceleration due to gravity  $g$ ; the density of the liquid  $\rho$ , and the inside radius  $a$  of the tube. Rayleigh showed that  $\sigma a/g$  has the same dimensions as a mass and that  $\sigma/g\rho a^2$  is a dimensionless number. Since quantities that can be equated must be of the same kind, it follows that  $M \propto (\sigma a/g) F(\sigma/g\rho a^2)$  where there is no restriction, imposed by this method of inquiry, on the function  $F$ . Rayleigh found by experiment that  $gm/\sigma a$  is fairly constant for wide ranges in the diameter of the tube. For thin-walled tubes in the case of water the following values were obtained:

$\frac{\sigma}{g\rho a^2}$	$\frac{gM}{\sigma a}$	$\frac{\sigma}{g\rho a^2}$	$\frac{gM}{\sigma a}$
2.58	4.13	.277	3.78
1.16	3.97	.220	3.90
.708	3.80	.169	4.06
.441	3.73		

The mean value of the constant is thus about 3.8 instead of  $2\pi$  as estimated by Quincke. Further experiments by others showed that the constant approaches Quincke's value as the diameter becomes very small.

As a means for measuring surface tension this method is obviously not satisfactory; but for rough comparative values for liquids of like kind it is very quick and easy. When  $a$  is not small the approximations made for narrow tubes are not suitable.

**Bubbles and Drops.**—These can be dealt with by similar methods. Minute air bubbles in a liquid are nearly spherical; they tend to become flat with increasing size (fig. 10). The excess pressure  $p - p_0$ , which can be found by experiment, determines the total curvature at the lowest point  $N$ ; the curvature is equal to  $2/R$ . If  $y$  is reckoned upward as before, then

$$\frac{d(x \sin \theta)}{dx} = \left( \frac{2}{R} + \frac{y}{\beta^2} \right) x$$

thus  $2/R$  replaces  $h/\beta^2$  in the preceding problems. For very large

bubbles, as for wide tubes, a good approximation can be obtained by neglecting the second curvature and also  $2/R$ , so that

$$(1 - \cos \theta) = \frac{y^2}{2\beta^2} = 2 \sin^2 \frac{\theta}{2}$$

If  $H$  is the value of  $y$  for which the tangent to the curve becomes vertical, then  $H = \sqrt{2}\beta$ . This method was used by Quincke and others but not always with bubbles large enough to justify the approximation. The bubble is conveniently formed under a slightly concave surface to prevent it from escaping. Drops of mercury are easily formed above a concave surface. If  $y$  is measured downward from the summit the same equations hold as for bubbles.

These methods have been used in determining surface tension. Through infinite series calculated for each of the variables each term in the differential equation can be calculated to very high accuracy, and tables are drawn up from which the form can be determined for given weights of material and given surface tensions.

**Thin Films.**—One group of thin films consists of those in which the substance forms a thin sheet with gas on both sides, as for example, a soap bubble. In this case there are always two surfaces to consider. When the thickness is considerably greater than the value of the range  $e$  of molecular forces, the two surfaces are independent of one another; the surface tension must then have the usual value for each. For very thin films this will not hold. If the thickness is less than the range  $e$ , the tension for each surface will be less than the normal value. When the variation of density at different levels in the film is taken into account, reduction in surface tension will begin when the thickness is twice  $e$ .

A soap film is a small quantity of soap solution spread out to present a large surface to the air. The addition of glycerol and resin permits more permanent films to be prepared. Bubbles may easily be blown 20 in. in diameter in the open air using a clay pipe or a small glass funnel. Sir James Dewar obtained bubbles that lasted almost indefinitely, preventing evaporation by blowing them in a confined space saturated with water vapour.

The pressure inside a bubble is greater than that outside by  $2\sigma \left( \frac{1}{R} + \frac{1}{R} \right)$ ; i.e., by  $4\sigma/R$  where  $R$  is the radius of curvature. The factor 2 arises because both surfaces give rise to normal components of forces. This result is obtained by considering the equilibrium of each half of the bubble. The force at the cut edge is  $2\sigma 2\pi R$ , and this is balanced by the excess pressure acting over the plane area  $\pi R^2$ . Hence the excess pressure is

$$\frac{2\sigma \cdot 2\pi R}{\pi R^2} = \frac{4\sigma}{R}$$

If the end of the pipe or funnel is opened, the bubble will contract because of the escape of high pressure air from inside. As it contracts, the pressure paradoxically increases. It may be added that (neglecting gravity) the bubble is spherical, since this shape minimizes the surface area (and therefore the potential energy) for a given volume.

If bubbles are blown on the expanded ends of two funnels (the stems being stopped by the fingers), they can be made to coalesce by carefully bringing them into contact. (A slightly electrified rod brought not too near will assist the coalescence.) On drawing the funnels slowly apart a cylindrical bubble is obtained. The excess pressure is now  $2\sigma/R$  where  $R$  is the radius of the opening of the funnel. On further separation the cylinder will contract in the middle; one of the two curvatures is now negative, giving what is called an anticlastic surface. With further extension of length the surface becomes unstable and the film collapses. It has been shown by Maxwell that a cylindrical film becomes unstable when its length is greater than its circumference.

**Films on Liquids.**—In another group of thin films a liquid or solid is on one side and a gas on the other. To this group belong all cases of the spreading of oil or other substance on water or other liquid or solid. This old familiar subject has great importance in its bearing on molecular structures. The first

BY COURTESY OF THE FARADAY SOCIETY

FIG. 10

FIG. 11

to experiment in detail on such films was F. H. R. Lüttge, who showed how a film of high surface tension is replaced by one of lower surface tension. Akin to these are experiments made on the erratic movements observed when fragments of camphor are sprinkled on a clean water surface. A trace of grease as communicated to the surface by dipping a finger in the water can practically stop this motion. The thickness of oil that is required has been called the camphor point. Lord Rayleigh showed that the thickness of a film of olive oil that corresponds to the camphor point is about  $2 \times 10^{-6}$  mm.; i.e., it is only a moderate multiple of the diameter of a gaseous molecule and scarcely exceeds the diameter of a molecule of oil.

By means of a movable slider on water (the surface tension being measured by means of the attraction on a small disc) the contaminating material on the surface can be squeezed. Such experiments indicate that the water surface can exist in two sharply contrasted conditions: the normal condition, in which the displacement of the partition makes no impression on the tension; and the anomalous condition, in which every increase or decrease (of the surface) alters the tension. Lord Rayleigh used a similar apparatus to conclude that the first drop in tension corresponds to a complete layer one molecule thick and that the diameter of a molecule of oil is about  $1.0 \times 10^{-6}$  mm.

By measuring the surface area that can be completely covered by a weighed quantity of material, I. Langmuir determined both the cross-sectional area and the length of a molecule and showed that the length for organic molecules like those of palmitic, stearic, and cerotic acids is nearly five times the breadth, while in cetyl palmitate it is nearly ten times. He and N. K. Adam measured the amount of "oil" and measured directly the force required to compress the oily surface to any given area with a floating barrier. It was found that when the molecules in the film are widely separated from one another the force due to the film is an expansive one.

This cannot be explained through Laplace's theory; it is necessary to allow for the effects of thermal motion; the film in such a case is analogous to a two-dimensional gas. If the barrier is moved gradually to compress the film, successive changes take place. Fig. 11 shows these for a film of myristic acid on weak HCl (N/100). The unit of area is a square angstrom (i.e.,  $10^{-100}$  sq.m.), and the area specified is that occupied by one molecule of the acid. The ordinates of the curves are the difference of the tensions on the two sides of the barrier. The curves are isothermals extending from 2.5° to 34.4° C. They exhibit some of the characteristics of the  $p, v$  curves for a condensable substance. At high temperatures the curves appear to be approximately rectangular hyperbolas. For small values of the area they approach the form for liquids. At intermediate stages, however, there is

no constant pressure isothermal as in the analogous case of the vapour pressure of a liquid below the critical point. The form is more nearly that for the vapour pressure of a mixture of two liquids (see SOLUTIONS). This suggests that the underlying water takes a part in the changes.

It is not to be expected that there should be complete correspondence between the two classes of phenomena. However, the effects of thermal motions in the films cannot be neglected. The analogy with liquids and gases can be further illustrated by plotting  $AF$  against  $F$ , where  $F$  is the force applied per unit length. It is clear from fig. 11 that a film of myristic acid can be squeezed up until a molecule occupies less than 24 square angstroms. At the opposite end where the behaviour approaches that of a gas it is to be expected that the equation will take the form  $AF = RT$  where the value of  $R$  (allowing for only two degrees of freedom) should be 1.372 per molecule; at room temperature, therefore,  $AF$  should be about 400. This has been experimentally verified as a limiting value for very low surface pressures. With the long-chain fatty acids, esters, and nitriles it is approached within 25%, the pressure being below 0.1 dyne per square centimetre. With the dibasic ester  $C_2H_5OOC(CH_2)_{11}COOC_2H_5$  it has been verified within 10%.

A simple gas analogy should not be pressed too far, however. A thin film on a body of different material cannot be treated as being in a similar state to the molecules in the body of a gas. Forces between the film and the liquid beneath must also be considered. These may account for the fact that some films do not spread indefinitely as a gas expands into a vacuum. Further, the most compressed state can only give an upper limit to the least cross-sectional area of the molecule. The molecules are resting on the rapidly moving molecules beneath them and share in their agitation. Still, these investigations throw light on the nature of films and on the dimensions of molecules. Where corroboration is possible, measurements made by X-rays are in good accord with those obtained by this method.

**SURF RIDING**, a sport originating in Hawaii, is now enjoyed on the open ocean coastlines throughout the world. Best conditions occur where large, smooth ocean swells in deep water peak up into steep-sided sets of waves or breakers as they encounter a shelflike reef or sandbar 100 to 1,000 yd. out while approaching the shore. The lee side of a point of land or a jetty often has the proper bottom contour for good surfing waves. Under ideal conditions, as at Makaha, Hawaii, with 14-ft. waves, rides of over half a mile are obtained.

Where surf is light, flat boards 4 to 6 ft. (122 to 183 cm.) long by a foot wide are used. For waves up to 20 ft. (610 m.) in height a tapered hollow surfboard 10 to 12 ft. (305 to 366 cm.) long and

BRUCE DAVIDSON—MAGNUM

SURF RIDING IN CALIFORNIA

2 ft. (60 cm.) wide, with a stabilizing fin, or skeg, near the back, is used. The rider first swims out to the point where the larger rollers peak up, but before the crest breaks. As the wave approaches him, he paddles his board toward shore to attain sufficient speed to start to coast down the face of the wave. Once he has caught the wave, he may rise to a standing position and ride it until it dies out near the beach. To increase speed and distance experts ride diagonally toward shore.

National and international competitions have been held on both coasts of North America, Peru, Hawaii, and eastern Australia. Groups of 5 to 12 competing surfers with numbered shirts perform in the same area. They are judged on a point system for takeoff, turns, length of ride, and difficulty of wave selected.

The wakes of heavier outboard and inboard motorboats driven at speeds of 9 to 13 mph provide waves of sufficient strength for less difficult "surfing" on inland lakes and rivers. This inland surfing, in which a whole family can participate, plus the development of plastic foam, fiberglass coated boards at popular prices accounted for rapid growth in popularity of the sport. For wake riding, boards about 8 ft. long are used. The rider starts with a towline from the boat and lets it go when he feels the wake pushing him.

(J. AN.)

**SURGE**, in general terms, is a sudden increase to an excessive or abnormal value and a subsequent fall from such a value. In meteorology, "surge" is the name applied to those long-period progressive changes of barometric pressure that occur simultaneously at many locations over a wide region and that are superimposed on short-period pressure fluctuations of a diurnal nature or variations caused by traveling atmospheric disturbances of a local character. A pressure rise or fall of two millibars in 24 hours that occurs simultaneously within an area of 3,000,000 sq.mi. (7,750,000 sq.km.) corresponds to the order of magnitude of the phenomenon. Such pressure surges are commonly noted in regions close to the large semipermanent pressure centres of the earth, such as the high-pressure area of the southern North Atlantic Ocean. "Surge" is also a meteorological term often applied to a sudden increase in velocity of the large atmospheric wind streams, especially in the tropics. Such a wind surge occurs simultaneously over a large area and frequently spreads from place to place so that its progress can be followed on weather maps. In the trade-wind belts, meteorologists frequently refer to this event as the "surge of the trades" and, in the regions of the monsoon currents, as the "burst" or "surge of the monsoon." At a given location, an increase of wind speed from about 10 to 35 mph (16 to 56 km.ph) or more at all levels from the ground up to approximately 15,000 ft. (4,600 m.) can be expected in connection with a well-marked surge of the trades.

**SURGERY (ARTICLES ON):** see MEDICINE AND SURGERY (ARTICLES ON).

**SURGUJA**, a district in the northeastern part of Madhya Pradesh, India. Area 8,626 sq.mi. (22,341 sq.km.). Pop. (1961) 1,036,738. In the central part there is fairly well-cultivated country, surrounded on the north, east, and south by massive hill barriers and tablelands. A long, winding ridge, the Jamirapat, forms part of the eastern boundary and separates the district from the Chota Nagpur Plateau. The southern barrier of Surguja is the Mainpat tableland, which rises to a height of 3,700 ft. The majority of the population is made up of a great variety of aboriginal tribes. The chief town is Ambikapur (pop. [1961] 15,240). Crops include rice and oilseeds, mainly in the valleys of the south-west. There are considerable coal deposits, and iron ore, limestone, and bauxite are also found. The Ramgarh Hill, a rectangular mass of sandstone rising abruptly from the central plain, contains a remarkable natural tunnel, many rock caves, and remains of temples made of enormous blocks of stone. Most important among its antiquities are the Sitabenga and Jogimara caves, which contain inscriptions in the Brahmi script dating from the early 1st century B.C. and wall paintings of similar age. These paintings are thought to be among the oldest surviving in India. Other ruins in the jungles indicate a high state of civilization in later centuries, but these have never been described adequately. Surguja, formerly one of the Chhattisgarh states, ruled over

by a Rajput family, was merged with Madhya Pradesh in 1948. The state had been ceded to the British in 1818. (F. R. A.)

**SURINAM** (SURINAME in Dutch), Dutch Guiana, or Netherlands Guiana, a fully autonomous part of the Netherlands Realm, lies between Guyana and French Guiana. Its area is 63,251 sq.mi. (163,820 sq.km.), and its Atlantic coastline is about 196 mi. (315 km.) long.

**Physical Geography.**—The geology, topography, and drainage of Surinam are similar to those described for Guyana (*q.v.*), but the area of elevated sandstone within Surinam is limited to the Tumuc-Humac Mountains (Serra de Tumucumaque) on the extreme southern frontier and its northward projection, the Eilerts de Haan Mountains, at about 2,500 ft. (760 m.). Except for the coastal area, the territory therefore consists of an ancient crystalline plateau, rarely over 500 ft. (150 m.) above sea level, intensely folded, sloping gently seaward. It is crossed by large parallel rivers, notably the Courantyne (Corantijn), Saramacca, Suriname, and Tapanahoni, which are interrupted by rapids formed by igneous intrusions into the crystalline complex. The plateau is almost wholly covered with dense forest.

The coastal deposits are of marine origin, distributed by currents from the direction of the Amazon. The lower courses of the main rivers have a northwesterly alignment in consequence. The coastal zone is varied by sand dunes and shelly and peaty deposits and is swampy except where it has been drained and made cultivable near the sea and the lower rivers. This limited area remains the chief source of agricultural wealth, though much of it needs rehabilitation of its drainage works.

The climate is tropical, similar to that of Guyana though the coast is slightly wetter. The vegetation and animal life are also similar. For a full discussion, see GUYANA: *Physical Geography*.

**History.**—(For history before 1815, see GUYANA: *History*.)

CARL FRANK FROM PHOTO RESEARCHERS  
CHURCH IN PARAMARIBO, SIMILAR  
TO THOSE IN THE NETHERLANDS

The political history of the 19th century was uneventful. From 1828 to 1848 Surinam and the Dutch West Indian Islands were under a single governor at Paramaribo. About 300,000 West Africans were brought into Surinam between 1650 and 1820.

In the early 19th century Moravian and Roman Catholic missions were active in Surinam, and when slavery was abolished in 1863, almost all the slaves were nominally Christian. For the ten years after emancipation the rights of the freed slaves were severely limited. Thereafter, they could own land, and former plantations were parceled out. Lack of central control, however, led to a breakdown of irrigation and drainage, and this helped drive large numbers of the former

slaves into town life, the mining of bauxite, and emigration. An arrangement with the British for the control of immigrants from India was drawn up in 1870, and the first indentured labourers arrived in 1873. Between then and 1917, when the treaty was abrogated, 34,304 persons arrived, about one-third of whom later returned to India. After 1895 the Surinam government made land ownership possible for these immigrants, and this proved an effective method of keeping them in the country, especially after the introduction of rice growing in 1913. Javanese immigration began in 1890, giving the country a useful body of small farmers. From 1930 to 1939 there was an influx of nonindentured Javanese.

During the 19th century the colony suffered from the concentration of Dutch energies on the East Indies, and there was little real development before 1900. At that date, 90% of all agricultural products were grown on plantations and 10% on small farms; but these figures were completely reversed in the subsequent half-

century, and the plantation crops of cocoa, coffee, sugar, and cotton were replaced by rice and fruit.

The amount of reclaimed land diminished as plantation agriculture declined, but there was considerable development in other directions, stimulated by the influx of financial and technical resources diverted from the East Indies after 1945. In 1954 Surinam became a self governing part of the kingdom of the Netherlands. It also joined the European Economic Community as an Associated Overseas Territory. A ten-year plan, inaugurated in 1955, stressed the economic and social development of the country, and it was in general very effective.

**Population and Peoples.**—The population at the 1950 census was 183,681, and in addition there were about 26,000 Amerindians and Bush Negroes. The provisional total for the census of March 1964 was 324,211, with about 38,000 Amerindians and Bush Negroes. At least seven-eighths of the people lived on the coast and no less than 34% in Paramaribo (pop. 1964, 110,867). The next town in size was Nieuw Nickerie (pop. 1964, 7,396).

The increase in population has been striking; in 1900 the total was less than 70,000. Bush Negroes (Djukas), the descendants of escaped slaves, have been increasing for many years. The Amerindians numbered about 5,000 in the mid-1960s as against about 2,000 in 1942. As in Guyana, Asian Indians were the most rapidly increasing group; they formed about 30% of the total in 1964. The approximate proportions of other racial groups were: Creoles (former African slaves) 41%; Indonesians 13%; Bush Negroes 9%; Amerindians, Chinese, and Europeans about 1.5% each; others 2.5%.

The three main ethnic groups maintain marked differences in social and cultural life. Creole culture, especially in its loose family structure and its matrilineal emphasis, is essentially derived from slave conditions. The Creoles have generally been less successful in smallholding and commerce than the Indians but have made good labourers and artisans. Their readiness to move around the country and to emigrate and their passion for education are important assets, and they have done well in the professions. Creoles preponderate in Paramaribo and Coronie.

The Asian Indians are mostly Hindus but include a Muslim element. In their early years in Surinam they were, as plantation labourers, separated from the Creoles. Their subsequent success as merchants and smallholders, and the threat of their increasing numbers, have kept them apart from the Creoles. They have not assimilated European culture as the Creoles have, and remain a frugal farming and trading community, speaking their own languages and living in strongly organized patriarchal families. Nevertheless, there have been big changes even among the Indian community since 1945, and economic opportunity is tending to make them more assimilated. Indians preponderate in the coun-

try areas of Nickerie, Saramacca, and Suriname, and their farms are mostly of 12 to 124 ac. (5–50 ha.).

The Javanese cultivate smallholdings mainly of less than 10 ac. (4 ha.), most of which are in Commewijne and Suriname. They are the least affected by Western culture of the three main racial groups. They are rice growers and have generally shown little ambition to do anything else. Their religion is nominally Muslim but is intensely ritualistic and has strong pagan overtones. They are generally ignorant of languages other than their own.

**Government and Administration.**—Surinam became part of the Netherlands in 1948. The present constitution was defined by the Realm Statute, effective from Dec. 29, 1954, which confirmed and amplified an interim order of Jan. 20, 1950. Surinam was given self-government except in foreign affairs and defense but has certain rights of choice in international commitments.

The governor, representing the sovereign, is head of the government. He appoints an advisory council of five for life, and a council of nine ministers from the Legislative Assembly (*Staten van Suriname*), which has 36 members elected for four years by adult suffrage. The country is divided into eight districts, of which Paramaribo (*q.v.*), the capital and chief port, is one.

**Social Conditions.**—Of a total labour force of about 100,000, more than half were engaged in agriculture in the mid-1960s, but as smallholdings and family working predominated, figures were very unreliable. Of more than 16,000 holdings, no fewer than 12,000 were less than 10 ac. (4 ha.). Asian Indians farmed 45% of the holdings, Indonesians 14%, and Creoles the rest.

Surinam has a relatively high literacy rate, there having been compulsory education for children 7–12 years of age since 1876. The government provides some schools and aids others. More than half the primary and secondary schools are denominational. There are also a medical school, a law school, technical schools, teacher-training colleges, agricultural courses, domestic science schools, and special schools. Provision is made for children in remote areas, and the needs of children whose mother tongue is not European get special attention.

The health of Surinamers is good by the standards of tropical countries. The crude death rate in the 1960s was about 8.5 per 1,000 of the population.

**Economy.**—About 89,000 ac. (36,000 ha.) of land are under cultivation, of which 49,000 ac. (20,000 ha.) are irrigated. About 15,500 ac. (6,300 ha.) are used as pasture. Perhaps another 155,000 ac. (63,000 ha.) are suitable for crops but are unused. There has been no development of the far interior savanna comparable to that in Guyana.

Of the cultivated area, 75% is devoted to growing rice, which is not only a staple of local diet but forms more than half of the agricultural exports. The main crop is sown from late March to May and is harvested about 140 days later. A second crop is planted on about one-fifth of farms in October or November. Nickerie is the centre of the main rice-growing area.

Citrus fruits (mainly oranges and grapefruit), coffee, cocoa, sugar, and bananas are the other main crops. Only two plantations grow sugarcane, but both are large and well-equipped. Surinam does not possess the labour or skill to compete successfully in world markets for fruit. A great variety of crops is grown for domestic consumption, including coconuts, corn (maize), peanuts, and soybeans, and domestic trade is mainly in foodstuffs. Even so, there is not enough food grown for the town populations, and Surinam must import vegetables and peanuts.

Bauxite is mined in opencast workings at three main sites at Paranam, Onverdacht, and Moengo. The first two are worked by Suralco, a subsidiary company of Alcoa (The Aluminum Company of America), and the third by the Billiton Company, which originally mined tin in the East Indies. The bauxite is mainly exported to the U.S. It is loaded directly to ocean-going vessels at Paranam and Smalkalden, about 20 mi. (32 km.) above Paramaribo; and at Moengo, which is 17 mi. (27 km.) up the Commewijne River and another 69 mi. (111 km.) up the Cottica, involving the navigation of awkward bends. The government and Suralco undertook construction of an aluminum smelter at Brokopondo, using hydroelectricity from the Afobaka dam. Bauxite is
